Two of our best-known engineers and educators, a president and a past-president of this Society, one a dean of colleges of engineering and the other a president of a technical institute, have recently made addresses bearing on the future of the engineer and on what he must expect to do and become, and what viewpoint would seem to be necessary if he is to live up to his full duties and responsibilities. One address was made at Detroit by President Cooley and the other at Ottawa by Past-President Hollis. While in treatment they are different, in their application they point in the same direction, toward the service of the public. Both addresses are reported in this number, the one by Dean Cooley under what he styles " one of the finest titles I ever worked out "—An Unoccupied Rung in the Engineer's Ladder of Fame—and the one by Dr. Hollis under News of the Engineering Societies. Read them.

The headquarters of the A.S.M.E. is favored with frequent visits of members who are either returning from France or are on their way overseas. Recently Major W. B. Gregory, of New Orleans, a member of the Council, returned after 16 months' absence, having been engaged mainly in waterworks construction for supplying the railway lines leading to the western front.

Major Gregory speaks appreciatively of the cordial relations which he experienced among the French people with whom he came in contact; of their appreciation of the service rendered by the Americans; and of their desire to show their gratitude by such means as are at their disposal.

Another visitor was Prof. E. R. Hedrick, of the University of Missouri, who is now on his way abroad to take charge of instruction in mathematics as applied to engineering among the A. E. F. Professor Hedrick will work under the direction of Dean L. E. Reber, Mem.Am.Soc.M.E., of the University of Wisconsin, who is in control of the engineering and trade courses for the soldiers. A brief account of this educational work is given in another column of this issue.

The Spring Meeting

The Spring Meeting, to be held June 16 to 19 at Detroit, with headquarters at the Hotel Statler, will have as its leading professional feature an all-day session devoted to the subject of industrial research—a subject which has received a great impetus in this country in consequence of the war and the necessary and unusual development of certain of our industries. Other features will be a report of the Aims and Organization Committee whose work is attracting widespread attention among the Sections of the Society, and a session conducted by the Detroit Local Committee and the Committees of the various Mid-Western Sections.

One session will be devoted to a survey of industrial relations, taking up certain aspects of labor conditions and covering employees' service. At least two sessions will be devoted to general technical papers. Particulars about excursions and social features cannot at this time be given, but it is needless to say that the wonderful resources of Detroit will be at the disposal of the members and their friends who attend the meeting.

Don't forget the Spring Meeting—June 16 to 19—when so many matters of vital interest to the profession and to the members individually will be discussed at this critical time in our history. Note that the meeting opens on *Monday*, June 16, instead of Tuesday, as has been usual.

Secretary's Letter

THE outstanding note throughout the country in this present period of uncertainty and unrest is that of optimism. During an extended trip among the Sections of the A. S. M. E., which has just been concluded, I have followed a path through the Central States to Chicago, then through the South Atlantic States and west to Oklahoma and up to the northern border. Everywhere this feeling of optimism is evident. I have yet to find one man, engineer or man of business, who does not think the cycle of temporary business depression will be completed during this calendar year; the majority say in six months, and not a few predict a shortage of labor within three months. I have been informed of contracts actually let for large increases in plants of certain industries, to be begun as soon as weather permits.

This condition in business obviously is reflected in the outlook for the work of the societies, local and national. I mention local first because I am unreservedly for developing and supporting the local society first of all. After one has done his full duty locally then he may join that national society which best serves his specialty.

Further, all local societies can depend on the support of our national organizations in charging the members to bear their full share of the work of maintaining professional interest in their communities. The best means for effecting such coöperation is for our Sections, and the sections of all the other national societies, to head up in the local society. As soon as this is accomplished in every locality we will have a truly national spirit and a community of interest.

The usefulness of the local organizations in public affairs is illustrated by action taken recently by the Associated Engineering Societies of St. Louis under the auspices of the Engineers' Club with reference to the proposed municipal bond issue of that city. Most of this bond issue is for engineering projects and consequently the engineer-citizen is vitally interested. At a meeting held to discuss the subject the civic committee of the Engineers'

Club participated, and there was very evident interest on the part of all in attendance.

The one great necessity in the industrial prosperity of the nation is research and more research. Indeed, if we are even to survive, much less excel, in the competition which is to come, we must reduce the unit cost to manufacture, and one of the potent means of doing this is to conduct adequate researches. For example, with the high wages and low efficiency of the present time, and with ships costing from two and a half to three times what other countries are paying, how can we endure unless we develop processes which will insure quantity production?

This work is peculiarly within the province of the engineer, and there is no more important undertaking under way by the different professional societies than that of their research committees. The development of the research attitude of mind throughout the nation should command our instant attention, and the desirability of a research department in every industry may well be emphasized.

This work must be done today. Tomorrow will be too late. The A. S. M. E., through its Research Committee, stands ready not only to act as a clearing house, but to take the initiative and, modestly at first, but nevertheless definitely, to make grants for promising research, when such is for the common good.

The National Research Council is to head up all the research work in the nation, and this Society is working hand in glove with the National Research Council in that field which is peculiarly ours.

An important adjunct in his work, in fact its predecessor, is our Library Service. Our joint libraries, comprising the best collection of technical books and periodicals on this continent, is literally "at your service." It has a large staff of trained searchers. It has been found that 40 per cent of all problems have already been solved by some one. Save time and money. Consult *your* library.

In this connection, I wish to congratulate the American Society of Heating and Ventilating Engineers for its vision and enterprise in undertaking research as a Society. Its plan contemplates the collection of a fund of $20,000 a year for five years to carry on this work.

Hand in hand with research is standardization. Our newly formed American Engineering Standards Committee, representing the several departments of the Government and the leading engineering societies, and paralleling the organization of the British Engineering Standards Association, bids fair soon to play its important rôle. Our Society has appointed as one of its representatives on the American Engineering Standards Committee the Canadian representative of the British Engineering Standardization Association, who is a member of our Society, to assure ourselves of the most complete coöperation.

Looking out into a still broader field we find that through the selection of a Washington representative by the Engineering Council (representing the societies in their relations with the public) we are fast taking on activities closely related to the life of the nation.

Another joint activity of the societies, operating under the auspices of the Engineering Council, is the Engineering Societies Employment Bureau. This service is just now in great demand—150 professional men daily seeking positions. In order that we may function more effectively in this activity, we need branches of this Bureau in each city. Will you assist?

Calvin W. Rice,
Secretary.

Council Meeting, February 22

A regular meeting of the Council was held in Pittsburgh, Pa., on February 22. On the morning of the day of the meeting an inspection trip was made to Dr. John A. Brashear's observatory and shops, which was followed by luncheon at the Duquesne Club. The Council meeting was held at 2:00 p. m. in the rooms of the Engineers' Society of Western Pennsylvania. An account of the business transacted at this meeting will appear in the April issue of Mechanical Engineering.

In the evening a public dinner, preceded by an informal reception, was held at the William Penn Hotel, to which all members of the Society in Pittsburgh and vicinity were invited. Among the speakers were Dr. John A. Brashear, Past-President and Honorary Member, Am.Soc.M.E., President Mortimer E. Cooley and George H. Neilson, President of the Engineers' Society of Western Pennsylvania.

Washington Office Opened by Engineering Council

A National Service Committee has recently been organized by the Engineering Council, having for its general purpose to seek out public services which may be best performed by engineering societies and to offer the proper men for such services; to speak authoritatively for the Council before committees of Congress and Governmental departments; and to supply first-hand information to engineers and their organizations regarding pending legislation.

M. O. Leighton
Chairman National Service Committee, Engineering Council, and Manager of Washington Office

The chairman of the Committee is Marshall O. Leighton, consulting engineer, Washington, D. C., under whose direction a Washington office for the Council has been opened at 502 McLachlen Building, Tenth and G Streets. The personnel of the Committee is representative of engineers throughout the country and comprises, besides the Chairman, the following men: C. B. Burdick, Chicago; George F. Swain, Boston; Philip N. Moore, St. Louis; L. D. Ricketts, Warren, Ariz.; Andrew M. Hunt, San Francisco and New York; Andrew M. Lockett, New Orleans; W. C. L. Eglin, Philadelphia, and Bancroft Gherardi.

Mr. Leighton, the Chairman, was graduated from Massachusetts Institute of Technology and has been a practicing sanitary engineer and consulting expert. He was connected with the Government in the U. S. Geological Survey for about eleven years and has been engaged in various public works, such as river hydraulics, water power, sewerage pollution, etc.

Discharged Engineers of Public Service Commission, New York, Now Reinstated

At the January meeting of the New York Section, as reported in the February issue of Mechanical Engineering, Mr. Charles Whiting Baker, Mem.Am.Soc.M.E., called attention to the action of the Board of Estimate and Apportionment in New York City, in the abrupt dismissal of some 370 engineers of the Public Service Commission of the city. In consequence of this drastic action, the Engineering Council, representing the Civil, Mining, Mechanical and Electrical Engineers, arranged a hearing on the

afternoon of January 14 in the Engineering Societies Building, New York, at which various representatives of city departments and of associations interested were present.

It developed that the Board of Estimate and Apportionment had adopted in December what is called a "line budget" the provisions of which led to the discharge of the engineers, but against whom no charges were made. In view of the facts developed at the hearing and the very evident curtailment of construction and disruption of a highly organized staff which would occur if the order were allowed to stand, the Engineering Council passed the following resolution:

Resolved, that in view of the above facts, the Board of Estimate and Apportionment be urged to reconsider at once its action of December 30 and to make such appropriation as will enable the Public Service Commission to carry on with safety and economy the rapid completion of the subway work, and that the Board of Estimate should leave to the Public Service Commission, on which the law places the responsibility, the detailed apportionment of these funds in accordance with a practical schedule to be prepared by it and submitted to the Board of Estimate for its information.

It is a pleasure to report that announcement was made on January 31 that the discharged employees had been reinstated, an appropriation having been made at the instance of the Board of Estimate and Apportionment sufficient to maintain the organization for the months of February and March.

Educational Work of Our Army Abroad

A great deal of interest is evidenced, both among engineers and educators, in the remarkable educational work of the A. E. F. abroad. This work has been developed under the efficient management of the Army Educational Commission of the Y. M. C. A., which has the direction of the courses of study and the selection of the personnel of the instructing staff.

The administration of the work, in so far as it is necessary for the Army to coöperate with the Commission of the Y. M. C. A. for its effective handling, is in charge of the General Headquarters abroad. General Robert I. Rees, who was recently Chairman of the Committee on Education and Special Training of the War Department, is now overseas in charge of arrangements for the military coöperation.

The work of the Army Educational Commission of the Y. M. C. A. in this country is directed by Dr. James Sullivan of the Department of Education of New York State; and by Samuel C. Fairley, Associate Home Director. Abroad, the work is directed by a Commission consisting of Dr. John Erskin, of Columbia University, *Chairman;* Dr. Frank E. Spaulding, Superintendent of Schools of Cleveland, Ohio; and Kenyon L. Butterfield, President of the Massachusetts Agricultural College.

Instruction is to be given at the various camps and at certain of the schools and colleges. The soldiers are to have the option of either five hours' drill or two hours' drill and three hours' educational work per day. Already 18,000 men are taking courses in the various departments. An idea of the extent of the project are expected to take courses of three months' duration in higher subjects at the various universities and colleges of France and Great Britain.

It is expected that at least half of the educational work will be of the vocational type, which is under the direction of Dean L. E. Reber, Mem.Am.Soc.M.E., of the University of Wisconsin, who has lately been in war work with the Emergency Fleet Corporation in Philadelphia. Assisting him are Dean W. H. Kenerson, Mem.Am.Soc.M.E., of Brown University; Prof. Frank C. Theissen, of the University of Wisconsin; Prof. E. R. Hedrick, Mem. Am.Soc.M.E., of the University of Missouri, and a number of other specialists.

The Y. M. C. A. has been conducting a recruiting campaign to secure educational executives, and as a result of its efforts more than two hundred men have sailed and one hundred and fifty are ready for sailing. A million and a half of textbooks and pamphlets valued at one and a quarter million dollars have been shipped already by the Y. M. C. A. for distribution among the soldiers.

Engineering Council Acts on Public-Works Control

A joint meeting of the Reconstruction, Public Affairs and National Service Committees of the Engineering Council was held on January 28 to consider what action should be taken relative to legislation affecting the supervision of national public works. The importance of the matter is evident from the fact that the value of construction work undertaken for the war, in the way of docks, hospitals, storehouses, railroads, water-supply systems, etc., aggregated $800,000,000 and that *every year* many million dollars' worth of engineering works are constructed, operated and maintained by the numerous bureaus and departments of the Government.

The war work mentioned has been carried on under the direction of the Construction Division, reporting directly to the General Staff of the Army. This division was recruited largely from engineers in civil life, 90 per cent of whom probably went into the work at a personal sacrifice. The law is such that 90 days after peace is declared the Construction Division must go out of existence.

One item of legislation referred to is an amendment of the Military Appropriation Bill providing for the continuance of the Construction Division and its permanent establishment as the Construction Corps, to have charge of the property which it has constructed, including completion, operation, maintenance and demolition.

Another item is the Kenyon Bill, S. 5397, which would create an Emergency Public Works Board "to coöperate with all federal, state and municipal agencies entrusted with the execution of public works, and to stabilize industrial and employment conditions during the period of demobilization." The bill carries a special appropriation of $100,000,000 and provides for further advances by the War Finance Corporation not to exceed an aggregate of $300,000,000 under the terms stipulated in detail and under control of the Secretary of Labor in conjunction with the Emergency Public Works Board. This bill as originally drafted gives the Engineer Corps of the U. S. Army a large measure of control in the civilian works to be constructed under the terms of the act.

It was the sense of the conference of the committees of Engineering Council that the legislation providing for the Construction Corps should be supported, but that the Kenyon Bill should be materially modified before its passage could be supported by engineers.

From Col. Elliott H. Whitlock

Col. Elliott H. Whitlock, former member of the Council of the A. S. M. E., writes from Toul, France, under date of December 27, 1918, as follows:

Soon after the first of October I was relieved from my work at the Engineering Depot at Is-sur-Tille and sent to the Second Army to join my regiment at Toul. I found our Colonel here in the Chief's office as Executive Officer and I was made Supply Officer for the army, with our regiment scattered all about the front, in charge of the depots and parks and also doing a lot of shop work.

We soon got some more machinery up here and put up a couple of good-sized shops where we could handle pretty good-sized jobs, machine, carpenter and blacksmith. I usually spent one day in the office and the next going out around the different places.

We got our engineering materials out in large quantities and placed well up to the front ready for the drive that started on November 10, so we were all ready to go forward; and then the armistice was signed on the eleventh and fighting stopped at eleven o'clock on that morning, and now we are hauling all that stuff back to the depots.

Part of our regiment were transferred to the Third Army, known as the Army of Occupation, and we soon started for Germany. That was a very interesting trip, for we passed over the old front lines of both sides and on up into Luxemburg and then across to Prussia. It was a grand sight to see the American troops by the thousands marching across the Moselle River bridges

into the enemy territory that Sunday morning, and an inspiring one, especially to those of us who had been so closely in touch with things for the past few months.

And now our regiment is all back here with the Second Army again, helping straighten out things and get the materials together, and the machines brought back to the depots so it will be in good shape to move; and what is more, we do not care how soon this is finished and the word comes to get ready to go home, for there is not a one of us but is anxious to shake this country and set foot on good old U. S. A. soil again. And I guess the most of us will agree with the fellow who, after landing in N. Y., said, "The Statue of Liberty will have to turn around if she ever wants to look me in the face again."

Request for Correct Addresses

The names listed below are those of members of the Society whose addresses are either unknown or upon which there is doubt. The Secretary will be pleased to receive information regarding the present addresses of these members.

Address Unknown

Barry, John L.
I. C. Green.
Robert M. Hale.
J. J. de Kinder.
James L. Kirsch.
Samuel F. McIntosh.
George P. Marrow.
Sir Charles H. A. F. L. Ross.

Address Doubtful

Chalmers B. Boles, c/o Wilson & Co., 71st St. and Ashland Ave., Chicago, Ill.
Capt. George S. Brady, 613 G St., N. W., Washington, D. C.
Lieut. Col. H. M. Byllesby, 1607 H St., N. W., Washington, D. C.
William W. Chace, Amesbury Apt., 18103 Canterbury Rd., Cleveland, O.
David P. Clemmer, U. S. S. B., 72 W. Adams St., Chicago, Ill.
Benjamin J. Cline, c/o Holt Mfg. Co., Peoria, Ill.
William H. Doron, c/o The Barrett Co., 17 Battery Pl., New York, N. Y.
Hugh H. Hargrave, 2238 Cecil Ave., Baltimore, Md.
First Lieut. William Knight, 509 W. 174th St., New York, N. Y.
Ragnvald Naess, Philippine Vegetable Oil Co., Inc., 608 Fife Bldg., San Francisco, Cal.
Capt. Burritt A. Parks, 509 Grand Rapids Saving Bldg., Grand Rapids, Mich.
Harold D. Root, 277 N. 20th St., East Orange, N. J.
Herbert S. Selindh, Holly Sugar Corpn., Swink, Colo.
Capt. Alexander C. Sladky, 892 14th St., Milwaukee, Wis.
E. Platt Stratton, 80 Broad St., New York, N. Y.
Capt. John Weber, 4413 15th St., N. W., Washington, D. C.
James J. Zimmerman, 313 South St., Johnstown, Pa.

Prize Essay Contest in Industrial Economics

The National Industrial Conference Board, Magnus W. Alexander, Mem.Am.Soc.M.E., Managing Director, offers a prize of one thousand dollars for the best monograph on any one of the following subjects:

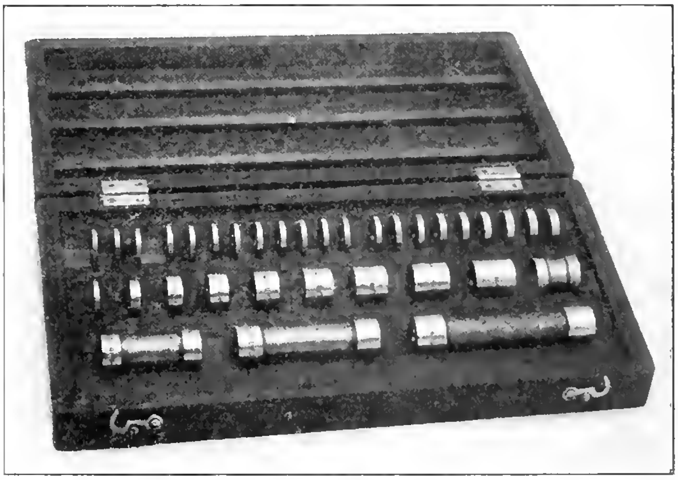
1 A practicable plan for representation of workers in determining conditions of work and for prevention of industrial disputes.
2 The major causes of unemployment and how to minimize them.
3 How can efficiency of workers be so increased as to make high wage rates economically practicable?
4 Should the State interfere in the determination of wage rates?
5 Should rates of wages be definitely based on the cost of living?
6 How can present systems of wage payments be so perfected and supplemented as to be most conducive to individual efficiency and to the contentment of workers?
7 The closed union shop *versus* the open shop: their social and economic value compared.
8 Should trade unions and employers' associations be made legally responsible?

The Committee of Award is composed of Frederick P. Fish, Chairman of the National Industrial Conference Board; Dr. Jacob Gould Schurman; Henry R. Towne, Past-President, Am.Soc.M.E.

Manuscripts, to be considered in the contest, must be mailed on or before July 1, 1919, to the National Industrial Conference Board, 15 Beacon Street, Boston, Mass., marked "For Prize Essay Contest in Industrial Economics."

Manufacture of Precision Gage Blocks at the Bureau of Standards

During the annual meeting of the A.S.M.E. in December, 1918, the demonstration conducted in the Branch Gage Section of the Bureau of Standards, in the Engineering Societies Building, New York, showing the utility of the light-wave interference method for measuring the precision gage blocks being made at the Bureau of Standards, attracted the attention of many members of the Society. The unheard-of accuracy with which these blocks were being produced, and the accuracy and facility with which comparisons of length, tests of flatness and parallelism were made by the interference method, resulted in many comments upon the method both as being novel and of particular interest.



Set of Gage Blocks Made by the Bureau of Standards

It is possible to produce these commercially to the remarkable accuracy of five millionths of an inch for length, flatness and parallelism through the use of the light-wave interference method of measurement

At that time there were exhibited several different sizes of precision gages which had been completed by the Bureau. Those who were fortunate enough to visit the Branch Laboratory will recall that the blocks produced are of a cylindrical shape rather than a prismatic shape, as are the similar Swedish gages. The blocks are made cylindrical rather than prismatic for the reason that greater wearing surface is secured, additional applications for direct measurement are possible, and the cylindrical shape is more economically manufactured.

There is shown in the accompanying illustration one of several sets of the cylindrical blocks which have been completed by the Bureau of Standards. The various blocks of these sets are being produced commercially to within an accuracy of 0.000005 in. for length, flatness and parallelism of the end surfaces. It has been found comparatively easy to hold the flatness and parallelism of the blocks to within about two millionths of an inch; and with special care absolute length may be held within this accuracy. However, for commercial sets the limit of five millionths of an inch mentioned above is deemed satisfactory.

The manufacture of these precision gage blocks is being carried out by the Gage Section, Bureau of Standards, in collaboration with the Engineering Division, Ordnance Department, U. S. A. When it is considered that there has been developed in a period of about six months the art of making gage blocks more accurate than those heretofore obtainable only in Sweden, where the manufacture has been carried on for 10 or 15 years as a secret process, the achievement represented in the development of the process for manufacturing these gages commercially will be realized.

The success in the development of the manufacture of the precision gage blocks on a commercial basis has been due largely to the efforts of Mr. H. L. Van Keuren, Mem.Am.Soc.M.E., Chief of the Gage Section, Bureau of Standards; Lieut.-Col. E. C. Peck, Head of the Gage Section, Engineering Division, Ordnance Department; and the inventor, Major William E. Hoke, Gage Section, Engineering Division, Ordnance Department. In addition, the facilities of the Optical Division and Metallurgical Division of the Bureau of Standards, and the full coöperation extended by Dr. S. W. Stratton, Director of the Bureau of Standards, has made it possible to realize a very rapid progress in overcoming unforeseen obstacles and securing blocks extremely accurate in flatness, parallelism and length.

Machine-Gun Cooling Problem

The Inventions Section of the General Staff is desirous of obtaining a solution of the problem of improving the methods of cooling machine guns during continuous fire, and the prevention of the freezing of the cooling liquid during cold weather when the gun is not in use.

At present the ordinary water-cooling system is used. It is necessary to transport several boxes of water for each gun in the field, as the water in the cooling jacket quickly turns into steam during firing. The following points should be observed in the solution of this problem:

1 It should be easily obtainable
2 It should be easily carried
3 It must not be too expensive
4 It must not injure the metal parts of the gun
5 If possible, it should be capable of being used several times so as to avoid extra weight
6 A minimum of waste during use should be obtained.

It must not be assumed from the above that a cooling system for machine guns must necessarily follow the lines of the present water-filled jacket. Any efficient method of cooling will receive serious consideration.

Correspondence in regard to this matter should be addressed to the Inventions Section, General Staff, Army War College.

The Relation of an Engineering Society to the Training of Workers

Two letters of general interest to engineers have been received by Mr. L. C. Marburg, chairman of the Committee on Aims and Organization, relating to the present and future need for the training of industrial workers. That this is one of the greatest of industrial problems cannot be doubted, and it is contended by each of the writers that it should come within the aims and purposes of the "Society of the Industries." We are informed by Mr. Marburg that, as a matter of fact, his committee expects to take up the subject of better training for industrial workers under heading A5 of the program entitled Education and Special Training. Quotations from the two letters follow:

U. S. DEPARTMENT OF LABOR
Washington, D. C.

I regret that you have not included in the outline of professional aims a paragraph relating to better training for industrial workers. Of what value are the most excellently conceived plans if there are not at hand men or women trained and sufficiently skilled to understand those plans, to appreciate their value and to execute them with efficiency and economy? As all students of development understand, this country has drifted into the habit of expecting to recruit its skilled labor from other lands and has not in any adequate manner made provision for replenishment of its supply of skilled workers. The rising wage scales and habits of other lands have dried up the stream of skilled labor supply. Even before the war broke out practically no skilled labor was coming to America. Now we cannot expect that any will come for several years, and unless American industries set out with deliberate purpose and broad understanding to inculcate training, we may find ourselves some fine morning with work to execute and nobody to do it.

This is an engineer's job if I ever saw one; and only engineers with professional ethics, with a broad point of view, with cultivated understanding, can save the situation.

C. T. Clayton,
Director.

UNITED STATES SHIPPING BOARD
New York City

This seems to be a subject which should receive a great deal of attention from the A.S.M.E. There are, I believe, four distinct branches in which the Society could very profitably interest itself, and for which there is a distinct need for definite consideration on the part of a representative body:

1 Legislation for regulating the conducting of training work in factories, whereby it shall be kept up to certain standards and conducted on certain systematic and thoroughgoing principles, possibly first considering the actual need of men required in the industry in order that clashes may be avoided with organized labor.
2 Preparation of material for the conducting of this work.
3 In connection with No. 1 the determination and promotion of standard methods and utilization of qualified instructors.
4 Organization of instructors and directors of training committees.

In this connection may I point out that the work of the United States Shipping Board in education and special training has been confined mostly to the training of men to increase and cheapen production.[1] This has resolved itself into three definite branches of work:

1 The training of tradesmen, utilizing these men as instructors and giving to them the necessary instruction in order that they may become capable teachers. The one great weakness in any training scheme heretofore has been due to the fact that the ordinary tradesman is anything but a good teacher.
2 The training of foremen, particular stress being laid on the handling of men.
3 The giving of supplementary courses in evening schools and other public institutions, the information given being very closely tied up with the work done by the men in the yards.

The foregoing, of course, involved the utilization of a large number of men who were already trade teachers and the getting out of a large amount of instructional material. A few figures will enable one to gage more definitely the amount of work that has been accomplished in this district alone in connection with the shipbuilding program: Twenty staff instructors have been utilized (for training the skilled shipyard men to become instructors); 390 tradesmen have been trained as instructors; 500 foremen have received foremen training courses; 3000 students have received supplementary training in evening schools, and 15,000 men have been broken in as shipyard tradesmen by the organized training methods of the Fleet Corporation.

R. V. Rickford,
District Representative, Education and Training Section.

The Bureau of Standards Gage Laboratories

THE Gage Section of the Bureau of Standards has become known to a large number of American manufacturers who required limit gages in the production of interchangeable parts for munitions of war. There has been developed at the bureau an adequate organization, and the apparatus, equipment and methods in use are such as to permit the accurate and quick testing of various types of gages, including screw-thread plug and ring gages, profile gages and plain gages, as well as precision standards, measuring tools and apparatus.

In addition to the Gage Section at Washington, branch gage sections have been established in the Engineering Societies Building, 29 West 39th Street, New York City, in the Plymouth Building, 22nd and Prospect Avenue, Cleveland, Ohio, and in the Meigs Building, Bridgeport, Conn.

Up to the present time the gages tested by the Bureau have been either for departments of the Federal Government, or manufacturing concerns who were executing war contracts. In the last few weeks, however, quite a number of gages have been submitted by manufacturing concerns engaged in peace-time production. It is the desire of the Bureau to meet this situation as it is felt that the organization and apparatus developed for war purposes should be maintained for the benefit of manufacturers during peace times. The future possibilities of this work, however, depend entirely upon the coöperation secured from manufacturers. The future possibilities of this work depend entirely, however, upon the coöperation secured from manufacturers.

Work of the Technical Staff

In connection with the work of the technical staff there has been accumulated a vast amount of information and data on the

[1] Some interesting pictures and a somewhat more detailed account of the work are given in *International Marine Engineering*, January 1919.

construction, measurement and use of all kinds of gages, and it is planned to use the technical staff now available for the preparation of pamphlets, publications and other literature in order to make this information accessible to American manufacturers. Furthermore, the technical staff will be engaged in research work: on steel treatment and methods used in the manufacture of gages; in developing, perfecting, designing and constructing simple forms of measuring instruments for shop use; and in arranging formulæ, charts and methods of computation in simplified form for the use of toolmakers and gage makers.

For the work of the technical staff, as outlined above, where the results are of general utility to American manufacturers, no charge will be made for the service rendered.

Schedule of Fees for Gage Testing

A nominal fee will be charged, however, for the routine test of gages when the results of the test will be of benefit to but one or two parties. The amount of this fee will depend largely on whether the gage is one that is easily measured, or is a complicated gage requiring the expenditure of considerable effort in its test. The fee will be based upon the accuracy of the test desired. The following schedule of fees is proposed:

Plain plug gages	$0.50 each
Plain ring gages	0.50 each
Snap gages	0.50 each
Flat or round-end standards or checks	0.50 each
Measurement of any one element, such as lead, angle, or diameter, of threaded plug gages	0.50 each
Measurement of lead or angle of threaded ring gages	0.50 each
Complete measurements of thread gages	1.00 each
Photographs of form of thread of threaded plug or threaded ring gages	0.25 each
Profile gages or fixtures	1.00 and up

(Depending upon the complexity.)

Such gages, instruments or tools as may be submitted for test should be accompanied with drawings or specifications with which they are supposed to conform in order to facilitate the test and to permit the reporting of the important dimensions of the gage submitted. Also, complete information should be included as to the route of the shipment of gages, the nature of the test desired, and the disposal of the gages after test.

Gage Shop

A gage shop was organized at the Bureau of Standards in Washington for the salvage of master gages and for the manufacture of master and inspection gages which were needed by the War Department for exigency purposes; such as to prevent stoppage of production, or for immediate use overseas. This shop, while not large, is equipped to manufacture all types of precision gages including precision end standards, profile gages, plug, snap and ring gages, and threaded plug and ring gages.

It is planned that this shop be used for the manufacture of such standard gages as may be required for certain apparatus, such as complete sets of standards for the use of the Government and American manufacturers, like those designated by the National Screw Thread Commission. These standards will be deposited in Washington, and possibly extra sets will be available at the branch laboratories for use in connection with problems or disputes arising among manufacturers. It is proposed, also, that this shop be utilized for the building of gages for manufacturers when the need is very urgent.

Manufacturers are urged to utilize the facilities of the Gage Section to the fullest extent in connection with their manufacturing work. In order that suitable arrangements can be made to handle promptly the routine work of gage testing, it is requested that the Bureau of Standards be advised now of the desire of manufacturers to submit gages for test and to utilize the other facilities available, and, also, that they notify the Bureau as to the approximate number of gages that they may wish to submit during the coming year.

United Engineering Society

Annual Report of President

During 1918 the activities of the United Engineering Society, the Library, the Engineering Foundation and Engineering Council were deeply affected by the German war and much important war work has been done in our building.

The endowment of Engineering Foundation was increased to $300,000 by an additional gift of $100,000 from Ambrose Swasey.

By bequest of Dr. James Douglas the American Institute of Mining Engineers received an endowment of $100,000, the income of which will be expended in the maintenance of its library (now a part of the joint library).

The Library has continued to grow and improve and now contains over 153,000 books and pamphlets. The Library Service Bureau has gained steadily. Its business for 1918 amounted to nearly $10,000.

Indexing of current engineering literature has been undertaken in conjunction with the Founder Societies and the Index is being printed in their publications. This service has been extended to the Engineering Institute of Canada and the Canadian Mining Institute. The expense is borne by the Societies. In this connection The American Society of Mechanical Engineers has purchased the Engineering Index heretofore published by *Industrial Management*.

In June the Westinghouse and General Electric companies donated to the United Engineering Society their Patent Control Library of about 8000 volumes. Other noteworthy gifts were a collection of 370 pieces relating to patent litigations, from Jesse M. Smith, and Dr. William Paul Gerhard's collection on gas engineering, transferred by the American Gas Association.

For lack of means the combined libraries of the Founder Societies have never been recatalogued as one library. The Library Board has just voted to undertake at once the complete recataloging of the Library. This work is estimated to cost from $20,000 to $25,000, and to require about two years. United Engineering Society can finance the project if the four Founder Societies are willing to contribute $2500 each per year until the work is done.

War conditions continued to interfere with the receipt of foreign publications throughout the year. Details of the Library's work for the year are recorded in the annual report of the Library Board. [See Mechanical Engineering, February, 1919, p. 183.—Ed.]

The membership of Engineering Foundation Board was increased in April from eleven to sixteen and an executive committee of five members was provided.

The following matters have been considered by Engineering Foundation:

There has been continued coöperation with the National Research Council;

Information collected about industrial laboratories in this country;
Continued investigation of the wear of gears;
Investigation of spray camouflage for vessels;
Investigation of secret selective control of wireless communication;
Investigation of weirs for measurement of water.

The foundation offered to make a survey of existing engineering societies and to formulate recommendations regarding coöperation, but the suggestion was not accepted by the Founder Societies.

The annual report of the Foundation shows income for 1918 $10,929.67, expenditure $7,490.76, and accumulated unexpended income $30,253.88. Its income is now $15,000 a year.

On May 2 a dinner was given at the Engineers' Club to Dr. George E. Hale, Chairman, and other representatives of National Research Council, by the officers of the Founder Societies, and a large meeting was held in the Auditorium on May 28 at which an address was made by Dr. Hale.

A joint meeting of United Engineering Society and Engineering Foundation Board was held October 7 to receive Mr. Swasey's additional gift of $100,000. This fund is in the form of securities and is deposited with the Cleveland Trust Company, of Cleveland, Ohio. November 14 a dinner was given to Mr. Swasey at the Engineers' Club, to which were invited the governing bodies of the four Founder Societies, the Engineering Foundation Board, the Library Board, Engineering Council and officers of the Club; seventy-two were present, including twenty-one presidents and past-presidents of the Founder Societies.

An oil portrait of Ambrose Swasey, painted by Weerts, of Paris, was presented by him to United Engineering Society and has been hung in the Library along with the portrait of Dr. James Douglas.

Engineering Council has devoted much of its energy to war work. The Council's work has been done through its general meetings, many committees and its secretary's office.

The committee called "American Engineering Service" was succeeded in November by Engineering Societies' Employment Bureau. It collected personal information about many thousands of engineers and filled many requisitions from various governmental departments, supplying the names of engineers carefully selected in each case. In addition, many engineers and vacant positions in civil life were brought together. The secretaries of the Founder Societies constitute the Board of Directors of this Employment Bureau.

The War Committee of Technical Societies devoted itself largely to reviewing thousands of inventions and suggestions for war work.

It was associated with the Naval Consulting Board. The Committee was discontinued in December.

Other committees appointed by Engineering Council have been the:

Fuel Conservation Committee
Public Affairs Committee
Patents Committee
Water Conservation Committee
License Committee
National Service Committee.

The Engineering Council has established an office in Washington, D. C.

Invitations have been extended to three additional societies to have membership and representation in Engineering Council.

The John Fritz Medal Board of Award, composed of representatives chosen by the Board of Directors of the four Founder Societies, awarded the medal for 1918 to J. Waldo Smith, "For achievement as engineer in providing the City of New York with a supply of water." The medal was presented before a large audience in the Auditorium on April 17.

The Engineering Societies Building has been fully occupied throughout the year. There are several applications for increased space, as well as applications from societies not now represented in the building. During the year the gratuitous use of the auditorium and meeting rooms was granted for various war purposes on twenty-two occasions. The taxes assessed upon portions of the building have been reimbursed by the six taxable societies. A change has been made in the superintendent, also the bookkeeper, resulting in economy and better efficiency.

The Society responded to the requests of the Fuel Administration for heatless Mondays and complied with the requests of the Board of Health of New York as to office hours during the influenza epidemic.

Four men who contributed largely of service or means to United Engineering Society have died since the last annual meeting: Dr. Frederick R. Hutton, Robert M. Dixon, Dr. James Douglas and Dr. Rossiter W. Raymond.

At this date the membership of the four Founder Societies is 36,000, and of associate societies 21,500, so that a total of 57,500 engineers now have headquarters in our building.

Funds for the benefit of Engineering Societies Library were obtained during 1918 from the following sources:

American Society of Civil Engineers	$4,000.00	
American Institute of Mining Engineers	4,000.00	
American Society of Mechanical Engineers	4,000.00	
American Institute of Electrical Engineers	4,000.00	
Income from Endowment Fund	5,000.00	
Total income		$21,000.00

Library expenses were as follows:

Salaries (except Service Bureau)	$15,137.59	
Books and binding	3,905.90	
Supplies and miscellaneous expenses	1,682.27	
Total		20,725.76
Unexpended balance		$ 274.24
Funds for the work of Engineering Council were provided by contributions of $4,000 each from the Societies of Civil, Mining, Mechanical and Electrical Engineers—Total.		$16,000.00

Engineering Council's expenditures were:

Secretary office	$6,368.85	
American Engineering Service and Employment Bureau	4,099.72	
National Service Committee	500.00	
War Committee of Technical Societies	2,257.68	
Traveling	363.54	
Total		13,589.79
Unexpended balance, December 31, 1918		$ 2,410.21

The income of the Society during 1918 was	$77,759.61
The expenditures totaled	72,342.28
Surplus for the year	$ 5,417.33
The surplus at the close of 1917 was	$ 8,116.10
The gain for 1918 has been	5,117.33
Total	$13,533.43
Amount now transferred to the Depreciation and Renewal Fund	8,000.00
Leaving the surplus December 31, 1918	$ 5,533.43

The General Reserve Fund established in 1915 remains at $10,000. The Depreciation and Renewal Fund is $86,163.78, the total of the two funds being $96,163.78.

The credits to the funds have been as follows:

	From General Funds	Interest
1907	$ 5,000.00	......
1908	5,000.00	......
1909	5,000.00	......
1910	5,000.00	......
1911	5,000.00	......
1912	5,000.00	......
1913	10,000.00	......
1914	20,000.00	1,441.39
1915	5,000.00	2,404.28
1916	10,000.00	2,610.45
1917	Nothing	3,581.29
1918	8,000.00	3,126.37
	$83,000.00	$13,163.78
	13,163.78	
	$96,163.78	

Beginning with 1915 the sum of $10,000 per year, plus interest earned, should have been added to the Depreciation and Renewal Fund in accordance with the action of the Trustees, November 19, 1914, or $40,000 for the four years of 1915, 1916, 1917 and 1918, but the income has not been sufficient and only $23,000 of the amount has thus been set aside.

The Funds held by the United Engineering Society December 31, 1918, were as follows:

Engineering Foundation Fund	$303,374.80
Library Endowment Fund	102,559.70
General Reserve Fund	10,000.00
Depreciation and Renewal Fund	86,163.78
Surplus	5,533.43
Total	$507,631.71

The real estate owned by United Engineering Society is valued at $1,947,171.16. The total net assets are $2,454,802.87.

The Finance Committee has very effectively supervised the accounts, the assessments, expenditures and the investments. Acknowledgements are also due the House Committee, composed of the secretaries of the Societies, for careful attention to the details of management of the building, and especially to Mr. Alfred D. Flinn, who has acceptably filled the post of joint secretary of the United Engineering Society, The Foundation and Engineering Council.

The affairs of the Society are believed to be in a satisfactory condition.

Charles F. Rand,
President, United Engineering Society.

FUEL PROBLEMS OF THE PACIFIC COAST

(Continued from page 269)

commercially practicable is compared with that of a high-grade compound locomotive working at maximum practicable steam pressures and superheat:

CENTRAL-STATION STEAM PLANT

Assumed steam pressure, lb. gage	300
Superheat, deg. fahr.	250
Vacuum (30 in. bar.), in.	28.5
Temperature of steam, deg. fahr.	672
Total heat above 32 deg. fahr. B.t.u.	1345.8
Available energy per lb. of steam, ft-lb.	340,500
Heat efficiency, per cent	33.8
Efficiency of turbine including generator losses, per cent	78
Efficiency of boilers, per cent	75
Thermal efficiency of turbo-generator: $33.8 \times 0.78 \times 0.75 =$	19.8
B.t.u. per kw-hr. at generator $= \frac{3412}{0.198} =$	17,230
B.t.u. per kw-hr. at switchboard allowing 2.5 per cent for auxiliaries, etc.	17,660
Assumed load factor, per cent	50
B.t.u. per kw-hr. output of plant at 50 per cent load factor	21,200
Lb. coal of 11,500 B t.u. per kw-hr. output of plant	1.84
Assume average percentage efficiencies of transmission and conversion from power house to drawbars of electric locomotive as follows:	
Step-up transformers 98.5	
Transmission line 95	
Step-down transformers 97.5	
Conversion apparatus 88	
Trolley distribution 90	
Locomotive 88	
Combined efficiency power house to locomotive drawbars 63.4	
B.t.u. per drawbar hp-hr. $= \frac{21,200}{0.634} \times 0.746 =$	25,000
Lb. coal of 11,500 B.t.u. per drawbar hp-hr. =	2.17

COMPOUND LOCOMOTIVE WITH SUPERHEATERS

Assumed steam pressure, lb. gage	225
Operating steam temperature, deg. fahr.	625
Superheat, deg. fahr.	227
Total heat above 32 deg. fahr., B.t.u.	1326.6
Available energy per lb. of steam, ft-lb.	184,500
Heat efficiency, per cent	18.5
Efficiency of engine (steam and mechanical), per cent	75
Efficiency of boilers, per cent	65
Efficiency from fuel to drawbar, per cent: $18.5 \times 0.75 \times 0.65 =$	9.02
B.t.u. per drawbar hp-hr. $= \frac{2550}{0.0902} =$	28,300
Assume load factor, per cent	25
B.t.u. per drawbar hp-hr. at 25 per cent load factor	46,000
Assume standby and other unavoidable abnormal losses, per cent	30
Total B.t.u. per drawbar hp-hr.	65,700
Lb. coal of 11,500 B.t.u. per drawbar hp-hr.	5.7

AMONG THE LOCAL SECTIONS

(The Usual Brief Accounts of the Sections' Meetings and Student Meetings Will Be Found in Section Two of MECHANICAL ENGINEERING.*)*

WE are just about in the middle of the active season for the Local Sections' work, and now is a good time to comment on how things are going and what are the prospects for accomplishing what we set out to do; what are the new tendencies and what will be the outcome at the end of the year.

Most of the Sections have now resumed their programs which were abruptly halted by the influenza epidemic, and some exceedingly interesting meetings are being held. For example, Cleveland carried out successfully on February 4 the first of its quarterly all-day conventions with the following program: 10:00 a. m., Rubber and Its Manufacture by Prof. H. E. Simmons, Akron; 11:00 a. m., Electric Traveling Crane Development (Illustrated) by G. W. Shem, Alliance Machine Co.; 12:30 p. m., luncheon served in C. E. S. rooms. Following this Colonel J. R. McQuigg gave an address on Some Experiences of Engineers in France. Automobiles were provided to take 250 guests and members to the new plant of the National Acme Company, which comprises over seven acres under one roof and an installation of the largest and most modern screw machines.

The party returned in time to arrive at the University Club where dinner was served at six o'clock. Dr. Charles S. Howe, President of Case School of Applied Science, was Toastmaster. Addresses were made by C. A. Otis of the War Industries Board and Major J. R. Campbell of the Ordnance Department on How the Big Guns Were Developed. Motion pictures taken at Aberdeen Proving Grounds were also exhibited. Over three hundred sat down to dinner.

Other meetings of unusual interest have been held at Boston and New York at which addresses were made by the representatives of the various societies who went abroad at the request of the engineers of France to confer on reconstruction problems. Accounts of these meetings are given elsewhere in this number.

Secretary Rice, at the time of writing, is on his second trip among the Sections and his experiences are being reported in another column. When he has completed this trip and also a third trip contemplated for the middle of March, he will have visited every Section as well as a number of places in which Sections are contemplated.

Mr. Ernest Hartford of the A.S.M.E. staff has been released by the War Department, and has now returned to his work in connection with Sections affairs. He has recently visited Cleveland, Akron, Erie, and Buffalo.

At the last meeting of the Meetings Committee a tentative program for the Spring Meeting was laid out and one of the professional sessions was assigned to the Mid-Western Sections for them to procure the papers; and the Chairman was instructed to visit Detroit and find out to what extent the suggestion could be put into effect. If it materializes that the Sections carry out this session, with the Detroit Section responsible for the entertainment of the whole convention, then the Sections will truly have played an important part in the Spring Meeting.

Coöperation with the Aims and Organization Committee should be pushed at this time. This Committee hopes to have a meeting about the end of March, and before long the Section delegates will take up with their respective Local Sections the matter of assigning a definite meeting to the discussion of this Committee's program. In the same connection, Local Committees should have received requests from delegates for the appointment of subcommittees in each Section to support these delegates; to date, about six Sections have made such appointments. This Committee's work is very urgent, as the field is enormous and the Committee has to make a report by the Spring Meeting.

Coöperation between the Increase in Membership Committee and the Local Sections has been initiated by the former Committee asking the Local Committees to what extent they have developed membership increase in their Sections. A number of helpful replies have been received and it is expected that the two major committees will shortly formulate a plan of coördination of activities.

An Unoccupied Rung in the Engineer's Ladder of Fame

DETROIT and the Detroit Section had the honor of being first to have an address from the new President of The American Society of Mechanical Engineers, Dean M. E. Cooley. President Cooley spoke at a special meeting of the Detroit Section held at the Board of Commerce on January 11.

He said that the Secretary at first asked him to make some informal remarks; but that later he had asked him to wire the title of his *address*. He had therefore spent a good part of one forenoon working up the title, and was so pleased with it that he wired it in immediately. But after he had sent the wire he had tried to think what he would say under the title. He told his audience that it was one of the finest titles he had ever worked out, and that some day he would write an address to go with it; but, nevertheless, the thought which he wished to bring to the meeting would work in with the title that he had decided upon, namely, An Unoccupied Rung in the Engineer's Ladder of Fame. Continuing, President Cooley said in part:

"It is unnecessary to point out to a body of engineers what engineers have accomplished in the development of the material part of the world's civilization. The entire world, so far as its material structure is concerned, can very justly be said to be the work of the engineer, or of professional men very closely allied to the engineer and to engineering. Our great buildings, our railways, the subways of New York City, would not be possible without the work of the engineer. But it is not necessary to enumerate such features. It is enough to say that it would be difficult to think of anything that makes it possible to live the life we are living—I am speaking, of course, of the material side—that was not conceived by the engineer.

"Then look at what has happened in our relations with different countries of the world through navigation on water and in the air, the latter developed to the most wonderful extent since the war began, and only in its infancy at the present moment. And look at the great conflict, with the result brought about by the work of the engineer—and the war itself brought about by the work of the engineer in the first place in helping to create commercial supremacy—fought and won by means designed and built by the engineer; and I think if the engineer had the settling of the war, it would be pretty well done; but it is going to be settled by other than engineers, and it won't stay settled, you can be sure of that. I don't want to speak in any pessimistic way at all, and I don't think I am so speaking when I say that it is in my bones that the war has just begun, absolutely just begun—that is a thought for you to carry away with you. Some of you will recall your study of history and the days of Augustus Cæsar, and following to the end of the decline of the Roman Empire, and at the beginning of the dark ages, when the Huns swept down and destroyed the civilization of the world. Who knows what the future has in store? Who can say that we are not going to have another dark age? I am not going to argue that we are at all—I just raise that question as something for you to think about. We are optimistic in this country. We are very optimistic with our opportunities in this country; we have no thought for the morrow except as we may make more than we made today.

"Now, all this leads around to the unoccupied rung I had in my mind.

"I have tried to show you that the engineer stands preeminent in the world today because of his work, upon which depends so much, the civilization in which we live, and because of which we have seen also the destruction in this war of civilization.

"Now, the engineer has done all these things in his professional capacity. We have wonderful experts. The different professions are filled with experts, men who know one thing and know it better than any other man in the world. It is natural that the engineer should become a specialist. It is the bread-and-butter thing for him to do. In doing this he is creating for himself a big reputation among his colleagues in engineering lines.

"But the engineering profession needs something more for itself, and the world needs something more from the engineer. The world needs the engineer with all his technical training to take a part in its general affairs, which up to now he has not taken. The engineer has not performed his duty to the general public. He has not given the general public the benefit of his knowledge which would enable many of the great questions which are puzzling the world today to be settled over night—if there was any desire to have them settled.

"Take your Detroit street-railway situation—you may not have heard of that. (Laughter.) It is as simple a problem as A, B, C; but does Detroit want it settled? What would be done for political capital if it were settled? *Quien sabe?* I am told that the same thing is true of Chicago. The engineer's job, as I see it in such a situation, is to make it known that problems like these can be settled if the people want them settled, and that the engineers know how to settle them.

"So the idea I had in mind in choosing this title that has been announced this evening, viz., this unoccupied rung in the engineer's ladder of fame, has to do with the engineer occupying positions in public relations which he has not up to now occupied.

"What is the best training for taking this position; going back to the college, for instance? I would say that the best training would be secured by first recasting the engineering curricula that we have. Leave out of them, at least, a quarter or half of the professional stuff that is now taught, and substitute for it the good old stuff that we used to have crammed down our throats when some of the older of us were boys or young men. I believe it to be a fact that the engineer who was graduated back in the 70's or 80's was a much more broadly educated man than the engineer who is graduated today. He was a better man to cope with the general problems that arose in the field of engineering, for the man graduated today can do only one thing, as a rule, while in those old days he could do a good many things well. While this may sound like heresy, I believe, nevertheless, that we should make our education more liberal. And if I can do one thing more before I finish my work at the University of Michigan, and one thing while I am president of The American Society of Mechanical Engineers, it will be to hammer on the one thought that we must break down the walls which we are building around the young men who are in college—walls built so high that they cannot look over. Break them down and use your influence to have them broken down. See that your boys, who are going to become engineers, are so trained that they do not have to remain privates or non-commissioned officers in an army of engineers but that they can be field officers, line officers, major-generals, lieutenant-generals of engineering, men who are qualified to be on the hilltop and look far away and have a proper perspective. That is what I mean by the unoccupied rung in the engineer's ladder of fame.

"Where do you find engineers occupying big public positions, political positions, if you like? But we do not like politics. How many engineers are there in Congress, how many in the cabinet? How many on the public-service commissions? Answer these questions and you will find where the unoccupied rung is. Perhaps we cannot do much in the little of life that is left to us, but certainly we can train those who follow us, and those who follow them. We should bring up in this country a different kind of engineer, a man who by his broad education and training will stand head and shoulders above the professional man of today. That is the kind of man I want to see, and you gentlemen can do it. My message to you tonight is to awake you to a sense of your responsibilities, not alone to your own profession but as an engineer and citizen to the public.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

THREE communications have been received in time for this number of MECHANICAL ENGINEERING which have been used in making up our notes for the current issue. Next month we hope to have many more. The success of the department depends on the coöperation of engineers who are engaged upon or are interested in research matters. Have you any data or inquiries to send in?

Information is desired relative to research work conducted by laboratories, either commercial or professional, by colleges, by Government institutions, or by individuals, and the Chairman would appreciate advice from any of these sources.

As outlined in the last number, the Research Committee hopes to conduct its department under the following heads:

A RESEARCH RESULTS
B RESEARCH IN PROGRESS
C RESEARCH PROBLEMS
D RESEARCH EQUIPMENT
E RESEARCH, PERSONAL NOTES
F BIBLIOGRAPHIES

The method of reporting work in these notes will be to give a title to research of a general nature followed by a serial number and the year. The special title will then be given. Reference by general title with numbers is all that is necessary. The name of the person is given from whom information may be had, together with the address.

ARTHUR M. GREENE, JR., *Chairman.*

B—RESEARCH IN PROGRESS

Metallurgy 2-19 Data on Influence of Size in Heat Treatment. (Research Committee of American Steel Treaters' Society.)

Metallurgy 3-19 Data on Critical Points. (Research Committee of American Steel Treaters' Society.)

Metallurgy 4-19 Statical Tests on Special Steels in Connection with Different Heat Treatments. (Research Committee of American Steel Treaters' Society.)

Metallurgy 5-19 Standard Heat Treatment of Gears, Shafting, etc., with Regard to Dimensions. (Research Committee of American Steel Treaters' Society.)

The above list represents the problems of a committee of a sister society and any data had by our members would be gladly received by their secretary, E. J. Janitzky, Metallurgical Engineer, Illinois Steel Co., So. Chicago, Ill.

Metallurgy 1-19 Bearing Metals. (Sub-Committee on Bearing Metals of the A.S.M.E., Christopher H. Bierbaum, *Chairman*, Buffalo, N. Y.)

Heat 1-19 Heat Transmission. Transmission of heat through various forms of partitions. (Sub-Committee on Heat Transmission, A.S.M.E. George A. Orrok, *Chairman*, 29 W. 39th St., New York.)

Lubrication 1-19 Lubrication. (Sub-Committee on Lubrication of the A.S.M.E. Albert Kingsbury, *Chairman*, Pittsburgh, Pa.)

Meters 1-19 Flow Meters for Fluids. (Sub-Committee on Flow Meters, A.S.M.E. R. J. S. Pigott, *Chairman*, 29 W. 39th St., New York.)

C—RESEARCH PROBLEMS

Gases 1-19 Critical Velocity for Gases. (Submitted by Strickland Kneass, Jr., Youngstown, Ohio.)

E—RESEARCH, PERSONAL NOTES

A visit to the Bureau of Standards at Washington, D. C., by the Chairman of the Research Committee of the A.S.M.E. was made on Feb. 10, 1919. The Director of the Bureau, Dr. S. W. Stratton, explained some of the work of the Bureau and made clear that the Bureau is prepared to give to manufacturers advice relating to fundamental facts and researches of physics, chemistry or any branch of science on which their special application may rest. This institution is organized to give aid to those requiring it if this aid is confined to the fundamental principles.

Friction 1-16 Friction and Allied Subjects.

Research in Heat Transmission

At the recent annual meeting of the American Society of Heating and Ventilating Engineers George A. Orrok, Mem.Am. Soc.M.E., made a plea for coördination in research in heat transmission. Mr. Orrok is chairman of the sub-committee of the Research Committee of the A. S. M. E. on the subject of heat transmission, the other members of which are Prof. A. T. Wood, Dr. Harvey N. Davis, Dr. Edgar Buckingham and Arthur D. Pratt. Mr. Orrok said in the course of his remarks before the H. and V. Engineers:

The exigencies of the war have precluded the chance for any but the merest beginnings of the work of this sub-committee, as most of its members have been actively engaged in governmental activities. Mr. Buckingham is still in Italy; Mr. Pratt has had his hands full with work for the Emergency Fleet Corporation; Professor Wood with the S. A. T. C., and Dr. Davis and I with the helium work. However, we have found time to organize and partition the preliminary work among the various activities best fitted to secure results. Professor Wood has enlisted the committee of the American Society of Refrigerating Engineers in what I might call, in default of a better word, the "Insulation Division," and we have asked your committee of the American Society of Heating and Ventilating Engineers to work with them and coöperate along these lines and also in the subject of building materials.

Work on the radiator problem is being considered by your society as well as the A.S.M.E., and we shall be able to organize and coördinate this very shortly, as well as the kindred but very different line, that of aeroplane and automobile radiators. The problem of heat transfer under steam-generating conditions is also being organized and work is being done.

In the condenser and heater field there is yet some unpublished work which will be made public shortly and there are certain physical discoveries to be digested and applied to results already obtained. This work will be undertaken very soon and will be available.

In numerous other lines work has been laid out, and as fast as the men return from the front to their ordinary lines we shall endeavor to have work started and carried on to a satisfactory end.

But the main work of the committee, the formulation of an adequate and universal law of the transmission of heat, is, I think, very far off in the future. Dr. Buckingham, I believe, has stated that in the simple problem of the transfer of heat from steam to water through a copper tube there are 26 quantities entering into the equation, most of which are partially unknown or rather imperfectly known.

In this connection it is well to recall the many experimenters in this field who have worked on the same identical problem with results as diverse as can well be imagined. The fault lay in the apparatus used which had not been arranged with a view to the elimination of the many unknown factors affecting the transmission of heat. Some of these researches are of value today now that we know how to apply the proper correction factors, but most of them represent wasted effort. Another class of investigations are of little or no value because only such heat was transmitted as was present in the apparatus, the result being, of course, limited to this amount. Another class of experiments must be considered as useless since the leakage condition was so bad that no consistent results could be obtained. Let us report all contemplated and undertaken research to the committee, ask advice and avoid duplication.

Research Work and New Equipment at Purdue University

Tractor-Testing Laboratory. Through the agency of the Engineering Experiment Station at Purdue University, Lafayette, Ind., a new farm-tractor-testing plant is being constructed. The plan is to test farm tractors the same way as the locomotive has been tested at the same institution.

The equipment will be placed in a laboratory newly constructed for that purpose, and will include electric dynamometers, specially designed recording transmission dynamometers, and other apparatus. It is hoped by this means to assist in standardizing the information which the buying public, as well as the people who are in the market for the farm tractor, desire to know. A description, with photographs showing the complete plant, will be forthcoming for MECHANICAL ENGINEERING in the weeks to follow.

Research Work. For a year and a half extensive work has been carried on at Purdue University along two distinct lines: One, under the direction of Professor Berry, in connection with the Engineering Experiment Station, takes up the carbonization of liquid fuels. Four phases of this research work are worth mentioning: The first is the volatilizing temperatures of liquid fuels as affected by a "hot spot"; second, the effect of efficiency on internal-combustion motors with the wet or dry mixture; third, the effect on efficiency and power capacity of preheating the air; and fourth, the effect on efficiency of raising the temperature of the mixture. A paper on some one of these phases will probably be prepared by Professor Berry for presentation at the Spring Meeting.

Another line of unusual interest being carried on at the University relates to the utilization of crushed coal in furnaces connected with power plants. In this connection the coal is not dried nor is the crushing carried to such an extent as to be in any way known as powdered fuel. Thirty per cent of the coal is about the size of a grain of wheat. Later on, when the results are completed, the whole story will be presented in a formal paper.

LIBERTY ENGINE TESTS

(*Continued from page 253*)

The mechanical adjustments when considered in connection with the motor inspection after test seemed to vary in proportion to the thoroughness of inspection between flights. Replacements which were made during the flight test all point to the same general kind of troubles in each case, and seem to be a true indication of the class of workmanship and inspection involved in the manufacture of these motors. It is quite probable, however, that many of the replacements made were not absolutely necessary for continual running, but they were considered essential for safety. (Bulletin, August 1918, p. 50.)

It may be added that the foregoing constitutes the first truly technical presentation of the achievement involved in the design and construction of the Liberty engine open to general engineering circles, and it is hoped it will help to dissipate the doubts and misunderstandings surrounding this subject. A general survey of these tests shows a careful and thorough effort to investigate all the elements contributing to the operation of the motor and a willingness to test the motor under strenuous conditions closely approaching those which it would meet at the front. Even though 160 hr. of continuous operation may not be sufficient to beat the average record of such an engine as the Rolls-Royce, it represents unquestionably a great achievement in view of the fact that the Liberty motor can be produced in quantity many scores of times greater than the Rolls-Royce could be produced under American conditions. Furthermore, for military use 125 to 160 hr. of useful life is fully adequate.

COMMITTEE ON AIMS AND ORGANIZATION

The question of national coöperation among engineers and the improvement of their position in the esteem of society, a question of first importance in ordinary times, has assumed even greater moment in the period of reconstruction following the war, and serious attempts are being made by all the national engineering societies to reduce this coöperation to a concrete form. The participation of The American Society of Mechanical Engineers in this movement is being engineered by the Committee on Aims and Organization, appointed

last December to "discuss and formulate the aims of the Society in the light of modern development and present-day thought, and to assist toward finding a method of coöperation with the rest of the engineering profession suitable to carry out the aims." The committee consists of one delegate from each of the local sections and seven members at large. It held a two-day meeting in connection with the Annual Meeting and plans to report to the Society at the forthcoming Spring Meeting, to be held in Detroit, Mich., June 16 to 19, 1919.

COMMITTEE ON AIMS AND ORGANIZATION

ON pages 296 and 297 are given photographs of members of the new special Committee on Aims and Organization which held a two-days' session at the Annual Meeting, and which will meet again and prepare a report of progress to be presented at the business meeting of the Spring Meeting. The program of this Committee has already been published in MECHANICAL ENGINEERING, as well as the statement of its chairman of the results of its first sessions. The following supplement to the photographs will be of interest:

LEON P. ALFORD, member at large and member of the Executive Committee, is editor of *Industrial Management* and is an authority in that field. He is a graduate of Worcester Polytechnic Institute and has had many years' experience with machinery-building firms and in engineering editorial work. He is the author of several engineering publications. He has been active in committee work in the Society and was last year chairman of the Committee on Meetings.

CHRISTOPHER H. BIERBAUM, representing the Buffalo Section, has for twenty years made a special study of bearings, and in recent years has made extended researches on graphite and its application to lubrication. He is now doing special research work in the microstructure and microcharacteristics of the bearing alloys. He is chairman of the Sub-Committee on Bearing Metals of the Research Committee.

L. P. BRECKENRIDGE, representing the Connecticut Section, is best known for his work on fuels. He has been a teacher of mechanical engineering since 1882—at Lehigh University eight years, Michigan Agricultural College two years, University of Illinois sixteen years and Yale University five years. He has been very active in the work of the Connecticut Section.

E. S. CARMAN, representing the Cleveland Section, of which he is chairman of the Executive Committee, has been since 1913 secretary and chief engineer of the Osborn Manufacturing Company, Cleveland. He has been active in engineering society affairs for several years past; and especially active as librarian of the Cleveland Engineering Society, in advocating a united engineering organization for all branches of the profession.

RALPH COLLAMORE, representing the Detroit Section, has been continuously connected with the firm of Smith, Hinchman & Grylls since 1903. He has been president of the Detroit Engineering Society, the Michigan Chapter of the American Society of Heating and Ventilating Engineers, etc., and was chairman of the Organization Committee of the Detroit Section. He is a member of the Committee for Revising Building Codes of the City of Detroit, and was recently chairman of the Local Advisory Committee of the U. S. Fuel Administration.

ALBERT GREENE DUNCAN, representing the Boston Section, has been treasurer of the Harmony Mills, Cohoes, N. Y., since 1910. He has been active in society affairs and was at one time president of the National Association of Cotton Manufacturers. During the war he was appointed on the Boston Advisory Committee for the Purchase of Army Supplies.

SUMNER BOYER ELY, member at large, was at one time chief engineer of the American Sheet Steel Company, and secretary of the Board of Engineers of the U. S. Steel Corporation. He is a member and past officer of the Engineers' Society of Western Pennsylvania, and for the past year has been president of the University Extension Society of Pittsburgh.

JOHN T. FAIG, representing the Cincinnati Section, has been active in society affairs. He has been three times president of the Engineers' Club of Cincinnati, and is vice-president of the Society for the Promotion of Engineering Education. He was for twelve years professor of mechanical engineering at the University of Cincinnati, and since 1918 has been president of the Ohio Mechanics' Institute.

HOWARD P. FAIRFIELD, representing the Worcester Section, is secretary of the Sub-Committee of Machine Shop Practice of the Committee on Meetings. Since 1899 he has been on the faculty of the Worcester Polytechnic Institute, and in 1914 was appointed assistant professor of machine construction.

HOWARD M. GASSMAN, representing the Birmingham Section, was at one time chief electrical engineer of the Tennessee Coal, Iron and Railroad Company. Since 1916 he has been engaged in general consulting work along power and industrial lines, with offices in Birmingham.

W. F. M. GOSS, member at large, past-president of the Society, is president of the Railway Car Manufacturers' Association. He came to this position in 1916, after having been for eleven years dean of the College of Engineering at the University of Illinois.

LEWIS GUSTAFSON, representing the St. Louis Section, is chairman of this Section for the current session. He has been superintendent of The David Ranken Jr. School of Mechanical Trades, of St. Louis, since 1907, and prior to that for several years was with the Lewis Institute of Chicago.

JAMES HARTNESS, member at large, and past-president of the Society, is known as an inventor and manufacturer of various machines for metal turning, designed to take the place of the engine lathe. He has been granted over one hundred patents in this field. He is president of the Jones and Lamson Machine Company of Springfield, Vt.

JOHN LOVEJOY HENNING, representing the New Orleans Section, has been for twenty years with the Union Sulphur Company, operating the Frasch process for sulphur mining. He is now vice-president of this company and in charge of all their interests in the South.

DEXTER S. KIMBALL, member at large, is the chairman of the Committee on Meetings and Programs of the Society. He has been professor of machine design and construction at Cornell University since 1904, and during the summer of last year was acting president of the university. He is the author of publications on machine design.

C. E. LORD, representing the Chicago Section, is in charge of all patent and trademark work of all the International Harvester Companies. He is a member of the bar of the states of Ohio, Wisconsin and Illinois, as well as a member of a number of engineering organizations.

FRED R. LOW, member at large, has been editor of *Power* since 1888, in which position he has won distinction not only for the publication itself, but as an authority on power-plant subjects. He has served on a number of committees of the Society. He is the author of textbooks on steam engines.

LLEWELLYN V. LUDY, representing the Indianapolis Section, and member of the Executive Committee, has been professor of experimental engineering at Purdue University since 1912. Previous to that he was professor of steam and gas engineering at the University of Wisconsin.

THOMAS C. MCBRIDE, representing the Philadelphia Section, has been engineer for the Worthington Pump and Machinery Corporation since 1899. He is a specialist in sugar refineries, sugar machinery and paper mills and machinery. He was chairman of the Philadelphia Section when first organized.

LOUIS C. MARBURG, member at large, was elected as chairman of the Committee on December 3, 1918, after having acted as temporary chairman in accordance with resolutions of the executive committee of the general committee. He has been secretary and treasurer of Marburg Brothers, Inc., engineers, since 1910, engaged mainly in the import and export of engineering products. Previous to that he was with the Allis-Chalmers Company, General Electric Company, Sprague Electric Company, Siemens and Halske, and Sulzer Brothers.

GEORGE KINGDON PARSONS, representing the New York Section, is also chairman of the War Industries Readjustment Committee. For several years he has specialized in reorganizing and improving established businesses, as president of the G. K. Parsons Corporation.

EARL F. SCOTT, representing the Atlanta Section, has for the past five years been engaged in business as agent and contracting

mechanical engineer. He is now president of the corporation which bears his name, engaged in selling and installing power-plant equipment.

C. M. Spalding, representing the Erie Section, has been for more than twenty years with the General Electric Company, engaged chiefly in engineering and design of railway motors, railway locomotives, air compressors and other allied apparatus for railway service.

Louis Edward Strothman, representing the Milwaukee Section, entered the employ of the Allis-Chalmers Company in 1902 and has held various positions. In 1915 he became manager of the steam-turbine and pumping-engine departments. He was chairman of the Milwaukee Section in 1915 and was president of the Engineering Society of Milwaukee the following year.

Charles W. Tubby, representing the Minnesota Section, has been in charge of the business of the Worthington Pump and Machinery Corporation since 1912 in the Middle Northwest and all of the Lake Superior mining regions. For six years previous to that he was in private business in St. Paul, representing builders of heavy machinery.

A. E. Walden, representing the Baltimore Section, has held responsible executive positions since 1891, including those of engineer in charge of construction, superintendent and manager of various companies, as well as construction and reconstruction of industrial and manufacturing plants, grain elevators, coal properties, transmission lines, etc.

John T. Whittlesey, representing the San Francisco Section, has since 1912 been retained to advise Messrs. Spreckels in their large public utilities interests in California. He was at one time chief engineer of the Brooklyn Rapid Transit Company, and also chief engineer of the Public Service Corporation of New Jersey.

Robert William Angus, representing the Ontario Section, was chairman of the Executive Committee of that Section last year. He has been professor of mechanical engineering on the faculty of applied science of the University of Toronto since 1906.

Charles H. Repath, representing the Los Angeles Section, was at one time mechanical superintendent of the Anaconda Cupper Mining Company, and later superintendent of the International Smelting and Refining Company. He is now in consulting practice in Los Angeles.

George I. Rockwood, member at large, and member of the Executive Committee, is a consulting engineer at Worcester, Mass. He is president and treasurer of the Rockwood Sprinkler Company. He was formerly on the publication committee of the Society and was chairman of the Worcester Section.

NEWS OF THE ENGINEERING SOCIETIES

Inspiring Address by Dr. Ira N. Hollis before Engineering Institute of Canada—Heating and Ventilating Engineers Start Research Work—Automotive Engineers Meet

The Cleveland Engineering Society issues a live weekly Bulletin called "Cleveland Engineering" which bears out the reputation of the Society for maintaining close contact with both the public and its membership. The issue of this Bulletin of January 7 contains a portrait of Major Frank B. Gilbreth, Mem.Am.Soc.M.E., who gave a talk before the society, illustrated by moving picture films of the Browning machine gun. It also reprints in full from Mechanical Engineering (January, 1919, page 16) the article by Jesse M. Smith, Past-President, Am.Soc.M.E., on a plan for the organization of engineers.

Akron Engineers Form New Club

The engineers of Akron, Ohio, and vicinity met on the evening of February 5 for the purpose of organizing an association of engineers at Akron. Dean F. E. Ayer, head of the department of engineering of the University of Akron, was elected chairman; M. B. Robinson, professor of mechanical engineering at the University and a member of the A.S.M.E., was elected secretary and treasurer, and an executive committee of 14 members representing different lines of technical work was chosen. The following sub-committees have been appointed: Organization, Program, House and Publicity. The initiation fee has been set at $5.00 and the dues at $3.00, and one hundred and eight applications for membership have already been received.

Mr. E. S. Carman, Chairman of the Cleveland Section of the A.S.M.E., was present and outlined the successful work along both civic and engineering lines which has been accomplished by the Cleveland Engineering Society.

The second meeting of the organization was held Wednesday evening, February 19, with a dinner, followed by an address by the county surveyor relative to existing and proposed engineering operations in the county. These operations are vital in a large degree to the city of Akron, its water supply, etc.

American Steel Treaters' Society

There has recently been organized in Chicago the American Steel Treaters' Society, whose object is "to promote the arts and sciences connected with the heat treatment of steel." The principal means for this purpose are to be the holding of meetings for the reading and discussion of papers bearing upon processes, apparatus, instruments, etc., employed in research work and practice connected with the art of heat treating.

This Society is experiencing a rapid growth and a chapter with a large membership has already been formed in Cleveland, Ohio, while movements for chapters in other cities are under way. One of the aims of the Society is to reach into the heat-treating rooms of the various industries, and to further the worker's knowledge of the art by bringing him out to its meetings, where he will come into intimate contact with metallurgists, chemists and scientific men.

The society publishes a monthly journal which already contains a considerable amount of valuable material and undoubtedly will prove of increasing value. The Secretary, Mr. W. H. Eisenman, 154 E. Erie Street, Chicago, Ill., advises that many manufacturers have been quick to see the direct financial benefit to be derived by placing one or more of their staff in the society—one firm has 12. At a recent meeting in Chicago it was found that the interest in the subject was so great that several engineers came from distances of 80 and 100 miles to attend.

The Engineers' Club of St. Louis Alive to Municipal Affairs

In his letter this month Secretary Rice calls attention to the participation by the Engineers' Club of St. Louis in discussions relative to a municipal bond issue of that city, and in connection with this the following letter received from the secretary of the Engineers' Club of St. Louis will be of interest:

To the Editor:

Meetings of the Associated Engineering Societies of St. Louis were held on February 5 and 12 for the discussion of the proposed $23,384,000 St. Louis municipal bond issue.

Topics of this kind are considered by the Engineers' Club of St. Louis and Associated Societies in conformity with a resolution adopting the principle of taking an active interest in economic, industrial and civic affairs.

Both of these meetings were a marked success in interest evi-

denced as well as in attendance. At the meeting of February 12 the attendance was double the average attendance.

As practically all of this proposed bond issue would be spent for municipal improvements directly involving engineering and the engineer, it is only natural that the engineer-citizen and the engineers as a body should give it due consideration.

The several items in the detailed budget of the proposed bond issue were presented to the meeting by engineers in the city employ who are in charge of the several departments of the public works concerned. In this manner the subject was placed intelligently before the members. The presentation of the subject took up the entire meeting of February 5. At the meeting of February 12 the discussion of the subject was continued and led by members of the Civic Committee of the Engineers' Club, which committee also had the matter under investigation for report. A very lively discussion developed at this meeting, and at the hour of adjournment was not nearly concluded; a resolution was therefore adopted requesting the Civic Committee of the Engineers' Club to report its recommendations at an early date relative to the issue to the Joint Council of the Associated Societies for further action.

Engineering subjects of public importance and matters affecting the engineer or the engineering profession are promptly considered by the Associated Engineering Societies of St. Louis in an endeavor to enlighten the public and to put on record an expression of the profession.

Joseph W. Peters,
Secretary.

American Society of Heating and Ventilating Engineers

The twenty-fifth annual meeting of the American Society of Heating and Ventilating Engineers was held at the Engineering Societies Building, New York, January 28-30, 1919, important features being the presentation of a number of valuable technical papers and the election of fifteen members chosen from among the different fields of activity of the society to constitute a Bureau of Research which will conduct experimental studies in coöperation with the Bureau of Mines. Funds are being collected to finance the work and the committee will undertake research work on the transmission of heat and similar engineering problems. The announcement of this commendable enterprise aroused considerable enthusiasm among the members and the opinion was generally expressed that the work will soon develop into a permanent activity for the good of the profession.

Dr. Emery R. Hayhurst presented the results of his experiments to determine the feasibility of maintaining in the ordinary house a proper humidity (40 to 50 per cent), comfortable temperature, and healthful atmosphere during the closed-up season of the year. His observations went to show that it requires up to 20 gal. of water per day (depending upon the temperature of the air to be heated and its rate of escape from the house) to supply sufficient water vapor for the air; he therefore recommended that some continuously operating device, such as an atomizer, be connected with the water supply of the building.

In a forceful discussion Dr. E. Vernon Hill pointed out the comparative values of mechanical and natural ventilation. The problem of ventilation, he remarked, is to determine what air conditions are desirable in a given space with a given type of occupancy, occupation, etc., and then to decide from experience and from tests in similar buildings whether these conditions can be maintained without mechanical ventilation; if they cannot, the mechanical adjuncts necessary to secure them will have to be adopted.

Air washing and humidification in school buildings was treated by Perry West, who emphasized the necessity for maintaining a constant degree of relative humidity in class rooms by quoting the New York State Commission on Ventilation. This body has conclusively proven, he asserted, that the enervating effect of 78 deg. as compared with 68 deg. for the air surrounding pupils reduces by at least 35 per cent their inclination to work. Mr. West explained that it is better to maintain the humidity at a convenient value than to raise the temperature alone to the point of comfort. Thus, for instance, on a zero day with 50 per cent humidity the air would have to be raised to 87 deg. to feel comfortable, and would then have a humidity of 2 per cent; if, however, by suitable humidification the air is maintained with a relative humidity of 50 per cent, the temperature would feel comfortable at 67 deg. and there would then be no enervating or devitalizing effect.

F. J. Hoxie called attention to the importance of properly arranging heating pipes to prevent decay of factory roofs. It appears from the records of his observations of the condition of various roofs that an effective protection of sawtooth roofs against decay is afforded by locating part of the steam pipes at the back of the sawtooth farthest from the windows. He illustrated his talk with several instances of roofs which had rotted in a few years in the part of the sawteeth where the heating pipes were placed directly under the windows and were well preserved where the pipes ran along at the bottom of the sawteeth.

Other papers were: The Transfer of Heat, by Geo. A. Orrok (referred to elsewhere in this number); Air Duct Design, by Leo Kraft; Dust Determination in Air and Gases, by E. R. Knowles; Fuel Conservation by Means of Automatic Temperature Regulation, by F. A. DeBoos; A Test of the Conductivity of Window Shades, by John R. Allen; Limiting the Fuel for Domestic Heating, by Konrad Meier; Engineering Economics of Heating, by M. W. Ehrlich; and By-Product Coke, by William T. Harms.

Society of Automotive Engineers

The annual meeting of the Society of Automotive Engineers was held in New York, February 4 to 6, 1919, at which papers were presented embracing a wide range of subject-matter. Mr. Chas. M. Manly was elected president for the coming year.

Among the papers dealing with war topics was one on Problems of the Naval Aircraft Factory During the War, by Commander F. G. Coburn, in which the splendid work done by the factory was described and the many expedients resorted to for improving the work shown. Airplane and Seaplane Engineering, again from the point of view of the work done by the Navy, was discussed by Commander H. C. Richardson, who showed, among other things, a chart for determining the efficiency of propellers and considered briefly the general matter of design of propellers, sea floats and seaplanes.

Two historical papers were also presented, one on The Story of the U. S. Standard Truck, by J. G. Utz, and another by J. G. Vincent, Mem.Am.Soc.M.E., on the designing of the Liberty engine, including certain data on its construction.

The Relation Between Airplane and Automobile Engines was discussed by several speakers. It was quite natural that such a subject should come up, as the greatest part of the work in designing aeroplane engines for the United States Government was carried on in automobile factories under the supervision of their own engineers.

Howard C. Marmon pointed out the essential factors controlling the design of areoplane and automobile engines and their differences. Thus, the automobile engine, besides being built for work under entirely different conditions both as to operation and maintenance, would not equal the aeroplane engine in power per cubic inch of piston displacement as it had to be carbureted for greater flexibility and not solely for maximum torque output through a comparatively limited range of speed. Neither could it use two or four carburetors like an aeroplane engine. An automobile engine could not use the high-compression pressure of an aeroplane engine as this would be impracticable at the full load, at low engine speeds and in climbing. Further, the lower-grade fuels commonly used in automobile engines gave more trouble under high compressions than the fuels customarily used in aeroplanes. Other points of difference in construction and design were considered; among other things being the fact that if an automobile engine were built with the same easy clearances on the pistons and the ample freedom given all the bearings it would make so much noise as to be entirely unsuitable for ordinary use. On the whole, the conclusion of the speaker was that the aeroplane engine was a more expertly engineered and manufactured development of the internal-combusion engine than the automobile engine. It was, however, developed for a set of objectives differing from those demanded in an automobile and none of its major features could be directly grafted upon the motor car. Further,

TABLE 1 AVAILABLE OIL REMAINING IN GROUND, AS ESTIMATED BY THE U. S. GEOLOGICAL SURVEY (BBL. OF 42 GAL.)

Oil fields	Marketed production in 1917	Marketed production in 1918 (preliminary estimate)	Total marketed production to end of 1918	Available oil left in ground, January 1919	Present average gasoline extraction, per cent
Appalachian	24,932,205	25,300,000	1,221,737,000	550,000,000	28.0
Lima, Indiana	3,670,293	3,100,000	448,404,000	40,000,000	20.0
Illinois	15,776,860	13,300,000	298,159,000	175,000,000	22.0
Mid-Continent	144,043,596	139,600,000	990,573,000	1,725,000,000	24.0
North Texas	10,900,646	15,600,000	78,971,000	400,000,000	33.0
North Louisiana	8,561,963	13,000,000	90,902,000	100,000,000	28 0
Gulf	24,342,879	21,700,000	303,954,000	750,000,000	1 5
Wyoming	8,978,680	12,370,000	39,793,000	400,000,000	40–50
California	93,877,549	101,300,000	1,114,000,000	2,250,000,000	12.0
Alaska, Colorado, Michigan, Montana, etc.	230,930	230,000	10,651,000	350,000,000	....
Total	335,315,601	345,500,000	4,598,144,000	6,740,000,000	....

the speaker believed that motor cars would be improved as a result of aeroplane experience and that this would come about as a result of better manufacturing facilities, higher shop standards and more intelligent inspection rather than from any radical changes in design.

Essentially the same view was supported by the other speakers. Henry M. Crane said that he felt certain that there was no reason to expect any radical change in automobile design due to aircraft-engine development, though in racing cars the effect of aviation-engine progress was bound to be considerable, as the service required was very similar in both cases. In his opinion, the motor-car engine should be designed to develop its best pulling characteristics at considerably lower speed than does the aircraft engine, which will undoubtedly mean very much lower compression ratios and lower mean effective pressures.

O. E. Hunt gave further arguments to support the same contention. He pointed out that an aeroplane is almost entirely devoid of a power-transmission system. The conventional aeroplane engine has the propeller mounted directly on the end of the crankshaft. For certain purposes, reduction gears of a fixed ratio are used to drive from the crankshaft a lay shaft carrying the propeller, but gear changes, such as are applied to cars, are unknown. The only element of the power transmission that has a counterpart in car work is the propeller hub, which performs a similar function and is similar in design to the rear-wheel hub of cars. Aeroplane-propeller hubs must be readily demountable and this requirement has resulted in some new design details that are entirely unnecessary for cars.

The engine requirements for aeroplane service are so different from those for cars that factors which are vital in the former type of machine are of minor importance in the latter, and vice versa.

Like others, Mr. Hunt believed that the influence of aeroplane experience on automobile-engine design would be of an indirect nature—mainly in bringing about better methods of production and a higher regard for metallurgical practice.

An important section of the meeting was devoted to the consideration of the present fuel situation, in the course of which data of great interest were presented by various speakers.

E. W. Dean, of the U. S. Bureau of Mines, told of the status of refinery practice with regard to gasoline production. He said the refiner might be able to augment his production of gasoline from a given amount of crude petroleum by from 35 to 40 per cent, exclusive of the gains possible through wider application of the cracking reaction. Some of the possibilities, however, overlapped each other, and a more probable summation estimate was 25 to 30 per cent. The Bureau believed that, if commercial developments were favorable, the wider use of cracking processes might permit of further increases up to a possible additional 100 per cent. No prediction, however, was ventured as to what part of this figure would actually be attained.

It might be mentioned, also, that the development of engines capable of utilizing the combined gasoline and kerosene fractions of crude petroleum would not be likely to alter the limit of maximum increase, but would materially hasten the day when it would be attained, and would in considerable degree help to keep the price of liquid fuel from ascending to painfully high altitudes.

Mr. Dean's paper may have produced the impression that the Bureau of Mines is not enthusiastic over the advantages to be gained by the development of a kerosene-consuming internal-combustion engine. Such is not the case, but it must be emphasized that this is not the only line along which the automotive industry must work.

Jos. E. Pogue, of the Bureau of Oil Conservation, Oil Division, U. S. Fuel Administration, summed up the present engine-fuel situation by stating that the principal factors are the demand for liquid fuel and the adaptability of the internal-combustion engine on the one hand, and the supply of crude petroleum, the gasoline-producing capacity of this material, and the substitute fuels in sight, on the other. On the whole the speaker claimed the automotive industry is working without due regard to the engine-fuel situation, that the domestic production of crude petroleum is nearing its maximum, and that the natural-gasoline content of this fuel is lessening. Conditions in Mexico are such that no adequate relief may be expected from that source. Substitute fuels need not enter into present consideration and cracking cannot meet the issue at a favorable price. The burden, therefore, falls upon the automotive engine, which must consequently so adapt itself as to gain higher thermal efficiency, and to use less specialized (less volatile) fuel.

As an emergency measure, therefore, the automotive industry should at once take steps to shape its development in the direction of increased fuel economy and less specialized requirements as to fuel, establishing for this purpose centralized machinery to study the problem in full detail; should keep the industry informed of every development in the situation; should coördinate research and design in the competing units of the industry; and should conduct basic lines of research not now adequately encompassed by individual agencies.

The question of petroleum supplies in the United States and Mexico was covered respectively by Davis White, of the U. S. Geological Survey, and R. de Golyer, a consulting geologist of New York City, neither of whom gave very encouraging promises. Table 1, presented by Mr. White, is of particular interest as giving an authoritative estimate of the available oil remaining in the ground in this country.

While it is quite likely that the amount of fuel underground in Mexico is very great, there are both political and technical conditions which make it impossible to consider that country as a source of *speedy* relief for the existing situation.

Mexican petroleum is not refined as extensively as American, and the speaker stated that the greatest possibilities for future extended uses of Mexican petroleum seem to lie either in the further perfection and more widespread development of combustion engines using very heavy oils as fuel or in an improvement of refining methods by which heavy oils can be more easily converted into lighter oil.

Engineering Institute of Canada

THE annual meeting of The Engineering Institute of Canada, which was combined with a general professional meeting, was held in Ottawa, February 11, 12, and 13, and was one of the most successful ever held. The large attendance and the en-

thusiasm prevailing are evidences that there is a greatly increased interest being taken by Canadian engineers in their profession and show clearly that the recent changes in the organization were well justified.

The preliminary session of the Annual Meeting was held in Montreal, as prescribed by the by-laws, and was adjourned to Ottawa, February 11, with headquarters at the Chateau Laurier where all the meetings and luncheons were held. A notable feature of the gathering was the attendance of eminent engineers from the United States, all of whom gave addresses, including Dr. Comfort A. Adams, President of the American Institute of Electrical Engineers; Dr. Ira N. Hollis, Past-President of The American Society of Mechanical Engineers; Alfred D. Flinn, Secretary of the Engineering Council, and F. H. Shepherd, Director of Heavy Traction, Westinghouse Electric and Manufacturing Company. Other speakers outside of the membership of the institute were, The Duke of Devonshire, Hon. F. B. Carvell, Minister of Public Works, and The Hon. Arthur Meaghan, Minister of The Interior.

The first day's session, and part of the morning session of the second day, were devoted entirely to business, including a report of council, reports of library and house committee, finance committee; papers, board of examiners, and education, publications committee, international electrical technical committee, engineering standards committee, roads and pavements committee, and the reports of the branches. In Canada the branch societies of the Engineering Institute comprise the local engineering bodies, the membership including the members of the institute of all grades, who reside within 25 miles of the branch headquarters and branch affiliates. They conduct their own affairs, and elect their own members of council, and the reports show them all to be in an active flourishing condition.

The report of the Honor Roll Committee showed the great part that Canadian engineers have played in the war. The scrutineer's report, read by the secretary, announced the officers, with Lt.-Col. R. W. Leonard, M.E., as president.

A special meeting of the representatives of the various branches appointed to consider the subject of legislation placed a resolution before the meeting, which was adopted, to the end that a special committee be formed to meet at headquarters, before the 15th of April, 1919, to draw sample legislation, and that they submit the proposed legislation to the council before the 1st of May, following which a letter ballot will be issued to all the members and, if favorable, steps taken to secure legislation.

In his presidential address Mr. H. H. Vaughan, Mem.Am.Soc. M.E., told the story of munition production in Canada, which showed the remarkable proportion which it assumed.

The Gzowski medal, which is awarded every year for the premier Canadian paper on an engineering subject, was given to B. F. Haanel, M.E.I.C., for his paper on the Fuels of Canada.

Of the addresses given during the meeting of the Engineering Institute of Canada, we are fortunate in having the text of the remarks by Dr. Ira N. Hollis, Past-President, The American Society of Mechanical Engineers, given at a luncheon on February 12. Dr. Hollis was in his happiest mood and with clear vision and keen analysis spoke of the relations between Canada and the United States, and the part which each had played in the war. Dr. Hollis' address follows.

Address by Dr. Ira N. Hollis

A Broad View of the Aims and Opportunities of the Profession

I want to assure you that for a number of reasons it is a real delight to me to come to Canada, one of them being that I promised two or three times while I was President of The American Society of Mechanical Engineers to come to Ottawa, and every time I had to break my promise for some reason connected with our entering the war. This is, therefore, a redemption of my promise to friends in Ottawa and Toronto.

Another reason why I am glad to be here is that it affords an opportunity of congratulating you on the statement of the aims of your institute which appears on the cover of your journal. We as engineers often fail to understand the significance of our own profession. It is not necessary to shout from the housetops, but who has ever produced a better motto for an institute such as this than the following:

> To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession, and to enhance the usefulness of the profession to the public.

Numerous committees of The American Society of Mechanical Engineers, the American Society of Civil Engineers, and the Engineering Council have endeavored to state the aims and purposes of our societies, but with all our attempts in the past we have not produced anything as good as this.

I think that in The American Society of Mechanical Engineers the percentage of technical papers has decreased in proportion as the papers intended to be useful to the public have increased. I do not know whether that is the best thing for a technical society, but I do know that it bids fair to make our profession in the United States a profession of better citizenship. We must never forget that the purpose of any technical organization like ours or like this is mainly educational—to teach its members how to do their work better and how to serve the public and build up their relations with it in a better way.

Another reason for my coming here is deeper and broader than anything I could state in regard to our profession; it relates to your part in the war. Although much smaller in population than the United States, you, gentlemen, are our older brothers in arms. Upon your shoulders fell the first shock of the war as you rallied so splendidly to the defense of human liberty. I can state nothing better in this connection than two or three sentences contained in a letter from a relative on the other side who went in at Chateau-Thierry and ended up at Stenay. Every one of his letters contains some stronger statement of this sentiment. He said: "As the time goes on and I learn more about this war, I take my hat off to the British and Canadians who fought here in the beginning. We came in with our army as a large reserve, we fought in some important actions, and we were getting more troops to the front, but we came in at a time when the Germans were putting forth their last great effort after time for ample preparation, whereas the British and Canadians had to prepare while they were fighting. I take off my hat to them." I cannot help feeling, gentlemen, that that is the finest reason of all for my coming up here to salute you.

I look upon our race as the inheritors of the liberties of this world. After all, we have the English ideals of government on this continent, and we have to make all those who come to our shores from other countries English in ideals. South of the line we call ourselves Americans, and we call you Canadians, but we are all Americans in the freedom of the atmosphere in which we live. I come from that federation of states which split off from the mother country more than a century ago through a document written, after all, by Englishmen—one of the noblest statements in our language next to the Magna Charta. We are all Americans, and we have here on this continent the best league of peace that I can imagine. No fortifications on our boundaries, and war is unthinkable north of the Rio Grande. Our league is written in the hearts of two peoples who do not resort to bloodshed to settle their differences. As we meet here the Peace Conference is sitting in Paris and is working toward definite action—for what? It will be the most important decision ever made in the world, and it will be framed into some kind of statute where the cowardly bully who has bathed the soil of France in the blood of our sons and covered the ocean with ships and the bodies of the innocent is up for sentence to be rendered impotent until the centuries shall have turned him into a Christian.

So far as our profession is concerned, I am glad to bring the greetings of The American Society of Mechanical Engineers. We have the same warmth of feeling toward you that we have toward our members in the States, and we congratulate you on the formation of an Institute containing all the societies of engineers in the

youth of those societies. We have a harder task ahead of us in the United States to make one great society of engineers, because each separate society has already crystallized into its own methods and its own policies, thus rendering it difficult to form a union of all.

The Opportunities of the Profession

At the beginning of one of Mr. H. G. Wells' books you will find this sentence: "Civilization is advanced in proportion to a man's control over power outside of himself." Through what James Watt gave to mankind a little over a century ago we have entered our present era, the possibilities of which are not even thought of, inasmuch as we can use the power and energy that God placed on this earth for the development of man into something higher and far better than has gone before. Some day this century will seem but as the dark age to our descendants, and that mainly through the control of power entirely outside of man. I speak of this because that gives you plainly and at once the function and the place of the engineer.

I was speaking in New York not very long ago on the subject, Is Science Safe for Mankind? I dealt with the subject in all seriousness, for if science can be turned into a destructive agency to cover the earth with blood and to destroy all that has been previously produced, it is not safe. How can it be made safe? It can be made safe through our profession by approaching the discoveries and applications of science in that reverent attitude that will forever prevent its being used as a destructive agency. What does it amount to if we produce another railroad, another dock, a finer type of bridge, or a better machine, if it but leads to a conspiracy for the control of the earth? What does efficiency amount to if that, after all, is the end; if it places in the hands of the privileged few the control of the masses who are to be trained to service very much as the ox or the hórse is trained?

The Engineer and Conservation

Another feature of the engineering profession is its opportunity to teach that proper attitude of mind toward the patrimony that nature has handed dowu to us on this continent so that we may prevent its being used or wasted in the destruction of mankind by self-indulgence or war. I can speak, perhaps, for the United States as I saw it before we entered the war. We were the most wasteful people on the face of the earth. We had found in our country immense resources which we prided ourselves on exploiting for the luxury and the greed of a great many people. But this war has brought to our profession a different vision, and we have certain things to think of. The first is found in the word "conservation," which has grown up in the United States, and which I have no doubt you have in Canada. What is the significance of it? It means the saving of everything that will help to perpetuate the influence of the Anglo-Saxon race; it means the saving of anything that will promote our ideals as a race; that our language and our efforts may civilize this whole world, the Germans as well as the others. I cannot help feeling that there are two or three aspects of that to which we have given but little attention. My interest in the matter was aroused in Massachusetts, because during the past eighteen months I have assisted in the conservation of fuel for that state. In Worcester, through an effective committee of manufacturers, where there are 200,000 people, during the past year we saved, not by cutting off any industries, but by actual scientific study of the problem of saving in our power stations and in our factories, 125,000 tons of coal —a million dollars saved for that city alone during the past year. In a state which takes 12,000,000 tons of bituminous coal in the course of a year, we saved at least ten per cent; and we were rash enough to promise Mr. Garfield and the Fuel Administration that we would take two and a half million tons less during this year than we took the previous year. We had just touched the fringe of this subject when the armistice was signed and the bottom dropped out of the whole movement. Are we going to permit this effort throughout the United States to break down? Not at all.

In my state—but it is not my state; I was born in Kentucky— when I went as a professor to Harvard College years ago, my picture was published in the Louisville *Courier-Journal;* and lest I should become vain on that account, my photograph was bracketed on the same page with a man who had been hanged in Louisville the day before. One of my friends saw that picture, an old farmer whom I had known in my youth, and who was living in Jefferson County, Kentucky. He said to me: "I see you have resigned from the Navy and are going to Harvard College as a professor." I said: "Yes." He said: "For God's sake don't do it; you are going amongst those d—— Yankees." The New England people do not like that story very much, but it shows that sometimes misunderstanding can exist among our states, the same as I have sometimes heard of between Canada and the United States. But whatever misunderstandings have occurred between those two countries, they do not approach some of the former bitterness between the North and the South; do not approach some of the misunderstandings between the different states. That man who was talking to me about New England knew nothing about the spirit which existed there, nor of the generous attitude of the people toward everything that has a value to the public. You will find in New England the same broad generosity to be found in Canada, if you look for it.

Returning to the subject of conservation, we have not only learned to save coal, but to save food; we have reduced the amount of transportation for unnecessary commodities and thus have made our railroads more effective. Saving can be effected in every respect, even in our water power. Indeed, there is nothing in which there is not room for further study and coöperation to the end that America—Canada and the United States—may remain as long as possible the chief influence for good on this earth.

Importance of Standardization

Next to conservation, standardization is the most important subject we have to deal with. There is an enormous amount of waste in the production of a great many articles which should be duplicates. There is not one aspect of manufacturing connected with engineering that is not susceptible of improvement by coöperation among manufacturers, to the end that articles for like purposes shall be produced in the same way and shall be standard. I think our economic supremacy among the nations is dependent upon this.

Engineers Must Equip for Administrative Work

Then there is the labor question. During the past six months we have been involved in the United States in the question of the relation between labor and the employer and in the reëmployment of soldiers. I do not know any men who are better qualified to take a hand in that than the engineers. But in this connection I want to destroy what may be called another illusion; a man is not competent to organize and direct industries or to handle labor questions simply because he is an engineer; he may only become competent by interesting himself in them if it is in his natural field. I have heard a great many people say: you ought to put engineers in the Administration. I say, not unless they fit themselves to go into the Administration. I have heard again that the engineer ought to take an active part in politics and in the public life of his country—not at all, unless he fits himself for it; and it is his business to fit himself. In other words, our profession is a great profession only in proportion as we make it so, and not by reason of the fact that we are called engineers.

Service in Peace as Important as Service in War

We talk about this having been an engineers' war, about machinery having won the war. But it is the blood of our sons which has won the war; it is the men who have done it. When I heard the statistics read by your president yesterday, I rejoiced that men in my profession, members of this Institute, could so help the world in this crisis. Of course, we were not in it so long; I sometimes think we were tardy in getting in. We got there, and we might have done a great deal more and suffered a great deal more if you fellows had not pretty nearly cleaned up

the thing before we got in to help. Nevertheless, we ought to keep in mind the fact that machinery alone did not win the war; what brings such a victory as ours is the willingness of men to give their lives for a great cause.

The same thing applies in time of peace; a man may help his country and the community by willingness to dedicate himself to a profession, to give himself to the advancement of the human race; and that willingness is expressed in the one word, "service." If I were to try to visualize the condition necessary to the progress of the world to-day, I would express it in two words, in the nature of a formula for our profession: "to serve." At the beginning of the war we heard very much the phrase "to make the world safe for democracy." After all that is but a method of saying that we are seeking a form of government for the human race that will permit every individual to develop the maximum of his possibilities in the service of mankind. That is what democracy means. Our profession will have great power in the near future of peace, in the league of nations, because no league of nations will last if the proper spirit is not there. Without that attitude of mind, we cannot achieve what should be our great purpose.

About two months ago it was proposed in New York that The American Society of Mechanical Engineers go to London for a meeting in a year or two. What I want to see within the next two years in London or Paris is a great meeting of all the engineers of this continent—civil, mechanical, electrical, mining—met together to rejoice over that peace that I hope is going to come out of the present proceedings in Paris.

NECROLOGY

ABRAM T. BALDWIN

Abram T. Baldwin was born on September 26, 1870, in Yonkers, N. Y., and was educated in the public schools and Cornell University, graduating from the latter with the class of 1893.

Upon graduation Mr. Baldwin first worked in the Wm. A. Sweet Rolling Mills, Syracuse, N. Y., and served his apprenticeship in practically every branch of the industry. In January 1895 he became connected with the Solvay Process Co., also in Syracuse, where he worked through the various departments, being assistant manager of the soda ash department at the time he left Syracuse to enter the coke department of the same company in Detroit. In May 1910 th Precision Instrument Co. was organized, in which Mr. Baldwin was very much interested. It was not until 1911, however, that he gave this company his full attention and at that time he became its treasurer; in 1913 he was made president and general manager of the firm, which position he was holding at the time of his death.

When the United States entered the war, Mr. Baldwin was asked to take up the manufacture of air-speed indicators for the Science and Research Division of the Bureau of Aircraft. His work in this connection was so arduous that it resulted in his physical breakdown and sudden death from heart collapse on January 8 in Boston.

Mr. Baldwin was greatly interested in the combustion of coal and efficiency of boiler operation. He was a member of the Detroit Engineering Society, the National Association of Stationary Engineers, the American Gas Institute and the Detroit Board of Commerce. He became a junior member of the Society in 1899 and in 1902 a life member.

CHARLES C. CHRISTENSEN

Charles C. Christensen was born on September 30, 1851, in Copenhagen, Denmark. He attended the technical college at Navy Yard, Horten, Norway, where he studied marine and mechanical engineering. He served an apprenticeship in shop practice and drafting from 1871 to 1875 in Norway. The next four years he worked with the firm of Jansen & Dahl, Norway, as a designer on iron vessels and on engines.

In 1880 Mr. Christensen came to the United States, where he was employed by the Allis-Chalmers Co. as draftsman. From 1882 to 1888 his position was that of designer of mining machinery and at the end of that period he was placed in charge of the engineering and drafting department. From 1889 until the time of his death, December 13, 1918, he held the position of estimating engineer.

Mr. Christensen was the author of a number of articles relating to mining machinery which have been published in both American and English mining journals and also translated for Spanish and German technical periodicals. He became a member of the Society in 1890.

MICHAEL JOSEPH GOLDEN

Michael J. Golden was born on November 17, 1862, in Stratford, Ont., Canada. He received his early education in the schools of Lawrence, Mass., and later attended the Massachusetts Institute of Technology for two years as a special student. He served an apprenticeship with William McCartney in Lawrence and was for six years assistant to E. Lyford.

For one year he was an instructor in mechanical drawing at a high school in Hyde Park, Mass. In 1884 he became connected with Purdue University, Lafayette, Ind., as an instructor in shop work, later receiving his degree in mechanical engineering from the University. From 1889 until June 1916, when ill health compelled his resignation, he served as professor of practical mechanics at Purdue, and from 1907 was also director of the practical mechanics laboratory. He was considered an authority in shop management and shop experience and his course of shop lectures was widely known. He spent much of his time in research, investigating microscopically the structure of wood, for this purpose designing and building much special apparatus.

Professor Golden was the author of several works on mechanics and of a number of shorter articles which appeared in the technical press. He was a member of the Indiana Academy of Science, the American Society of Naval Engineers and the Manual Training Teachers' Association of America. He became a member of the Society in 1892. His death occurred on December 18, 1918.

LAURENCE RICHARD GULLEY

Laurence R. Gulley was born at Mason, Mich., on August 14, 1888. He attended the University of Illinois, receiving in 1910 his B.S. degree in mechanical engineering (M.S. in 1911; M.E. in 1917). From 1908 to 1911, during his vacations, he was connected with the Burr Co., Champaign, Ill., as draftsman.

Upon graduation he was employed by the same company and from 1911 to 1913 he served as chief engineer. In 1913 he became general manager of the firm and at the time of his death, October 24, 1918, in addition to holding this position, was also secretary of the Burr Co.

A short while previous to his death Mr. Gulley had designed and built the Gulley tractor dynamometer, which has proved of much interest to tractor-manufacturing concerns.

Mr. Gulley was a member of the honorary societies of Tau Beta Pi and Eta Kappa Nu. He became an associate-member of the Society in 1917.

GEORGE SHERWOOD HODGINS

George S. Hodgins, editor of *Railway and Locomotive Engineering*, died at his home in New York City on January 18, 1919. He was born in 1859 in Toronto, Ont., and was a graduate of the Upper Canada College and the school of practical science, University of Toronto.

He served his apprenticeship with the Canadian Locomotive & Engine Co., Kingston, Ont., in machine-shop work, locomotive erecting, etc. In 1882 he was appointed draftsman in the same company and was directly responsible for locomotive design. After some experience in a division master mechanic's office on the Canadian Pacific Railway, he was advanced to various positions on the road and of late was locomotive inspector on the entire system. In 1889 he was recalled to the Canadian Locomotive Works as mechanical engineer, where he had charge of all engineering and designing work. Later he entered the service of the Pressed Steel Car Co., Pittsburgh, Pa., as general inspector of the output of that extensive plant, and was also for some years inspector of the Richmond Locomotive Works.

During these earlier years he had contributed to a number of railroad publications. In 1900 he entered the field of practical journalism as editor of *The Railroad Digest*. In 1902 he joined the staff of *Railway and Locomotive Engineering* as associate editor and in 1908 became managing editor, which position he held until 1911, when he was called by the Canadian Government to make a comprehensive report on the shops, appliances, tools and equipment necessary for the Trans-Continental Railroad. On the completion of that work in 1915 Mr. Hodgins joined the staff of the Railway Periodicals Company as managing editor of the *Railway Master Mechanic* and *The Railway Engineering and Maintenance of Way*. In 1916 he returned to *Railway and Locomotive Engineering* and remained on the staff as editor until his death.

He contributed many articles to popular science magazines and as a writer on engineering and technical subjects his style was marked by an exact and comprehensive lucidity.

Mr. Hodgins became a member of the Society in 1908.

HENRY SMYTH ISHAM

Henry S. Isham was born in New Britain, Conn., on March 16, 1866, and was educated at Mowry and Goff's English and Classical School, and at the Bryan and Stratton Business College in Providence, R. I.

He first served an apprenticeship of three years with the Harris-Corliss Engine Works, Providence, and then entered the service of

the Rhode Island Locomotive Works in the capacity of draftsman. From that position he went as draftsman with the Jeffrey Manufacturing Co., Columbus, Ohio, and in the following year, 1892, he became connected in the same capacity with the Johnson Steel Co., Johnstown, Pa. Mr. Isham's next position was with the Pond Machine Tool Co., Plainfield, N. J., as draftsman. The year of 1895-1896 he was with the Washington, Alexandria and Mount Vernon Railway, and a little later was located in the chief engineer's office of the Central Railroad of New Jersey. For over a year he worked with the Mossberg Manufacturing Co., Attleboro, Mass., leaving that firm to take a position in 1897 with the Metropolitan Street Railway Co., New York City, as track expert in the office of the engineer of maintenance of way. From 1899 to 1901 he was designing draftsman for the São Paulo Railway, Light & Power Co., Ltd., São Paulo, Brazil, S. A.

In 1901 Mr. Isham returned to the United States to enter the employ of the Pennsylvania Steel Co., Harrisburg, Pa., remaining there until 1903. From 1903 to 1908 he was chief draftsman with Ford, Bacon & Davis, New York City, and then became associated with the New York Railways Co., where he had charge chiefly of the track work. His next connection was again with Ford, Bacon & Davis as chief draftsman. About the middle of 1918 he entered the service of the New York Edison Co., New York City, and was with that company at the time of his death, which occurred in an accident on November 28, 1918.

Mr. Isham became a member of the Society in 1902.

PAUL JONES

Paul Jones was born in Wilmington, Del., on May 11, 1881, and was educated in the schools of that city, later attending the Heath School. He studied as a special student in mechanical and mining engineering and in 1902 took a position with the Diamond Steel Co., Wilmington, where he was engaged in general drafting for iron- and steel-works equipment, later becoming engineer of tests and then assistant to the superintendent of shops and steel products.

In 1906 Mr. Jones became connected with the E. I. du Pont de Nemours Co., Wilmington, in the light, power and heat division. His duties were in the general office and in field engineering work in connection with construction, design and maintenance of power plants and power transmission systems and costs. His next position was in 1909 with the H. C. Frick Co., United States Steel Corporation, Pittsburgh, Pa., as assistant engineer for the design of coal and coke plants, railroad trackage and structures, power plants, etc. For the year 1910 to 1911 Mr. Jones's services were loaned to the G. S. Baton Co., as construction engineer, where his duties were along the same lines as they had been with the Frick Co. He returned to the employ of the Frick Co. and was made plant superintendent of the Filbert Works. He completed this plant, developing and maintaining all plant operations.

In 1914 he became associated with the Bosch Magneto Co., Plainfield, N. J., as works engineer. He was engaged in the design, construction and maintenance of buildings and equipment and the direction of power-plant systems. In the Spring of 1918 he was commissioned a first lieutenant in the Aviation Section, Signal Reserve Corps, of the Army and was assigned to duty in the finance department. At the time of his death, December 17, 1918, he was connected with the Air Nitrates Corporation, New York, having been honorably discharged from the service.

Mr. Jones was a member of the American Institute of Mining Engineers. He became an associate-member of our Society in 1917.

GEORGE ALEXANDER JUST

George A. Just was born in 1860 in New York City. He attended Rensselaer Polytechnic Institute, from which he was graduated in 1881 with the degree of C.E. He was first employed by the Phoenix Iron Works, and then was connected with the New Jersey Steel and Iron Co., Trenton, N. J., later acting as engineer for that firm in New York. He was also chief engineer of the Jackson Architectural Iron Works, afterward becoming a member of the firm Lewison & Just, consulting engineers.

Mr. Just was a pioneer in the steel industry and was at one time associated with Cooper, Hewitt & Co., and was one of the first engineers to develop the modern steel-frame building. At the time of his death, December 27, 1918, he was president of the George A. Just Co. He took an active interest in politics and was the engineer member of the commission which framed the Code of Building Laws for Greater New York, and from 1907 to 1915 served as chairman of the Board of Examiners of New York.

He was a member and ex-director of the American Society of Civil Engineers. He became a member of our Society in 1901.

DAVID TOWNSEND

David Towusend, a member of the Society since 1882, and vice-president during the years 1899 to 1901, died at his home in Philadelphia. Pa., on November 27, 1918.

Mr. Townsend was born on February 21, 1856, in Philadelphia. Pa. He was a graduate, class of '76, of the University of Pennsylvania, degree of B.S. In 1878 he was a special student at Stevens Institute of Technology, and assistant to Dr. R. H. Thurston and Prof. Albert H. Leeds. From 1878 to 1893 he was with the Bush Hill Iron Works, Philadelphia, specializing in rolls, rolling mills, steel and iron works construction equipment. He first served his apprenticeship in machine shop, foundry and drawing room, later becoming general manager. In 1893 he became general manager of the Philadelphia Roll & Machine Co., building and operating their works. He was with this firm until 1898, when he went to Germany to the Krupp Works at Magdeburg to study the methods and construction of the Gruson Revolving Coast Defense Turrets. Upon his return he designed, built and operated the Gruson Iron Works, Eddystone, Pa., as general manager. In 1903 this property was sold to the Baldwin Locomotive Works, who have since occupied it for themselves and for the Remington Arms Co.

From 1903 to 1912 Mr. Townsend was engaged in private engineering practice, specializing in iron and steel foundries, roll and rolling-mill designs and general construction for iron and steel products. Mr. Townsend became president of the Production Engineering Co. in Philadelphia in 1912, specializing in oil-burning apparatus of all kinds, holding this position up to the time of his death.

During the year 1916 he was also manager of the Philadelphia plant of the Neidich Process Co. and the Calco Chemical Co., producing aniline dyes.

AUGUST H. BORNHORST

Lieut. August H. Bornhorst was born on August 1, 1888, in St. Marys, Ohio. He received his early education in the schools of St. Marys and then attended Ohio State University, from which he was graduated in 1911 with the degree of M.E.

August H. Bornhorst

He first worked with the Ford Motor Co., Detroit, Mich., as machine designer on a 5000-hp. gas engine In March 1912 he was assigned through a civil-service appointment to the U. S. Engineer's Office, Seattle, Wash., as mechanical draftsman, where he designed cranes for handling concrete work and designed and laid out lock gates, lock-gate machinery and a proposed emergency dam. In March 1916 he became connected with the Puget Sound Navy Yard, Bremerton, Wash., as a marine-boiler and engine draftsman. Later he was connected for a short period with the Seattle Machine Works.

In July 1917 he entered the service as a first lieutenant in the Signal Officers' Reserve Corps and was afterward transferred to the Aircraft Production, Air Service Branch of the Army, in which he was serving at the time of his death, December 7, 1918.

Lieutenant Bornhorst became a junior member of the Society in 1916.

JOHN HORTON DALLY

John H. Dally was born on July 10, 1868, in Lafayette, N. J. He was educated in the public schools of Newark and later attended the Newark Technical School, of which he was a graduate. He served a three-years' apprenticeship with the Watts-Campbell Co., Newark, and from 1891 to 1895 worked in the shops of the same concern. He spent one year with the Richmond Locomotive Works and for the Whitehall Engineering Co. He was also connected for short periods with the Colorado Automatic Refrigerating Co. and with the New York Refrigerating & Construction Co. He was chief engineer of the Waldorf-Astoria Hotel, New York, for about a year and a half, and from 1896 to 1902 was chief engineer of the Carnegie Music Hall, New York.

From 1903 until the time of his death, December 23, 1918, he was chief engineer of the New York Stock Exchange. Since 1897 he had also acted as supervising engineer for the Fine Arts Society.

Mr. Dally became a member of the Society in 1903.

J. SELLERS BANCROFT

J. Sellers Bancroft, general manager and mechanical engineer of the Lanston Monotype Machine Company, of Philadelphia, Pa., died in that city on January 29, 1919.

Mr. Bancroft was born in Providence, R. I., in 1843. He became a member of the Society in 1880, and held the office of manager from 1909 to 1911, and that of vice-president from 1915 to 1917. A more extended notice will appear in the April issue.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by March 15 in order to appear in the April issue.

CHANGES OF POSITION

J. PAUL CLAYTON has resigned his position of commercial manager of the Middle West Utilities Company, Chicago, Ill., and has been elected vice-president of the Central Illinois Public Service Company, Mattoon, Ill.

FRANK H. ABBEY, for the past six years Boston manager for the Gifford-Wood Company, has been elected president of the Southworth Machine Company, of Portland, Me. The new duties, assumed on January 1, 1919, include the general management of the company.

LEMUEL C. BIGLOW, who for a number of years acted as New York manager for the Morse Chain Company, of Ithaca, N. Y., and who for the past year has been connected with the Charles A. Schieren Company, as manager of their engineering department, has been appointed eastern representative of the W. A. Jones Foundry and Machine Company, of Chicago, Ill., with headquarters in New York City.

MALCOLM M. HENDERSON has resigned his position as chief mechanical engineer of the Commonwealth Railways of Australia and has joined the Perry Engineering Company of Adelaide and Gawler, South Australia, as manager.

MANNING E. RUPP has severed his connection as superintendent of the ordnance department, Curtis and Company Manufacturing Company, St. Louis, Mo., to become associated with the Gifford-Wood Company, Hudson, N. Y., as general superintendent.

LEWIS S. MANFIELD has resigned his position as mechanical engineer with the Carver and Nate Company, engineering contractors, to accept the position of assistant to the secretary of the Heating and Piping Contractors' National Association, New York.

WILLIAM F. PARISH, for many years manager of the lubricating division of the Texas Company, and lately chief of the oil and lubrication branch, Air Service, War Department, has joined forces with the Sinclair Refining Company, Chicago, Ill. As technical director of the company, Mr. Parish will assist in organizing the section of lubrication engineering, and in connection with the lubricating sales department will aid in establishing broader and more direct representation.

FRED W. FISCHER has severed his connection with the United States Nitrate Plant at Muscle Shoals, Ala., to accept the position of boiler-plant supervisor with the Du Pont Engineering Company.

THEODORE H. HERMANSON, formerly with the Harrison Works of the Worthington Machinery Corporation, has become associated with the Epping-Carpenter Pump Company, of Pittsburgh, Pa., as works manager.

EDMUND S. HIGGINS, until recently affiliated with the Du Pont Engineering Company, Richmond, Va., has accepted a position with the Oakland Motor Company, Pontiac, Mich.

F. L. GILMAN resigned his position as works manager of the National Conduit and Cable Company last November, and has left for abroad to take a position as European general superintendent for the Western Electric Company, in charge of the company's manufacturing plants in England and on the continent.

ALEXANDER A. KOSWICK, formerly with Wright-Martin Aircraft Corporation at their Long Island plant, has accepted a position as an engineer with Ford, Bacon and Davis, in their valuation and report department, with headquarters in New York City.

ANNOUNCEMENTS

CAPTAIN JULIUS M. LONN, who for the past 20 months has been located in the small arms ammunition department at the Frankford Arsenal, Philadelphia, Pa., has been released from military service and has resumed his position in charge of engineering with the Great Western Manufacturing Company, La Porte, Ind.

G. CHARTER HARRISON announces that Eric A. Camman, associated with him since the establishment of the business, has been admitted into partnership. The firm will continue to specialize in the design of plans to meet modern industrial problems, under the firm name of G. Charter Harrison and Company, with offices, as heretofore, in New York City.

GEORGE H. SHARPE, until recently fuel engineer for the conservation department, United States Fuel Administration, has become associated with Frame, Friend and Stineman, Inc., New Haven, Conn., as consulting fuel engineer.

E. LOGAN HILL, secretary of the United States Shipping Board Commission on Port and Harbor Facilities, has resigned and has become associated with Heyl and Patterson, Inc., contracting engineers of Pittsburgh, Pa. Previous to his appointment as an official of the Shipping Board, Mr. Hill was assistant general manager of the Erie Railroad. He will be located at the New York sales office of the company, which is particularly interested in the application of their cranes to wharves, cargo handling and other special purposes.

THEODORE MAYNZ has become associated with the Gulf Pipe Line Company, Houston, Tex.

LIEUT. E. R. GLENN, who has been acting as production officer for the ordnance department at the Bethlehem Steel Company for the past year, has been discharged from the service and has become associated with the Simplex Valve and Meter Company of Philadelphia, Pa.

CLEON E. PHELPS, recently discharged from Government service, has accepted the position of assistant works manager of the Underwood Computing Machine Company, Hartford, Conn.

MAJOR JAMES GUTHRIE, Ordnance Department, U.S.A., has been ordered from Washington to Detroit, becoming engineering manager for the Michigan district, with headquarters at 818-820 Book Building.

E. HOWARD REED, vice-president of Reed and Prince Manufacturing Company, Worcester, Mass., is in the naval service and has been transferred from the torpedo station at Newport, R. I., to duty at Toledo, Ohio.

MAJOR R. W. FULLER, Ordnance Department, Washington, D. C., is leaving for Japan, China and Vladivostok, Russia, where he will represent W. R. Grace and Company of New York City.

PAUL P. BIRD has assumed the presidency of the Boston Sand and Gravel Company, with headquarters in Boston, Mass. He retains his partnership in the engineering firm of Norton, Bird and Whitman, of Chicago and Baltimore, and has opened an office for the firm in Boston.

L. H. THULLEN was elected president of the Grand Rapids Brass Company, Grand Rapids, Mich.

WILLIAM McCORMICK NEALE, formerly connected with the Newman Machine Company, Greensboro, N. C., as secretary, treasurer and mechanical engineer, announces the opening of an office in Greensboro for consulting practice, specializing in plant design, and the design and development of special labor saving machinery and devices.

W. S. QUIGLEY, president of the Quigley Furnace Specialties Company, Inc., sailed for Liverpool on the Baltic, February 15, for the purpose of further developing European connections of his company. Mr. Quigley will spend several weeks in England, France and Italy and visit the plants installing the Quigley system for preparing and burning pulverized coal and lignite.

APPOINTMENTS

CAPTAIN EDWARD E. ASHLEY, JR., for many years consulting mechanical and electrical engineer for Starrett and Van Vleck, architects, of New York, has resigned his commission in the Air Service of the U.S. Army to accept an appointment as sales engineer of the Mercury Manufacturing Company, Chicago, Ill. This company manufactures electrically driven tractors for use in connection with industrial haulage systems.

CHARLES W. STEPHEN has been appointed assistant works manager of Pratt and Cady Company, Hartford, Conn. He retains his present position as mechanical engineer.

MAX E. CUTTLER, formerly supervising engineer and superintendent of the Hamilton and DeLoss Company, Bridgeport, Conn., has been appointed general superintendent of The Hawthorne Company, which was merged with the Hamilton and DeLoss Company on February 1.

AUTHORS

S. H. GRAF has contributed an article on Structure and Strength of Overheated Rivet Steel to the February 6 issue of *Engineering News-Record*.

H. COLE ESTEP addressed the members of the Cleveland Engineering Society at a luncheon on January 31, on reconstruction work upon which engineers will be called. Mr. Estep was a member of a mission of fifteen technical experts invited by the British Government to inspect British industries and the western front.

DR. RICHARD MOLDENKE was the speaker at the New England Foundrymen's Association meeting, February 12. The subject of his address was Foundry Melting Methods.

LIBRARY NOTES AND BOOK REVIEWS

Our Cities Awake

OUR CITIES AWAKE. Notes on Municipal Activities and Administration. By Morris Llewellyn Cooke, M.E., Consulting Engineer, formerly Director of Public Works, City of Philadelphia. With Foreword by Newton D. Baker, Secretary of War. Doubleday, Page & Co., Garden City and New York, 1918. Cloth, 5 x 7½ in., 351 pp., 119 illustrations. $2.50.

Morris Llewellyn Cooke was a pupil and discipline of Frederick W. Taylor. Efficiency means more to him than a time clock and a card index. He was among the first to emphasize the part that the engineer should play, not only in industry, but in public life. When, therefore, he was called by Mayor Rudolph Blankenburg as Director of Public Works of the City of Philadelphia in 1912 he brought to the task the vision of a city in which not only the things that must be done should be done in the most efficient and creditable way, but in which the application of the common means and effort of a people with an awakened civil consciousness to the making of their city rich, artistic and beautiful, and their communal life helpful, inspiring and enjoyable, should be developed to the utmost. The book is a commentary upon his experience in the office, interspersed with observations suggested by that experience and his study of public management, or drawn from the experiences of other cities; with the views of other publicists, and information, statistical and otherwise, from various sources.

The first chapter, Paving the Way, tells how the interest of the people was aroused, and discusses financial methods, budgets, cost-keeping and appropriations. The abuses attending the jockeying of contracts are described, and the public manner adopted for opening bids illustrated. Ten pages are devoted to an exposé and condemnation of the common practice of levying assessments upon city employees by political parties.

Chapter II considers Some Mechanisms of Municipal Management such as Home Rule for Cities, Municipal Government by Commission, The City Manager, The Ballot (favoring the short variety), Functional Management, Committee Control and Leadership.

Chapter III tells of the application of Scientific Management in City Affairs. The science of management has for its object the development of the one best way in every part of its field, with the emphasis on the "one." In private manufacturing establishments the owner can frequently put into practice means and methods not understood or indorsed by the workers.

Under the title Coöperation the One Best Way, Chapter IV seeks to show that in a city, which is a great industrial plant owned by its citizens collectively, the genuine interest of intelligent citizens, is needed to back up any municipal program. There should also be coöperation between cities, as many of their problems admit of a common solution. The moving of trained municipal employees from city to city in the course of their professional progress, and the rise of the commission manager plan of city administration will hasten this coöperative movement. Standard specifications for contracts and materials are suggested; coöperation between householders, street-cleaning forces, municipal road repair forces, regular contractors' groups and the street-railway company helps in solving the snow-removal problem.

In Chapter V, devoted to the city employee, the means taken to discourage his political activity are described. Uniforming, it is said, generally results in raising the grade of certain classes of employees. Equalization of pay, promotion, pensioning, competitions and welfare work are also touched upon. The author says that even under the civil-service law men can be removed from the public service for the same reasons that they can property be removed from the service of a private company, and tells how he dealt with cases of discharge and discipline.

Although an enthusiastic advocate of the civil service or merit system, Mr. Cooke believes that The Man in Ten Thousand, the man who is best fitted for the larger position, will be found through the personal effort of the appointing officer rather than in the list of eligibles furnished by a civil-service commission. Civil service does very well for positions paying less than $3000 per year, but in his opinion will, as applied to the higher position, take the form of coöperating with the appointing officer in finding the right man, and in fearlessly and exhaustively checking that officer's judgment, rather than in insisting on taking the initiative. He suggests that if the secretaries of the four national engineering societies could be authorized by their several councils to associate themselves as a civil service board to act as an advisory committee to federal, state and municipal civil-service commissions, it would be a decided step in the right direction in filling engineering positions.

Those who know Mr. Cooke through his previous utterances will turn with especial interest to his chapter upon Our Utilities and Their Owners. "If we have good reason," he says, "for speaking without venom and by the facts, we have equally strong incentive for speaking fearlessly. I have already mentioned politics, the juggling of contracts, the absence of expert service and the lack of understanding of the problems of government on the part of the people, as among the causes which retard our progress. But more important than any of these, in my opinion, is the baleful influence constantly wielded directly and indirectly in almost every city in the land by the private-utility interests through their support of the lowest type of political machinery and intrigue."

"The basic fact underlying any discussion of municipal utilities is the essential solidarity of the private interests which control them." What, for want of a better name, he calls "courtesy" precludes the financing of competing interests and the invasion of preëmpted or allotted territory. "Anything like a complete victory for either side in this matter means to the one side wholesale destruction, through public ownership, of certain kinds of paper values, and to the other new and heavy public duties. The present-day managers of a property actually worth hardly $25,000,000, but with outstanding securities of over $50,000,000, are in an exceedingly embarrassing position. They want more than sympathy; they want help."

Methods of financing, and the rôle of the holding company, the efficiency of which the author says, "as a device for the injection of water, compares with the high finance which preceded it as a high-pressure fire main does to a garden hose," are described. Bankers realize that a widespread program of municipal ownership and municipal operation is more or less imminent, and the author has been told by those high in the banking world that the intention is to make these plants yield every possible penny in revenue against the day when ownership will change.

"Where private companies furnish good service at fair rates, give them protection, a free field and a square deal. If they fail in these essentials, any self-respecting city will call the bluff by insisting upon public ownership and public operation."

Confidence in state regulation is on the wane. The work that comes before the public-service commissions is largely engineering, and yet there are almost no engineers on the commissions. The cities are at a disadvantage in obtaining expert testimony in regard to costs and values, as most of the experts have been brought up in the employ of the utilities.

The greatest present-day problem in utility matters is not *who* is to own and operate them, but *how* they are to be operated. A titanic battle is on between a democratic army and eleven billions of capital.

Chapter IX shows how the city can be developed as an ally of industrial progress by attention to its food supply, transportation, public parks and baths, commercial, educational and vocational guidance, the stabilizing of employment, and all those things which make for industrial competency and attract and develop a desirable industrial population.

The citizen must amount to Something More than a Voter. Such organizations as chambers of commerce, city clubs, business men's associations, improvement associations, technical societies, etc., have unlimited possibilities for helping the city.

"In the last analysis," says the author in the concluding chapter, "a city is simply an aggregation of homes, and the object of each individual home is to be the source of the maximum of service and human happiness. Fortunately, it is not necessary to await future developments in order to visualize a beautiful city filled with prosperous folk leading happy and inspiring lives —a 'singing city.'"

FRED R. LOW.

AMERICAN HIGHWAY ENGINEERS' HANDBOOK. Editor-in-chief, Arthur H. Blanchard. First edition. John Wiley and Sons, Inc., New York, 1919. Flexible cloth, 7 x 4 in., 1658 pp., illus., tables. $5.

The task undertaken has been the compilation of a reference book which would include reliable and comprehensive information on all branches of highway engineering and related subjects, including organization and administration of highway departments, financing of improvements, highway design, paving, testing, costs, etc. These questions are discussed in twenty-nine sections, each of which has been edited by an authority. Bibliographies for each section and an extensive index have been provided.

AMERICAN METHODS IN FOREIGN TRADE. A Guide to Export Selling Policy. By George C. Vedder. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 8 x 6 in., 204 pp. $2.

The author of this volume is a believer in the soundness of the distinctively American methods of developing an export trade which have hitherto been adopted by our most efficient world traders. He attempts in this volume to explain how these firms have achieved success and to outline the proper policy to be adopted by those interested in entering foreign markets.

CHILTON TRACTOR INDEX. Published semi-annually by the Chilton Co., Philadelphia, 1919. Paper, 10 x 7 in., 464 pp. $1.

The Tractor Index is a directory of the manufacturers of tractors, tractor parts and accessories, and power farming machinery in the United States. It also includes an illustrated list of American tractors, in which brief specifications for each tractor are given, a table giving complete specifications for 198 tractors, and a similar table of specifications for power farming machinery. A collection of articles on tractors and farm machinery completes the work.

CHLORINATION OF WATER. By Joseph Race. First edition. John Wiley and Sons, Inc., New York, 1918. Cloth, 8 x 5 in., 158 pp. $1.50.

The author has collected and correlated the scattered information in print on the purification of water by chlorine, and presents a systematic account of the theory, practical application and results. Numerous references to the original publications are given.

THE FUNDAMENTAL EQUATIONS OF DYNAMICS. Its Main Coördinate Systems Vectorially Treated and Illustrated from Rigid Dynamics. By Frederick Slate. Berkeley, University of California Press, 1918. Cloth, 8 x 6 in., 233 pp. $2.

The author of this volume feels that the extensiveness of the field of dynamics has necessitated such compression in the general surveys of its principles that the usual treatment leans too heavily on mathematics. His desire has been to prepare a supplement to such standard works which will direct attention to the physical aspects, and to experimental reasoning, by offering a flexible continuation of an elementary stage with unsettled achievement. The book forms Part II of Principles of Mechanics (Part I, Macmillan Co., 1900).

A HANDBOOK OF PHYSICS MEASUREMENTS. Vol. I, Fundamental Measurements, Properties of Matter, and Optics. Vol. II., Vibratory Motion, Sound, Heat, Electricity and Magnetism. By Ervin S. Ferry, in collaboration with O. W. Silvey, G. W. Sherman, Jr., and D. C. Duncan. First edition. John Wiley and Sons, Inc., New York, 1918. Cloth, 8 x 5 in., 233 pp. illus., tables. $2 a volume.

The aim of this work is to furnish the student of pure or applied science with a self-contained manual of the theory and manipulation of those measurements in physics which bear most directly upon his subsequent work in other departments of study and upon his future professional career. The experiments have been selected with regard to the particular determinations now demanded by science and industry and so grouped as to segregate those of value for students of the various branches of engineering.

MAKING THE SMALL SHOP PROFITABLE. By John H. Van Deventer. First edition. Published by the *American Machinist*. (McGraw-Hill Book Co., New York, sole selling agents.) 1918. One-quarter cloth, 12 x 9 in., 113 pp., illus. $1.75.

This book contains a series of articles on important phases of the activities of small machine shops, proper methods of working, cost-keeping, etc., and also illustrations of many handy devices for facilitating work, particularly in shops with limited equipment. It is a continuation of the author's Success in the Small Shop. The articles first appeared in the *American Machinist*.

STEAM ENGINES. Prepared in the Extension Division of the University of Wisconsin, by E. M. Shealy. (Engineering Education Series.) First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 9 x 6 in., 290 pp. 173 illus. $2.50.

This is the third of a series of three textbooks on steam engineering, prepared for correspondence students in the University of Wisconsin Extension Division. The aim in this volume is to teach the fundamental principles underlying the operation of the steam engine, in as simple and non-mathematical a manner as possible. Particular attention is given to valve gears.

LOCOMOTIVE HAND-BOOK. Compiled by American Locomotive Company, New York, 1917. Leather, 4 x 6 in., 195 pp., 9 illus., 89 tab. $0.75.

The compilers have arranged the tables, formulæ and other information used by locomotive designers, in a convenient book of pocket size.

OXWELDING AND CUTTING. Manual of Instruction. Compiled by the Oxweld Acetylene Company, Jersey City, N. J. First edition. (copyright 1918). Paper, 5 x 8 in., 124 pp., illus. $0.50.

The manual describes the apparatus, the methods of using it and gives a series of practice problems illustrating correct methods of meeting those that occur in shops where oxy-acetylene is used for cutting and welding.

PRACTICAL AVIATION. An Understandable Presentation of Interesting and Essential Facts in Aeronautical Science. By Charles B. Hayward. Second edition. American Technical Society. Chicago, 1919. Flexible cloth, 6 x 8 in., 784 pp., illus. $3.75.

This volume treats of the theory, design and construction of airplanes and dirigible balloons, and their motors; and describes the types in use. Considerable space is given to the military uses of airplanes and to the methods of flying used by military aviators.

PRACTICAL AVIATION FOR MILITARY AIRMEN. By Major J. Andrew White. Wireless Press, New York. (copyright 1918). Cloth, 6 x 9 in., 197 pp., illus., pl. $1.75.

The author's aim has been to produce a textbook suited for intensive study by students of military aviation who wish to learn the essentials of flying in the shortest possible time. The reading matter has been condensed by eliminating everything but essentials, and providing a large number of drawings, conveniently arranged.

SCRAP METALS. Study of Iron and Steel Old Material, Its Preparation and Markets. By George H. Manlove. The Old Metals, by Charles Vickers. The Penton Publishing Co., Cleveland, 1918. Cloth, 6 x 8 in., 278 pp. $2.

The two monographs which compose this volume treat of the utilization of old metal. The first is restricted to scrap iron and steel, while the second discusses non-ferrous metals. The book is a pioneer attempt to present the scrap industry in print.

TOPOGRAPHIC STADIA SURVEYING. A Manual with Reduction Tables and a new Type of Reduction Diagram. By C. E. Grunsky. D. Van Nostrand Co., New York, 1917. Cloth, 4 x 7 in., 99 pp., 18 illus., 8 tab., folding diag. in cover pocket. $2.

The author describes a method of surveying and a special type of diagram for the reduction of stadia notes, which has been found to be very satisfactory in practice.

THE ENGINEERING INDEX

Published Monthly by The American Society of Mechanical Engineers

The Engineering Index was Founded in 1884 by the Association of Engineering Societies; Published from 1895 to 1919 by The Engineering Magazine Company; and Acquired January 1919 by The American Society of Mechanical Engineers

THE following pages form a descriptive Index to articles on engineering and related subjects in current periodicals. In its preparation the Society's engineering staff regularly examines all of the technical journals and society publications received by the Engineering Societies Library, which form one of the greatest and most complete collections of scientific periodicals in the world, comprising upward of 1100 distinct publications in some ten languages. Cross-references are freely introduced in the Index, and in all cases where the titles of articles are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC COPIES OF ARTICLES LISTED

THE Society is prepared to supply photostatic copies (white printing on brown background) of any of the articles listed. Copies of the periodicals themselves, or clippings of articles, cannot be supplied.

Price of each print (up to 11 x 14 in. in size), 25 cents plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Those holding coupon books for clippings formerly issued by The Engineering Magazine Company may use the coupons in payment for photostatic prints. In ordering, state plainly

(1) Page number of Index on which item appears
(2) Title of article
(3) Name of periodical.

Orders should be sent to

Harrison W. Craver, *Director,*
Engineering Societies Library,
29 West 39th Street, New York City.

Mechanical Engineering

AIR MACHINERY

Air Pumps

Air Ejectors (Les éjecteurs extracteurs d'air), L. Congé. Revue Générale de l'Electricité, vol. 4, no. 17, Oct. 26, 1918, pp. 629-632, 6 figs. Details of Westinghouse-Leblanc air pump, of Breguet ejector and of British Westinghouse apparatus.

See also MECHANICAL ENGINEERING, Heating and Ventilation (Air Cooling)

CORROSION

Wire Ropes

Interior Corrosion of Wire Ropes, Wm. Fleet Robertson. Can. Min. Jl., vol. 40, no. 1, Jan. 8, 1919, pp. 6-7. Report of tests undertaken on rope which broke, it is said, by oxidizing of wires, chiefly internally, caused by action of corrosive water and a humid atmosphere.

FORGING

Drop Hammers

4-ton Drop Hammer at Crewe Works. Engineering, vol. 106, no. 2765, Dec. 27, 1918, pp. 736-737, 7 figs. Description with illustrations of the hammer and some of its work. Its development and the necessary equipment.

European Situation

Some Drop Forge Possibilities Abroad, L. W. Alwyn-Schmidt. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 471-473. Review of present conditions; situation in foreign countries; methods of procuring business in Europe.

Forge-Shop Capacity

Selecting a Source of Supply for Forgings, W. F. Rockwell. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 1-3. Convenience of enlarging forge-shop capacity; preference of buyers to order forgings by sets.

Forge Shop

Pan Motor Forge Shop About Completed. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 490-492. Details of layout and equipment; methods for handling raw and finished material. Shop to be largest in U. S.

A Progressive Forge Shop in Rockford. Am. Drop Forger, vol 4, no. 12, Dec. 1918, pp. 480-481, 6 figs. Equipment and general layout of departments.

Modern Forge Shop at the Essington Plant. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 474-475, 3 figs. General description of works turning out marine equipment. Layout of shops allows for future expansion.

Forging Industry

A Review of the Drop Forging Industry, A. W. Peterson. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 36-38, 2 figs. Data showing production development of forging industry over period of 35 years; importance of forging industry during years of war.

Furnaces

Heating and Preheating Forging Furnaces. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 57-59, 4 figs. Recent installation designed to withstand distorting action of heat as well as wear. Combustion chambers on preheating furnace are staggered on each side.

Historical Data

Historical Data on Hammers and Forgings, Howard Terhune. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 39-41. Review of improvements since issue of first patent in 1842; introduction of principle of modern board drop hammer in 1861; present tendencies.

See also ELECTRICAL ENGINEERING, Furnaces.

FOUNDRIES

Brass Foundries

Materials and Chemicals Used in Brass Foundry Practice, Charles Vickers. Brass World, vol. 14, no. 12, Dec. 1918, pp. 343-345. Deals with history, properties, appearance, physiological action and commercial use of substances commonly used in brass founding. First of series of articles.

Casting Methods

Molding and Pouring a Gasoline Engine Bed, F. H. Bell. Can. Machy., vol. 21, no. 5, Jan. 30, 1919, pp. 106-108, 4 figs. Shows method of casting a sheet-steel bottom into a gray-iron casting, making entire bed into a tank.

Core Ovens

The Application of Pyrometers to Core Ovens, G. W. Keller. Foundry, vol. 47, no. 318, Feb. 1919, pp. 72-74, 3 figs. From a paper before Am. Foundrymen's Assn.

Furnace, Electric

The Electric Furnace in the Grey Iron Foundry, F. H. Bell. Can. Machy., vol. 21, no. 1, Jan. 2, 1919, pp. 7-8, 4 figs. Practicability of melting gray iron for foundry purposes by electricity; process followed at Bowmanville Foundry Co.

Irons

Conversion of White Iron into Foundry, C. T. Huang. Iron Age, vol. 103, no. 4, Jan. 23, 1919, pp. 231-232. How Chinese native irons may be made available as a means of relieving the scarcity of other grades in that country.

Molding

Molding Shoes for Caterpillar Tractors. Iron Age, vol. 103, no. 2, Jan. 9, 1919, pp. 119-120, 3 figs. Davenport molding machine with hurriedly devised handling rigging gives satisfactory results; 1000 shoes made per day.

Patterns

The Laying Out of Patterns, Joseph A. Shelly. Machy., vol. 25, no. 6, Feb. 1919, pp. 493-497, 12 figs. Methods of making the drawings or layouts that are required by the patternmaker in planning his work, together with allowances necessary for draft and shrinkage and for machining castings in the shop.

Steel Castings on Pacific Coast

Steel Castings on the Pacific Coast. Iron Age, vol. 103, no. 4, Jan. 23, 1919, pp. 233-235, 2 figs. Growth of industry due to the war; good steel made without pig iron; overcoming manufacturing difficulties.

Tumbling Barrels

Tumbling Barrels in Foundries (Scheurfaesser und Putztrommeln in Giessereibetrieben), Rauch und Staub, vol. 8, no. 12, Sept. 1918, pp. 113-114. General discussion on construction, use and advantages of tumbling barrels for changing castings. States that castings up to 45 in. long and weighing 2000 lbs. can be cleaned in suitable revolving drums. Describes inclined drums 36 ft. long, 28 in. in diameter.

See also MARINE ENGINEERING, Ships (Castings); ELECTRICAL ENGINEERING, Furnaces.

FUELS AND FIRING

Argentine

Fuels in Argentine (Die Brennstoffe Argentinens), Rauch und Staub, vol. 8, no. 12, Sept. 1918, pp. 114-115. General discussion on the fuel situation in Argentina, abstracted from Berichte ueber Handel und Industrie, vol. 23, no. 4, Feb. 1918.

Ash

Fusibility of West Virginia Coal Ash, Walter Selvig. Coal Age, vol. 15, no. 1, Jan. 2, 1919, pp. 12-16, 2 figs. Method of preparing ash for fusion test and determining initial softening temperature and interval of fusion. Includes a tabulation of tests on West Virginia coals.

Bagasse

Bagasse Feeders, Furnace Design and Furnace Control, A. Gartley. La. Planter, vol. 62, no. 21, Jan. 11, 1919, pp. 25-28, 5 figs. Suggestions on design; curves giving pounds of water which can be evaporated per pound of bagasse having different percentages of moisture. Paper before Hawaiian Sugar Planters' Assn.

Briquets

Some Notes on the Manufacture of Fuel Briquettes, E. H. Robertson. Trans. Min. & Geol. Inst. India, vol. 13, pt. 1, Sept. 1918, pp. 49-61, 6 figs. Analysis of manufacturing methods; results obtained by some experimenters; examples of survivance of briquettes.

The Economy of Briquetting Small Coal, J. A. Yeadon. Tran. Min. Inst. Scotland, vol. 40, pt. 7, 1918-1919, pp. 145-148 and (discussion) pp. 148-150. Gain in calorific power by briquetting with pitch as agglomerant; rectangular and "ovoid" forms of briquettes.

Coal Selection

Selecting Coal for Power Plant Use, Robert June. Elec. Rev., vol. 74, no. 3, Jan. 18, 1919, pp. 94-97, 4 figs. Characteristics of various coals; influence of coal upon furnace-chamber design; purchase of coal. (First of series on power-plant management.)

Clay Products, Burning

Fuel Economy in Clay Products Burning—III, A. V. Bleininger and A. F. Greaves Walker. Can. Mfr., vol. 39, no. 1, Jan. 1919, pp. 87-88. Means of controlling burning.

Conservation

Fuel Conservation, Robert Collett. New England R.R. Club, Dec. 10, 1918, pp. 190-208. Waste of fuel by reason of engines delayed on road and by engines kept under steam unnecessarily at terminals; improper handling of engines; excessive firing; engines not in good condition; fuel not up to contract specification.

The Threatened Coal Shortage and the Possible Methods of Economising Fuel—II, John B. C. Kershaw. Cassier's Eng. Monthly, vol. 54, no. 6, Dec. 1918, pp. 308-315, 2 figs. Applicability of remedies proposed in October issue to English conditions; recommendations of U. S. Fuel Administration; coal-dust firing as an aid to fuel conservation.

Fuel Economy Will Continue a Serious Problem, W. A. Shoudy. Elec. World, vol. 73, no 1, Jan. 4, 1919, pp. 14-16, 3 figs. Can be improved by proper application of correctly designed apparatus maintaining high vacuum, eliminating small wastes and not operating too many boilers; other suggestions.

Draft

Saving the Waste in the Chimney—III, Robert Sibley and Chas. H. Delany. Jl. Elec., vol. 42, no. 2, Jan. 15, 1919, pp. 79-80, 1 fig. Determination of actual draft required for different fuels. Chart showing lb. of coal burned per sq. ft. grate surface per hr. against draft between furnace and ash pit in in. of water.

Steam Plant Efficiency. Coal Trade Jl., year 51, no. 2, Jan. 8, 1919, pp. 37-38, 4 figs. Relation between kinds of coal and completeness of combustion for six sets of conditions; gaging air supply for given furnace and fuel. (Concluded.)

Fuel Requirements for Factories

Fuel Requirements for Factories, Charles L. Hubbard. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 125-126. How to make tests of fuel requirements for extremes of weather, calculate needs for other conditions and outside temperatures, and estimate amount of fuel needed month by month throughout heating season.

Gas

Uses Gas in Twenty-One Manufacturing Processes, F. M. Lester. Gas Age, vol. 43, no. 2, Jan. 15, 1919, pp. 102-104, 6 figs. How gas is used in plant manufacturing gasoline motors and railway supplies and consuming 10,000,000 cu. ft. gas per month.

Gas Fuels

See Producer Gas below; items under INDUSTRIAL TECHNOLOGY; and Coal and Coke (Coke-Oven Gas) and Oil and Gas, under MINING ENGINEERING.

Heat Value, Determination of

Use of the Hydrogen-Volatile-Matter Ratio in Obtaining the Net Heating Value of American Coals, A. C. Fieldner and W. A. Selvig. Department of Interior, Bur. of Mines, tech. paper 197, 13 pp. 4 figs. Curves, constructed from 2000 analyses, showing relation between percentages of hydrogen and volatile matter of different coals.

Calorific Valuation of Coal Without a Calorimeter, Proctor Smith. Cassier's Eng. Monthly, vol. 54, no. 6, Dec. 1918, pp. 333-334. Approximate analysis by Goutal's formula.

Indiana Coals

Getting Better Combustion of Indiana Coals, T. A. Marsh. Elec. World, vol. 73, no. 2, Jan. 11, 1919, pp. 72-74, 7 figs. Practical methods by means of which furnace equipment installed years ago can be made to produce results comparable with good modern practice.

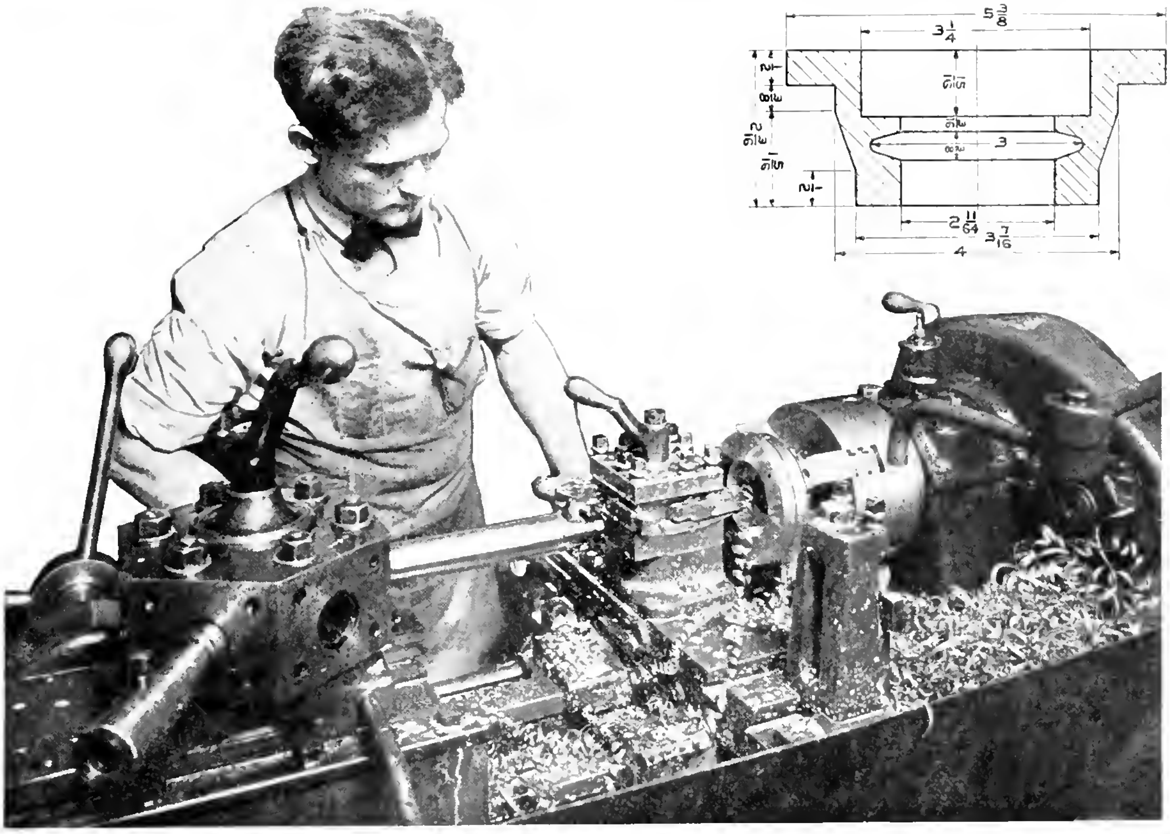
Lignites

Combustion of Lignite and High-Moisture Fuels, T. A. Marsh. Elec. World, vol. 73, no. 6, Feb. 8, 1919, pp. 265-267, 5 figs. Typical analyses of high-moisture fuels in the United States and Canada and summary of experience derived from burning fuels of the kinds described in power plants.

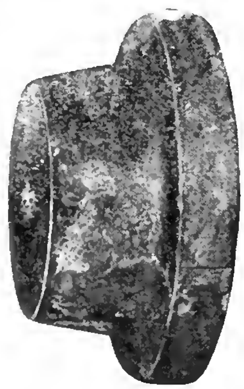
Notes on Lignite, S. M. Darling. Power Plant Eng., vol. 23, no. 3, Feb. 1, 1919, pp. 148-150. Characteristics and utilization. Abstract of Technical Paper 178, Bureau of Mines.

Motor Fuel

The Motor Fuel Problem, W. R. Ormandy. Colliery Guardian, vol. 116, no. 3021, Nov. 22, 1918, pp. 1076-1077. From paper before Instn. of Petroleum Technologists.



Value of the Square Turret



THIS shows the amount of material removed and how well the many operations on these tough power sprocket clutches were finished on the No. 4 Universal Screw Machine. The hexagon turret was used only for boring. The square turret, loaded to capacity with cutters, did the rest with the aid of its eight power cross and longitudinal feeds.

For Work too Complicated for Ordinary Screw Machines

The special features of the No. 4 Universal (in this case the unusual use for the square turret) adapt them to a wide range of work too complicated for ordinary screw machines or turret lathes.

SEND FOR DETAILS

Turret Lathes and Screw Machines
from 5/8 in. x 4 in. to 4½ in. x 44 in., Maximum Swing 21½ in.

THE WARNER & SWASEY COMPANY

CLEVELAND, OHIO, U. S. A.

NEW YORK Office—Singer Building. **Boston Office**—Oliver Building. **Buffalo Office**—Iroquois Building. **Detroit Office**—Ford Building. **Chicago Office and Show Rooms**—618-622 Washington Blvd.
FOREIGN AGENTS: Chas. Churchill & Co., Ltd., London, Birmingham, Manchester, Newcastle-on-Tyne and Glasgow. Allied Machinery Company, Paris and Turin. Van Rietschoten & Houwens, Rotterdam. Yamatake & Co., Tokio. Benson Brothers, Sydney and Melbourne. A. Asher Smith, Sydney. A. R. Williams Machinery Co., Ltd., Toronto, St. John, Winnipeg and Vancouver. Williams & Wilson, Ltd., Montreal.

Peat

Peat and the Electrical Industry (La tourbe et l'industrie électrique), Pierre Gieu. Revue Générale de l'Electricité, vol. 4, no. 22, Nov. 30, 1918, pp. 843-851, 3 figs. Artificial drying and gasification of peat; effects of humidity on its calorific value; permissible percentage of humidity. Results of an extended investigation undertaken under the direction of Minister of Mines, Canada.

Peat in 1917, C. C. Osborn. Department of Interior, U. S. Geol. Survey, Mineral Resources of the United States—Part II, Dec. 19, 1918, pp. 257-283, 1 fig. General conditions of peat industry; occurrence, properties and uses of peat; peat industry in principal foreign countries; selected bibliography; map of U. S. showing principal peat deposits.

Powdered Fuel

Progress Realized During the War in the Utilization of Fuels (Progrès réalizés pendant la guerre dans l'utilisation des combustibles), E. Damour. Industrie Electrique, year 28, no. 637, Jan. 10, 1919, pp. 5-7. Gasification and pulverization of fuels. From extensive account in Chemie et Industrie.

Powdered Coal Advance and Development, H. A. Kimber. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 67-68. Use of powdered fuel for steam generation; improvements in distribution; control of fuel; summary of furnaces for which pulverized coal was installed during 1918.

A Review on the Use of Powdered Coal, W. O. Renkin. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 22-25, 3 figs. Early uses and present methods; comparative data on fuels.

Suggestions for Burning Pulverized Coal, W. G. Wilcox. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 492-494. Control of combustible and air in burning pulverized coal; method of projecting coal in suspended form into furnace; importance of mixing coal dust properly.

Stokers

Fuel Burning Equipment of Modern Power Stations, Joseph G. Worker. Elec. Jl., vol 16, no. 2, Feb. 1919, pp. 55-60, 15 figs. Examples of various installations using underfeed stokers, auxiliary equipment to control their operation.

Mechanical Stokers—II, Robert June. Brick & Clay Rec., vol. 53, no. 14, Dec. 31, 1918, pp. 1147-1149, 3 figs. Concludes from examination of various types that chain-grate stoker is suitable for boilers of good size up to 250 per cent rating and overfeed stoker for medium-sized installations up to 200 per cent rating.

Waste Heat, Utilization of

Utilization of Waste Heat at Municipal Gas Works of Tuebingen (Die Abhitzegewinnung und verwertung im staedt. Gaswerk Tuebingen), Henig. Journal fuer Gasbeleuchtung, vol. 61, no. 45, Nov. 9, 1918, pp. 529-534, 1 fig. History and performance of rational waste-heat system utilized for heating water for distant municipal bath. Tests. Costs.

Steam Raising with Waste Heat from Coal- and Oil-Fired Furnaces, Iron & Coal Trades Rev., vol. 97, no. 2648, Nov. 22, 1918, pp. 580, 4 figs. Description of standard heat-raising unit (Brett system), embodying coal-fired furnace with boiler.

See also MINING ENGINEERING, Coal and Coke (Coal Oxidation and Ignition); MECHANICAL ENGINEERING, Motor-Car Engineering (Fuels), Power Plants (Low-Grade Fuels)

GAGES

Profile Gages

Grinding Accurate Profile Gages by Means of Master Plates, Herbert M. Darling. Am. Mach., vol. 50, no. 3, Jan. 16, 1919, pp. 105-106, 3 figs. Description of operation.

Thread and Wing Gages

Thread Gages; Wing Gages, Erik Oberg. Machy., vol. 25, no. 6, February, 1919, pp. 502-506, 13 figs. Last of a series of articles describing principles involved and procedure followed by the Pratt & Whitney Company in developing gaging systems for interchangeable manufacture.

The Precision Measurement of Thread Gages. Can. Machy., vol. 21, no. 5, Jan. 30, 1919, pp. 113-115, 4 figs. Commercial equipment manufactured by Arthur Knapp Eng. Corporation after models developed by Bur. of Standards.

HANDLING OF MATERIALS

Ash Handling

Bennis Ash Handling Plant. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 84-85, 3 figs. Pneumatic ash plant; steam suction conveyors, ash elevators and ash hoists.

Coal Handling

Coal Handling at Ports, H. Hubert. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 42-45, 6 figs. An account of a number of modern plants for dealing with coal at ports.

Coal-Handling Appliances at the Coventry Electricity Works, George Frederick Zimmer. Engineering, vol. 107, no. 2767, Jan. 10, 1919, pp. 37-42, 27 figs. Drawings, general data and description of the plant.

Coal Tipple and Washery at Lehigh, Mont., E. P. Stewart. Coal Age, vol. 15, no. 1, Jan. 2, 1919, pp. 9-11, 4 figs. Apparatus designed to clean coal thoroughly and prepare locomotive fuel.

Coal Handling Plant at Sewall's Point, Virginia. Power, vol. 49, no. 2, Jan. 14, 1919, pp. 54-56, 5 figs. Description of new facilities of Virginia Railway at coal pier near Norfolk, Va. From Coal Age.

Coke

The Mechanical Handling of Coke, Alwyne Meade. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 57-61, 8 figs. The problems involved; description of conveyors designed to overcome difficulties; aspects of cost.

Explosives

Munition Handling Devices. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 73-75, 5 figs. A few examples in which well-known types of conveying apparatus are modified to serve specific purposes in the manufacture of explosives.

Gravity Roller Runway

The Gravity Roller Runway, George Frederick Zimmer. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 33-41, 28 figs. The component parts of gravity roller runways; accessory plant such as shoots, "humpers," stackers and "gadgets."

Mechanical Handling

The Mechanical Handling of Materials, Percy G. Donald. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 29-32, 8 figs. After discussing objections to mechanical handling, the author deals with such plant as an investment, the speed that is desirable, the importance of a suitable layout, and finally indicates the various types of plant that are available.

Paper Mill

Material Handling in a Paper Mill, Henry J. Edsall. Indus. Management, vol. 57, no. 2, Feb. 1919, pp 97-103, 18 figs. Labor-saving equipment of Dill & Collins Co. (To be continued.)

Pneumatic Handling of Cereals

Pneumatic Handling of Cereals, C. Bentham. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 61-67, 15 figs. Importance of pneumatic systems in unloading ships; types of plant in operation; the exhauster; problems involved in the design of a suitable nozzle.

Portable Pneumatic Grain Unloading Plant. Conveying, Cassier's Eng. Monthly Supp., vol. 1, no. 7, Dec. 1918, pp. lxxxiii-lxxxvi, 4 figs. Equipment includes 6-cylinder Aster petrol engine of 85 hp. with rotary blower, mounted on 4-wheeled, 25-ton railway truck.

HEAT TREATING

Developments in 1918

1918 Developments in Heat Treating, James H. Herron. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 53-54. Changes in methods used for heat-treating materials; scope of heat-treating activities.

Furnaces

Heating Furnaces and Annealing Furnaces—II. W. Trinks. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 69-72 and 80, 7 figs. Design, operation and construction. Furnace capacity; rate of heat transfer; temperature to which metal is to be heated.

Malleable Iron

Reducing the Malleable Iron Annealing Period, A. E. White and R. S. Archur. Foundry, vol. 47, no. 318, Feb. 1919, pp. 61-65, 12 figs. Report of an investigation made at the University of Michigan. From a paper before the American Foundrymen's Assn.

Steel for Motors

Treatments of Steels Used in the Construction of Light-Weight Engines. (Emplois et traitments des aciers utilisés dans la construction des moteurs légers), M. L. Barbillon. Bulletin Technique de la Suisse Romande, year 44, nos. 15 and 17, July 27 and Aug. 24, 1918, pp. 140-142 and 158-160, 4 figs. July 27: Steel employed for shafts, nuts, bolts and cams. Aug. 24: Soft carbon steels; chrome-nickel steels; nickel steels; tungsten steels; special steel having 0.20C + 0.13 Si + 0.36 mn. — 12 Ni.

Lincoln Motor Co.'s Heat Treating Plant, F. L. Prentiss. Iron Age, vol. 103, no. 2, Jan. 9, 1919, pp. 107-111, 7 figs. Department equipped for quantity production in plant designed for changing from airplane to commercial motor work.

See also METALLURGY, Iron and Steel (Heat Treatment)

HEATING AND VENTILATION

Air Cooling

Special Applications of Small Air-Cooling Systems. Heat. & Vent. Mag., vol. 16, no. 1, Jan. 1919, pp. 43-46, 4 figs. Arrangements with forced and gravity circulation of air.

Boiler Rating

Heating Versus Power Boiler Rating, P. J. Dougherty. Power, vol. 49, no. 3, Jan. 21, 1919 pp. 84-85. Showing why rules in general used for determining and comparing rating or capacity of high-pressure boilers are not applicable to low-pressure or so-called heating boilers.

Central-Station Heating

Central Station Heating; Its Economic Features with Reference to Community Service, John C. White. Department of Interior, Bur. of Mines, tech. paper 191, 23 pp., 6 figs. Data on costs and results obtained with central heating stations.

Factory Heating

Modern Factory Heating, Alfred G. King. Domestic Eng., vol. 86, nos. 1 and 2, Jan. 4, 11, 1919, pp. 27-30 and 76-79, 11 figs. Requirements for factory heating; construction details.

Tunnel Ventilation

The Ventilation of Tunnels and Buildings, Francis Fox. Universal Engr., vol. 28, no. 6, Dec. 1918, pp. 40-46. Ventilation systems in operation at several European tunnels; prescribed hygienic practice concerning renovation of air in dwellings.

Ventilation Plant for Simplon Tunnel (Die Ventilationsanlage des Simplon Tunnels), F. Rothpletz. Schweizerische Bauzeitung, vol. 73, no. 1, Jan. 4, 1919, pp. 3-4, 3 figs. Remodeling and enlarging of the ventilation system, located at the north entrance only of the twin-tunnel, operated electrically. Southward air current chosen to avoid rusting of structural steel due to condensation if southern air were sent northward. Total air volume 180 cu. m. per sec. at velocity in tunnel of 3 to 4 m. per sec. Part 1.

Two-Pipe System

Care of Heating and Ventilating Equipment, Harold L. Alt. Power, vol. 49, no. 5, Feb. 4, 1919, pp. 156-159, 14 figs. A discussion of the two-pipe system. Seventh article.

Vapor Heating

Modern Practice in Vapor Heating. Heat. & Vent. Mag., vol. 16, no. 1, Jan. 1919, pp. 48-52, 6 figs. The Broomell system.

See also MARINE ENGINEERING, Ships (Ventilating and Heating)

HOISTING AND CONVEYING

Conveyor Types

Conveyors for Engineering Works. Engineer, vol. 126, no. 3283, Nov. 29, 1918, pp. 462, 3 figs. Deals with types in use in engineering works, such as conveyors for rapid assembly of motors, case elevators, and shell conveyors. (From paper before Manchester Assn. of Engrs., by W. H. Atherton.)

Design

Some Details of Conveyors and Elevators, W. H. Atherton. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 46-49, 20 figs. Design of a number of essential details in conveyors and elevators, dealing with chains, sprocket wheels, buckets, skidders, frames and bearings.

Design of Electrically-Driven Lifting Blocks. Elecn., vol. 81, no. 2115, Nov. 29, 1918, pp. 639-640, 7 figs. Abstract of article in Elektrotechnische Zeitschrift, No. 1, 1918.

Electric Haulage

Notes on Three-Phase Electric Haulage Equipment, L. Fokes. Colliery Guardian, vol. 116, no. 3025, Dec. 20, 1918, pp. 1295-1296, 5 figs. Haulage room; motor; slip rings and brush gear; control equipment; isolating switch; reversing switch; controller; resistances; liquid resistance.

History

History of Conveying—II, George Frederick Zimmer. Conveying, Cassier's Eng. Monthly Supp., vol. 1, no. 7, Dec. 1918, pp. lxxv-lvvvii, 9 figs. Bucket elevators; elevator and conveyor chains. (Continued.)

Trucks

See Transportation, under ORGANIZATION AND MANAGEMENT.

Wire Rope

The Wire Rope and Its Uses for Conveying Purposes. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 77-79. General principles: single and double ropeway systems; single fixed rope system.

HYDRAULIC MACHINERY

Hydraulic Plants

Extension to the Ontario Power Co.'s Plant, Thos. H. Hogg. Can. Engr., vol. 36, no. 3, Jan. 16, 1919, pp. 139-144 and 149-151, 23 figs. Construction of 13 miles of 13.5-ft. diameter wood-stave pipe for 50,000-hp. capacity; steel differential surge tank, 60 ft. in diameter, 94 ft. high; installation of two 20,000-hp. turbines with direct-connected generators.

Turbines

Banki's New Hydraulic Turbine (Neue Wasserturbine von Donat Banki, Professor in Budapest). Schweiz. Bauzeitung, vol. 72, no. 24, Dec. 14, 1918, pp. 235-236, 4 figs. The new turbine fills the gap between the Pelton wheel and the Francis turbine. Very compact.

New 2500-Hp. Turbine in the Kubel Hydroelectric Power House, near Saint Gall, Switzerland (La nouvelle turbine de 2500 ch. de l'usine hydro-electrique de Kubel pres Saint-Gall Suisse). Revue Generale de l'Electricite, vol. 5, no. 1, Jan. 4, 1919, pp. 19-25, 9 figs. Results of trials of compact design of turbine with overhanging rotor to determine output, regulation and efficiency. Description of new regulator.

Turbine Operation

Economical Operation of Hydraulic Turbines, E. A. Gibbs. Can. Engr., vol. 36, no. 2, Jan. 9, 1919, pp. 127-128. Cleanliness, care and upkeep important factors in obtaining maximum efficiency. Also abstracted in Elec. World, vol. 73, no. 1, Jan. 4, 1919, pp. 25-26.

Turbine Tests

Standard Testing Code for Hydraulic Turbines, F. H. Rogers. Elec. Wld., vol. 73, no. 4, Jan. 25, 1919, pp. 164-166. Engineering societies are urged to adopt code of Machinery Builders' Society.

Water Hammer

Charts for Calculating Water Hammer. Jl. Elec., vol. 42, no. 2, Jan. 15, 1919, pp. 74-75, 2 figs. Constructed to give maximum possible rise or fall in pressure due to water hammer as determined from $h = a V/g$, a being velocity of wave (in an additional diagram) and V velocity of flow in pipe.

See also MECHANICAL ENGINEERING, *Power Generation (Tides)*

INTERNAL-COMBUSTION ENGINES

Design

Port Design for Two-Cycle Oil Engines, D. O. Barrett. Gas Engine, vol. 21, no. 2, Feb. 1919, pp. 37-42. Description of some types of two-cycle engines; formulae for inlet, transfer and exhaust ports.

Oil Engines

The High-Compression Oil Engine, W. G. Gernandt. Jl. Soc. Automotive Engrs., vol. 4, no. 2, Feb. 1919, pp. 112-117 and discussion, pp. 117-118.

Internal Combustion Engine Development. Eng. Rev., vol. 32, no. 6, Dec. 16, 1918, pp. 164-166, 8 figs. Piston designs; leading particulars of engines developing 80 hp. per cylinder. (Concluded.)

LUBRICATION

Motor-Cylinder Lubrication

Motor-Cylinder Lubrication, G. S. Bryan. Universal Engr., vol. 28, no. 4, Oct. 1918, pp. 37-45, 1 fig. Study of conditions under which lubrication takes place and of characteristics of motor-cylinder oils that determine their suitability for these conditions.

See also RAILROAD ENGINEERING, *Locomotives (Lubricators)*; MECHANICAL ENGINEERING, *Motor Car Engineering (Lubrication)*

MACHINE ELEMENTS AND DESIGN

Ball Bearings

Why Do Ball Bearings Sometimes Fail? F. J. Jarosch. Am. Mach., vol. 50, no. 5, Jan. 30, 1919, pp. 209-213, 23 figs. An analysis of failures arising from poor selection and mistreatment.

Floating-Frame Reduction Gear

The Design and Progress of the Floating-Frame Reduction Gear, John H. Macalpine. Proc. Engrs., Soc. Western Pa., vol. 34, no. 7, Oct. 1918, pp. 519-535. Discussion. (Continued from Proc. Feb. 1918, p. 71.) Discussor contends rigid-frame gears are running continuously, with equally high tooth pressures, at the same speeds as floating-frame gears.

Machine Design

Developing Designs for Machinery and Tools, F. E. Johnson. Machy., vol. 25, no. 6, Feb. 1919, pp. 517-518, 5 figs. Cost of designing a new machine; evolution of design of a specific machine; overcoming defects in original design.

Screws

Optical Projection for Screw-Thread Inspection, James Hartness. Mech. Eng., vol. 41, no. 2, Feb. 1919, pp. 127-135, 10 figs. Analysis of screw-thread elements essential to strength and dependability; description of method for their accurate inspection.

Determination of Screw Dimensions (Détermination des dimensions à donner aux vis). La Métallurgie, year 51, no. 1, Jan. 1, 1919, pp. 21-23. Formulæ in three cases: (1) when screw is subject to tension and compression, (2) when screw is subjected to tension or compression by motion of nut, (3) when subjected to shear.

MACHINE SHOP

Die Making

The question of Our Die Room Equipment. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 26-32, 23 figs. Improvements in die-room practices during years of war; suggestions to executives in regard to selecting equipment.

Grinding

Abrasives for Grinding Malleable Castings, W. T. Montague. Foundry, vol. 47, no. 318, Feb. 1919, pp. 74-75. Adapted from a recent publication of the Norton Co.

Machine Shops

Westinghouse Marine Engineering Works, Edward K. Hammond. Machy., vol. 25, no. 6, February, 1919, pp. 538-544, 12 figs. Description of a new plant at South Philadelphia for manufacturing the Westinghouse Marine System.

Milling Cutters

How Milling Cutters Are Made, F. B. Jacobs. Iron Trade Rev., vol. 64, no. 2, Jan. 9, 1919, pp. 150-154, 14 figs. How quantity production is secured by modern standard machinery and careful routing of work.

Some Milling Applications and Adaptations. Engineer, vol. 127, no. 3288, Jan. 3, 1919, pp. 6-9, 22 figs. Description of the development and use of the Francis milling cutter in munitions work.

Repair Shop

Camp Holabird Motor Truck Repair Shops. Jl. Soc. Automotive Engrs., vol. 4, no. 2, Feb. 1919, pp. 86-87. Repair shop procedure. Shop does 80 per cent of repair work required by Army trucks.

Tool Casting

Casting Tools from an Air-Hardening Steel. Foundry, vol. 47, no. 318, Feb. 1919, pp. 66-67, 3 figs. New alloy used successfully in the manufacture of dies and forming tools without forging; tungsten not present in the metal.

Tool Making

The Alfred Herbert Machine Tool Shop. Cassier's Eng. Monthly, vol. 54, no. 6, Dec. 1918, pp. 325-332, 8 figs. Facts about British key industries. (Second article.)

Machine Shop Economies. Universal Engr., vol. 28, no. 6, Dec. 1918, pp. 35-39. Manufacture of jigs and special tools; possible economy in selecting speeds and feeds.

See also MECHANICAL ENGINEERING, *Mechanical Processes (Dies)*

MACHINERY, METAL-WORKING

Boring Machine

Cylinder Boring and Reaming Tools, Franklin D. Jones. Machy., vol. 25, no. 6, Feb. 1919, pp. 507-515, 26 figs. Types and designs of cutter heads used for rough-boring and reaming small engine cylinders.

Boring Mill for Precision Work. Iron Trade Rev., vol. 64, no. 2, Jan. 9, 1919, pp. 156-157, 3 figs. Base and column of horizontal boring machine are heavily ribbed and metal distributed to reduce vibration. Operating mechanism is provided with ball thrust bearings.

Drilling Machine

The Hill Multiple-Spindle Drilling Machine. Am. Mach., vol. 50, no. 5, Jan. 30, 1919, pp. 189-190, 2 figs. Spindle drive design permits of close spacing of the drilling heads with a simple mechanism.

Lathes

The Bullard 8-Inch Mult-Au-Matic. Am. Mach., vol. 50, no. 5, Feb. 6, 1919, pp. 236-241, 6 figs. A detailed description of the machine.

Marking Machine

Making Milling and Gear Cutting Attachment—II, Robert Mawson. Can. Machy., vol. 21, no. 4, Jan. 23, 1919, pp. 78-81, 11 figs. Tools and methods used by Presto Machine Co., with special reference to marking machine for graduating dividing head base.

Milling Machines

Making Milling and Gear Cutting Attachment—III, Robert Mawson. Can. Machy., vol. 21, no. 5, Jan. 30, 1919, pp. 97-100, 15 figs. Tools and methods followed when machining vertical slide column base, dividing head, index bearing and plates of attachment.

Building the Kempsmith Milling Machine, M. E. Hoag. Am. Mach., vol. 50, nos. 3 and 5, Jan. 16 and 30, 1919, pp. 101-104 and 195-198, 23 figs. Description of some of operations followed in construction of milling machines.

MACHINERY, WOODWORKING

Felling Trees, Machine

Machine for Felling Trees (Machine abatteuse-billonneuse électrique pour le sciage et l'abatage des bois). Revue Générale de l'Electricité, vol. 4, no. 21, Nov. 23, 1918, pp. 165D-166D, 2 figs. An abstract is given of French patent no. 469,995, describing electrically-driven circular saw for felling trees.

MATERIALS OF CONSTRUCTION AND TESTING OF MATERIALS

Cast Iron

Wearing and Anti-Frictional Qualities of Cast Iron, J. E. Hurst. Iron & Coal Trades Rev., vol. 97, no. 2647, Nov. 15, 1918, pp. 546. Abstract of "Preliminary Note" to a Carnegie Scholarship Memoir.

Porcelain

Some Types of Porcelain, F. H. Riddle and W. W. McDanel. Jl. Am. Ceramic Soc., vol. 1, no. 9, Sept. 1918, pp. 606-627, 13 figs. Determination of burning range of porcelain bodies having covering fired at cone 10 and above. Composition of bodies used varied from 45 to 85 per cent clay content and from 10 to 30 per cent flux.

See also METALLURGY, *Iron and Steel (Tests)*; CIVIL ENGINEERING, *Cement and Concrete*.

MEASUREMENTS AND MEASURING APPARATUS

Boiler Feedwater

Measuring Boiler Feedwater, D. L. Fagnan. Nat Engr., vol. 23, no. 1, Jan. 1919, pp. 18-22, 5 figs. Discussion of various methods; principles of operation and construction of representative types. Paper before Nat. Assn. Stationary Engrs.

Calorimeters

The Calorimetry of Coal. Engineering, vol. 107, no. 2767, Jan. 10, 1919, pp. 33-36, 10 figs. A description of the calorimeter and its use.

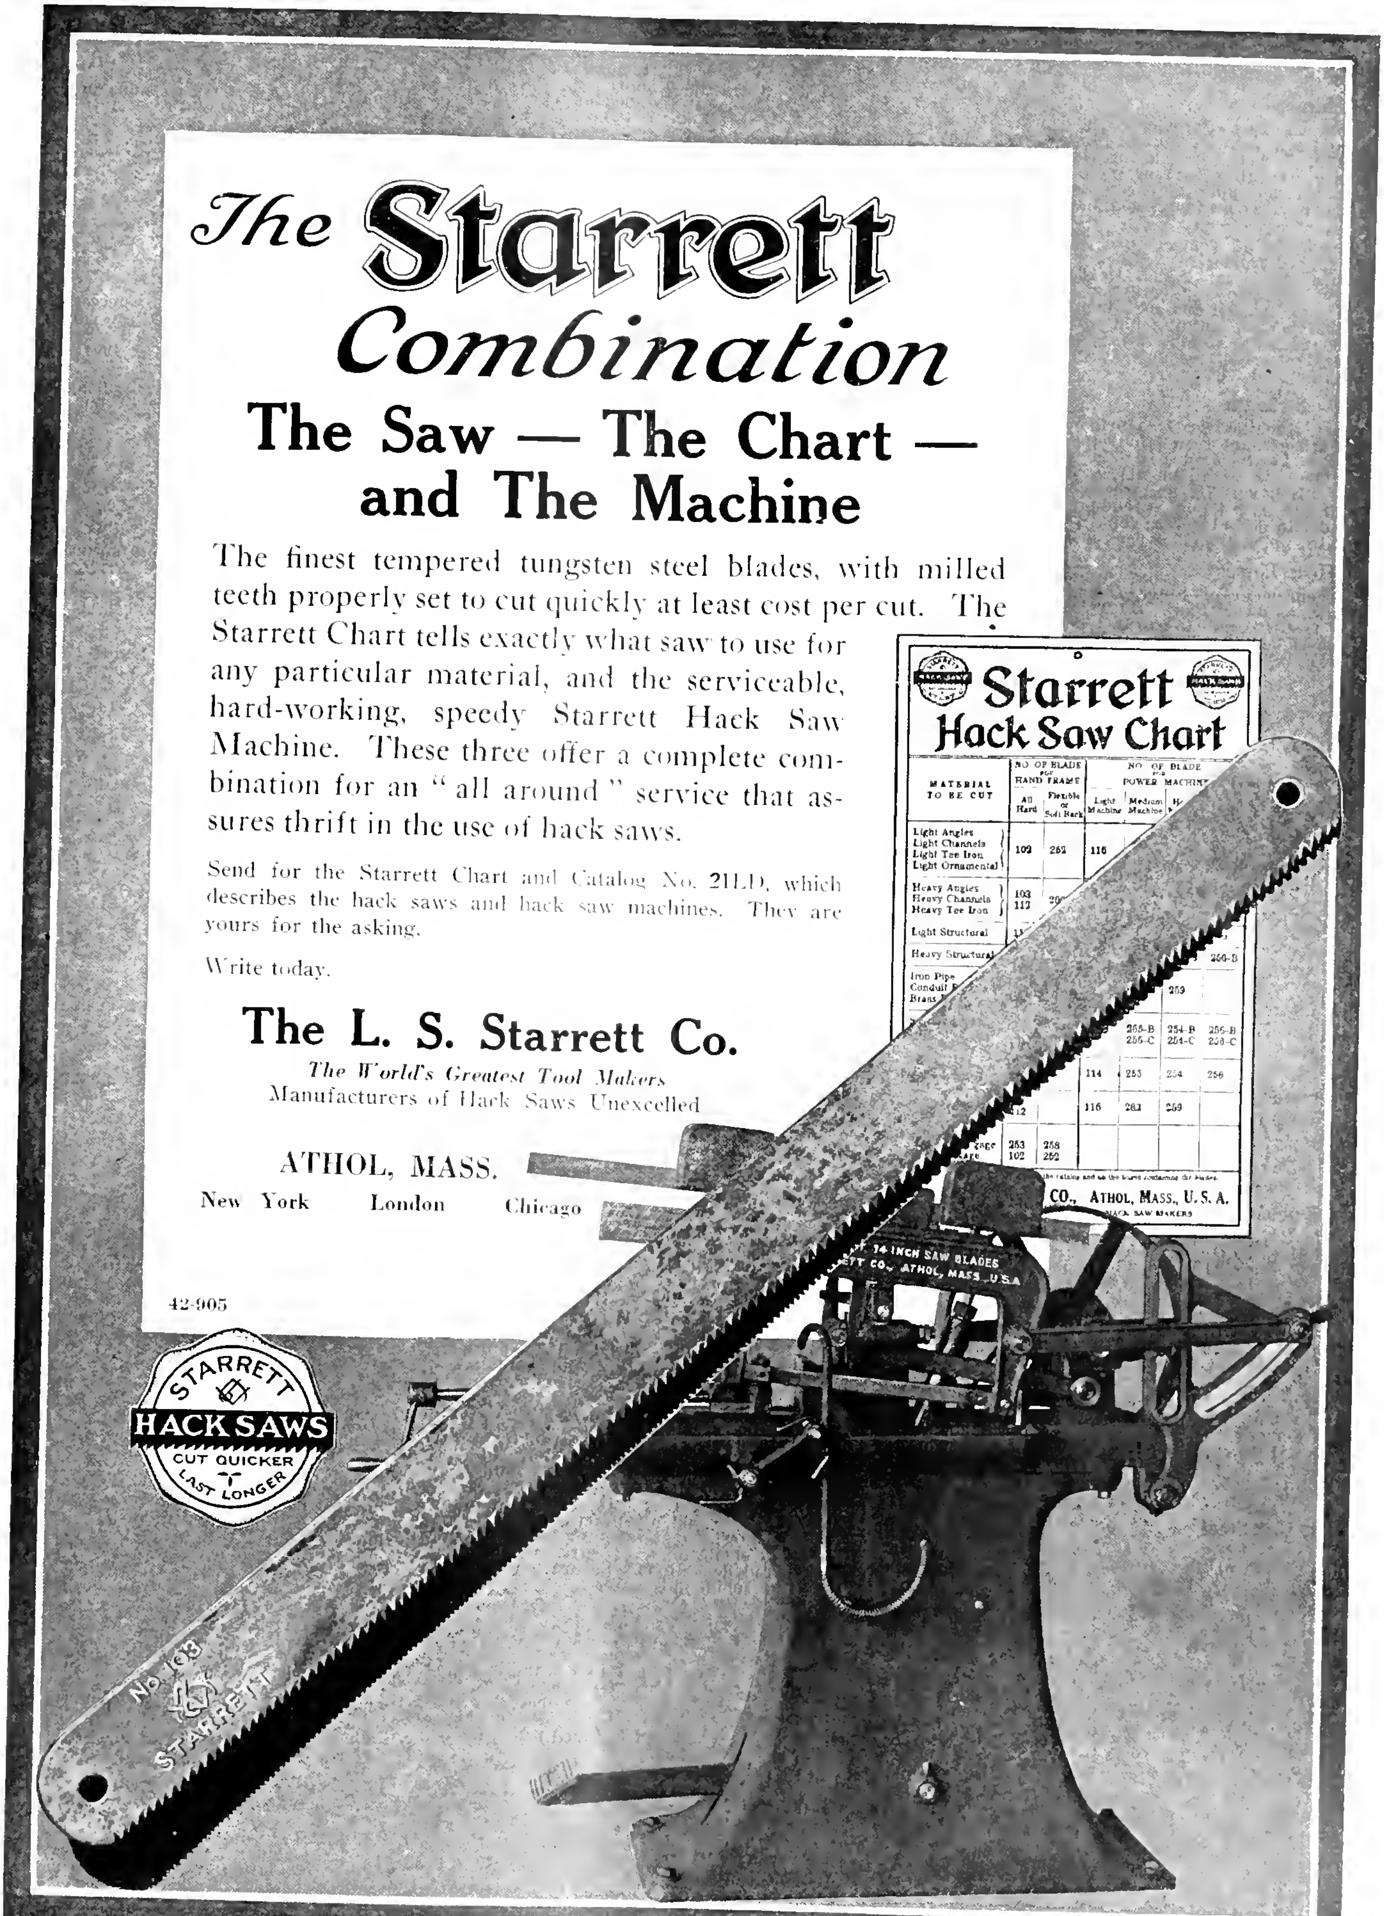
Compressibility of Solids

The Determination of the Compressibility of Solids at High Pressures, Leason H. Adams, Erskine D. Williamson and John Johnston. Jl. Am. Chem. Soc., vol. 41, no. 1, Jan. 1919, pp. 12-42, 12 figs. Essence of method is to compare change of volume under hydrostatic pressure of a cylinder of a material and that of a similar soft-steel cylinder the compressibility of which is assumed as $0.60/10^6$ cm.^{2} per megadyne at all pressures. Results are presented for 16 materials (metals, alloys and salts) at pressures up to 12,000 megabars.

Hardness

Hardness of Soft Iron and Copper Compared, F. C. Kelley. Iron & Steel Can., vol. 1, no. 11, Dec. 1918, pp. 433-434. Tests by Brinell methods on samples of American ingot iron and ordinary commercial cold-rolled copper which were given similar treatments in an electrically heated vacuum furnace.

Instruments for Hardness Tests, C. E. Clewell. Am. Mach., vol. 50, no. 3, Jan. 16, 1919, pp. 93-96, 5 figs. Importance of hardness tests; early forms of Brinell hardness determination and recent modifications; use of scleroscope as check on pyrometer; methods suggested for holding materials under test.



The Starrett Combination
The Saw — The Chart — and The Machine
The finest tempered tungsten steel blades, with milled teeth properly set to cut quickly at least cost per cut. The Starrett Chart tells exactly what saw to use for any particular material, and the serviceable, hard-working, speedy Starrett Hack Saw Machine. These three offer a complete combination for an "all around" service that assures thrift in the use of hack saws.
Send for the Starrett Chart and Catalog No. 21LD, which describes the hack saws and hack saw machines. They are yours for the asking.
Write today.

STARRETT HACK SAWS CUT QUICKER LAST LONGER
No. 103 STARRETT

Testing Materials for Hardness, Howard Ensaw. Am. Mach., vol. 50, no. 6, Feb. 6, 1919, pp. 257-258. Describing some methods of testing materials for hardness.

Pyrometers

How to Test Pyrometer Efficiency. Iron Trade Rev., vol. 64, no. 2, Jan. 9, 1919, pp. 158-159, 5 figs. Method provides for maintenance of calibrated platinum-platinum-rhodium thermocouple and comparison of this standard with the instruments that are to be tested.

Standards of Temperature and Means for Checking Pyrometers. Proc. Steel Treating Research Soc., vol. 2, no. 1, 1919, pp. 30-37, 7 figs. Method for carrying out necessary tests and suggestions of various equipments suitable for determining inaccuracies in pyrometer readings, which, it is said, are always traceable to thermocouple, measuring instruments or lead wires.

Shearing Strength

New Machine for Measuring the Shearing Strength of Cast Iron (Nouvelle machine pour mesurer la résistance de la fonte par la méthode du cisaillement). Ch. Fremont. Génie Civil, vol. 73, no. 26, Dec. 28, 1918, p. 516, 9 figs. Also Comptes rendus des séances de l'Academie des Sciences, vol. 167, no. 24, Dec. 9, 1918, pp. 949-952, 9 figs.

Stack Heat Losses

Measurement of Stack Heat Losses, J. H. Blakey. Power Plant Eng., vol. 23, no. 3, Feb. 1, 1919, pp. 151-152, 2 figs. Electrical device embodying simplicity and accuracy for determining stack heat losses.

See also ELECTRICAL ENGINEERING, *Measurements and Tests (Thermocouples and Pyrometers)*

MECHANICAL PROCESSES

Barrels, Steel

Manufacture of Steel Barrels, Edward K. Hammond. Machy., vol. 25, no. 6, February, 1919, pp. 526-533, 19 figs. Blanking the barrel heads, bending the sheets for the bodies, welding flanging, brazing, bilging, pickling and testing.

Boiler Manufacture

How to Design and Lay Out a Boiler—III. William C. Strott. Boiler Maker, vol. 19, no. 1, Jan. 1919, pp. 10-12, 4 figs. Thickness of butt straps; rivet failures due to tearing of plate, stretching of holes or tendency to shear. (To be continued.)

Boiler Smoke Tubes

The Repair of Steel Boiler Smoke-Tubes. Ry. Gaz., vol. 29, no. 26, Dec. 27, 1918, pp. 729-731, 4 figs. Specifications to which tubes are purchased; operations in repairing of tubes removed from boiler.

Brass Extrusion

The Extrusion of Brass, Alfred Hutt. The Central (Jl. City & Guilds Eng. Col.), vol. 15, no. 44, Dec. 1918, pp. 68-77, 5 figs. Description of a brass extrusion press. By extrusion is meant process whereby a plastic substance is given a definite shape by being forced through an orifice or die under pressure. Alloy used is Muntz metal consisting of 60 per cent copper and 40 per cent zinc.

Cement Mills

Operating Details of an Electrically Operated Cement Mill. Elec. Rev., vol. 74, no. 6, Feb. 8, 1919, pp. 210-212, 4 figs. Progress of material through mill; process of cement manufacture; apparatus and size of motor utilized.

Chains, Cast-Steel

The Manufacture and Testing of Cast Steel Chain Cables. Jl. Am. Soc. Naval Engrs., vol. 30, no. 4, Nov. 1918, pp. 858-862. Memorandum issued by Lloyd's Register of Shipping. From Engineer.

Coke Manufacture

Plant of the Seaboard By-Product Coke Company, D. Mac Arthur. Gas Age, vol. 43, no. 2, Jan. 15, 1919, pp. 69-73, 9 figs. Coke-loading equipment; electrical control switchboard; light-oil extraction and refining. (Concluded.)

Cotton Compression

Economics of High Density Cotton Compression, Richard Hoadley Tingley. Textile World Jl., vol. 55, no. 2, Jan. 11, 1919, pp. 133, 191 and 381, 4 figs. Description of present compression methods; brief history of high-density movement.

Dies

Making Dies for Cutting Rubber, Leather, Paper, Cloth, etc., S. A. Hand. Am. Mach., vol. 50, no. 2, Jan. 9, 1919, pp. 52-54, 11 figs.

Kilns

The Use of Car Tunnel Kilns for Brick and Other Products of Crude Clays, Ellis Lovejoy. Jl. Am. Ceramic Soc., vol. 1, no. 9, Sept. 1918, pp. 628-634, and (discussion) pp. 634-636. Features and respective values of (1) direct heating in car-tunnel kilns, (2) indirect heating in tunnel, and (3) compartment-operation types of car-tunnel kilns.

Lubricator, Mechanical

Manufacturing a Mechanical Lubricator, M. E. Hoag. Am. Mach., vol. 50, no. 2, Jan. 9, 1919, pp. 71-74, 13 figs. (Third article.)

Machine Knives

Making Machines Knives, W. F. Sutherland. Can. Machy., vol. 21, no. 4, Jan. 23, 1919, pp. 73-77, 8 figs. Operations connected with welding and grinding of knives for wood-working tools and paper cutters.

Magnetos

The Magneto Industry. Engineer, vol. 127, no. 3289, Jan. 10, 1919, pp. 26-29, 12 figs. Description of the Thomson-Bennett Works, Birmingham.

Plate Mills

New Plate Mills with Modern Lay-Out. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 43-47, 8 figs. Designed to give sufficient capacity of heating, finishing and shipping.

Lukens New Plate Mill Largest in the World. Boiler Maker, vol. 19, no. 1, Jan. 1919, pp. 6-10, 6 figs. Mill is of 4-high type with rolls 204 in. wide, and will roll 5000 tons of plate per week.

Pliers

The Liberty Plier; Drop-Forged Victory. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 32-35. Distribution of work and sanitary dispositions at Krauter plant where 23,000,000 forgings have been completed during last 18 months.

Sugar Manufacture

Sugar Factory Engineering, C. B. Thompson and J. O. Frazier. Nat. Engr., vol. 23, no. 1, Jan. 1919, pp. 23-26, 2 figs. Problems peculiar to industry and equipment details of factory; preparation and burning of bagasse; arrangement of multiple effect.

Tin Plate

Tin Plate Manufacturing and Detinning. Engineering, vol. 106, no. 2764, Dec. 20, 1918, pp. 701-702. An historical article.

See also ELECTRICAL ENGINEERING, *Power Applications (Steel-Mill Drives)*

MECHANICS

Shafts, Whirling Speed of

The Whirling Speed of Shafts Supported in Three Bearings, Arthur Morley. Engineering, vol. 106, no. 2760, Nov. 22, 1918, pp. 573-574, 3 figs. Introduction notation; calculation from equation of energy; method of successive approximation; application of various forms of support; Dunkerley's empirical rule; Bauman's method. (To be continued.)

New Critical Shaft Speeds as Effects of the Gyroscopic Disc-Action, A. Stodola. Engineering, vol. 106, no. 2763, Dec. 13, 1918, pp. 665-666, 4 figs. Mathematical development.

Springs

A New Theory of Plate Springs, David Landau and Percy H. Parr. Jl. Franklin Inst., vol. 187, no. 1, Jan. 1919, pp. 65-97, 14 figs. Study of trapezoidal, circular, parabolic and square leaf points. It is concluded that tapering points of leaves of leaf springs in plane of width only has no practical effect on strengths, reactions, stresses, or flexibilities of springs. Calculations of stresses, bending moments and deflections. Separation of loads in the top compound plate.

A Theory of Plate Springs, David Landau and Percy H. Parr. Jl. Soc. Automotive Engrs., vol. 4, no. 2, Feb. 1919, pp. 67-72, 9 figs. Based on assumption that any leaf of a spring can be considered as a beam, encastré at one end, loaded at the other, and having a flexible support somewhere between the point of encastrement and that of application of the load. (To be continued.) From Jl. Franklin Inst.

Wires, Tension in

Rapid Determination of the Tension in Stretched Electric Wires (Récherche rapide de la tension à laquelle travaille le metal dans les canalisations électriques sous l'action de l'effort de traction), Jean Hely. Revue Générale de l'Electricité, vol. 5, no. 1, Jan. 4, 1919, pp. 26-27, 1 fig. Chart constructed on physical law of vibration of chords. Tension determined from number of transversal vibration of a known length.

MOTOR-CAR ENGINEERING

Air Cleaners

Carbureter Air Cleaners, W. G. Clark. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 18-22 and (discussion) pp. 22-23, 14 figs. Classification and description of four types: cleaners having cloths or screens or both, inertia cleaners, those in which water or some other liquid is used to wash air, and centrifugal or gravity cleaners.

Design

1919 Engineering Trends, H. Ludlow Clayden. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 88-89, 94-97 and 157, 11 figs. Graphs showing increase of crankshaft revolutions per mile, increase in stroke-bore ratio, tendencies in drive of accessories, comparative percentages of disk and cone clutches, use of vacuum gasoline feed, use of spiral bevel drive and changes in lubricating systems.

Trucks Show Few Mechanical Changes. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 110-111, 4 figs. Claims that war activities have retarded mechanical development in commercial vehicle design and that curtailment of supplies of raw material has reduced production originally planned.

Automotive Industry Achievements in 1918. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 44-48, 2 figs. Development in tractor, truck, trailer and aeroplane manufacture; relation of drop-forging industry to automotive-engine evolution.

Fuels

Benzol as a Motor Fuel, S. E. Whitehead. Gas Jl., vol. 144, no. 2901, Dec. 17, 1918, pp. 615-616. Remarks that a Motor Union Committee in 1907 reported they had successfully used benzol, either alone or in combination with petrol, as motor fuel. It then takes up more in detail properties of benzol and its intrinsic adaptability as motor fuel.

The Motor Fuel Problem, W. R. Ormandy. Petroleum Rev., vol. 39, nos. 853, 854 and 855, Nov. 23 and 30, Dec. 7, 1918, pp. 335-336, 355-356 and 363. Demand and supply of motor fuels in British Empire. Solid gaseous and liquid fuels are considered separately.

Headlights

The Requirements of Automobile Headlights. Illum. Engr., vol. 11, no. 9, Sept. 1918, pp. 209-211. Report of a committee on the Illum. Eng. Soc.

Horns

Electrical and Mechanical Warning Signals for Automobiles, Fred I. Hofman. Automotive Industries, vol. 40, no. 2, Jan. 9, 1919, pp. 47-50, 21 figs. Principles involved in operation of diaphragm signals; relative advantages of electric motor horn, electric vibrator horn and hand-operated horn; variety in mechanism of hand horns.

Kerosene Engines

Bellem-Brégéras Method of Using Refined Petroleum and Heavy Oils in Low-Compression Oil Engines (Emploi du pétrole lampant et des huiles lourdes dans les moteurs à explosion à basse compression. Procédés Bellem et Brégéras. Génie Civil, vol. 73, no. 22, Nov. 30, 1918, pp. 433-435, 3 figs. Description of machine which obtained 50,000-franc prize offered by the Chambre Syndicate des Industries du Pétrole for best automobile petroleum engine. Account of tests also given.

Locking Devices

Automobile Locking Devices. Jl. Soc. Automotive Engrs., vol. 4, no. 2, Feb. 1919, pp. 97-98, 1 fig. Results of study of automobile locking devices by committee of Soc. Automobile Engrs.

Lubrication

Lubrication and Fuel Tests on Buda Tractor Type Engine, P. J. Dasey. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 50-53, 5 figs. Horsepower developed at different speeds by four fuels; power developed per lb. of fuel, fuel consumption in lb. per b-hp. hr.

Production

Future Production Plans Will Require Special Machinery, J. Edward Schipper. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 145-149, 13 figs. Description of certain machines which permit production on large scale and forecast of developments on jigs, tools, gases, etc., necessary to fit into efficient production scheme.

Spark Plugs

Effect of Temperature on Spark Plug Insulations. Automotive Industries, vol. 40, no. 1, Jan. 2, 1919, p. 25, 1 fig. Experiments carried out in England show that minimum permissible insulation resistance varies with frequency of sparks and compression pressure.

Statistics

Truck Production for 1918 Is 250,000. Automotive Industries, vol. 40, no. 3, Jan. 16,

HUNT MACHINERY

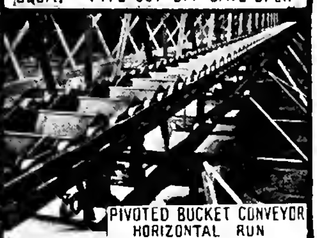
"SQUAT" TYPE CUT OFF GATE-OPEN



PIVOTED BUCKET CONVEYOR HORIZONTAL RUN

47 YEARS AGO

In 1872 the Automatic Railway, the first real improvement over the time-worn "Hand" method of handling coal, was invented by Charles W. Hunt.

Since that time the Company he founded, and which bears his name, has developed many other **UNIQUE LABOR SAVING AND LABOR AIDING DEVICES** for storing and transferring coal, ashes, ore, sand, gravel, fertilizer and other bulk materials, as well as manufactured packaged products.

The list above indicates the scope of the Hunt Line, and our Engineers will be glad to confer with those interested in this subject—

SAVING IN HANDLING MATERIAL

1919, pp. 128-129, 1 fig. Gain of 32 per cent over 1917. Proportion of trucks of each regular capacity shown diagramatically.

Tanks

U. S. A. Two-Man Tank Fitted with Motor Car Engines. Motor Age, vol. 35, no. 2, Jan. 9, 1919, pp. 16-18, 6 figs. Automotive Industries, vol. 40, no. 2, Jan. 9, 1919, pp. 43-46, 6 figs. Motor Age: Adaptation of standard units in construction of Ford tank. Automotive Industries: Two-man fighting machine having a duplicate Ford automobile power plant, radiator mounted at rear, worm drive.

U. S. Tank and Tractor Details. Motor Age, vol. 34, no. 26, Dec. 26, 1918, pp 20-21, 4 figs. Cargo carrier Mark VII; Ford tank.

Tractors, Specifications for

Detailed Technical Specifications of Gasoline Farm Tractors for 1919. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 176-179. Tabulated data on 98 different makes of American types produced by 69 manufacturers with makes of principal parts, including engine, governor, lubricator, ignition system, air cleaner, gear set, clutch and axle.

Trucks, Specifications for

Detailed Technical Specifications of Gasoline Motor Trucks for 1919. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 112-127. Full particulars on types and makes of principal truck parts, including engines, clutches, gear sets, rear axles, steering gears, governors and electric and fuel sytems; 489 gasoline, 19 electric and one steam motor-truck chassis described.

Water Injection

Mixing Water with Gasoline. Motor Boating, vol. 23, no. 1, Jan. 1919, 25-26, 9 figs. Advantages gained by introducing limited quantities of water into intake manifold. Its use as a decarbonizing medium.

POWER GENERATION

Appalachians

New Plant of the Appalachian Power Company, H S. Slocum Elec. World, vol. 73, no. 3, Jan. 18, 1919, pp. 123-127, 9 figs. Steam station rated at 20,000 kw. just completed to supplement hydroelectric plants in meeting heavy industrial demands; development of rich mining district due largely to central station power supply.

Canada

Electric Power Generation in Ontario on Systems of Hydroelectric Power Commission, Arthur H. Hull. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 1, Jan. 1919, pp. 29-52, 16 figs. Systems of Hyroelectric Power Commission of Ontario.

Canada Builds 300,000 Hp. Niagara Hydro Plant, Louis R Black. Mine & Quarry, vol. 11, no. 1, Nov. 1918, pp. 1097-1101, 8 figs. Hydro Electric Power Commission of Ontario is engaged upon construction of a canal $8\frac{1}{2}$ miles long, which will divert a flow of 10,000 sec.-ft. of water from Niagara Falls and enable 300,000 hp. to be developed.

Centralization

Central Station Power for Mines, A. Tancig. Bul. Affiliated Eng. Societies Minn., vol. 3, no. 12, Dec. 1918, pp. 205-207. Advantages to each mine of centralized power generation.

Transportation and Power, C. G. Gilbert and J. E. Pogue. Can. Engr., vol. 36, no. 2, Jan. 9, 1919, pp. 128-130. Advantages and disadvantages of centralization of power stations and generation of electrical energy in bulk. Excerpt from report to Smithsonian Instn. on Power: Its Significance and Needs.

Centralizing Power Production. Power Plant Eng., vol. 23, no. 2. Jan. 15, 1919, pp. 99-104, 9 figs. Operation of dual driven auxiliaries, induced draft and modern coal and ash handling equipment features of Cromby Station of Philadelphia Suburban Gas & Electric Co.

Eastern States

Development of Hydroelectric Resources in Eastern United States, D. H. Colcord. Elec. Rev., vol. 74, no. 6, Feb. 8, 1919, pp. 207-209, 4 figs. Deterring influences and development outlined; brief review of what has been accomplished; urgent needs and benefits of hydroelectric developments.

Glaciers

Power from Glaciers. Electric Traction, vol. 15, no. 1, Jan. 15, 1919, pp. 1-4, 9 figs. Addition to White River Power Plants of Puget Sound Traction Light & Power Co. for electrification of Milwaukee Ry.

Hetch Hetchy

The Power Project at Hetch Hetchy, Rudolph W. Van Norden. Jl. Elec., vol. 42, no. 2, Jan. 15, 1919, pp. 65-66, 2 figs. Gives details of 66,000-hp. development at Moccasin Creek, a part of project planned by city of San Francisco.

Maine

Investigation of Maine Water Powers. Elec. World, vol. 73, no. 3, Jan. 18, 1919, pp. 120-121, 1 map. Public Utilities Commission sends to governor and council results of an exhaustive study of water-power resources; hydroelectric systems, power sites, plant locations and storage conditions dwelt on.

Massachusetts

Development of Massachusetts' Water Power. Elec. World, vol. 73, no. 6, Feb. 8, 1919, pp. 272-273, 1 map. From the report of a special commission to investigate the facilities and possibilities in this direction; Action urged; public ownership declared to be of doubtful value as a water-power policy.

Michigan

Simplicity Marks Michigan's Largest Hydroelectric Development. Elec. Rev., vol. 74, no. 5, Feb. 1, 1919, pp. 167-170, 6 figs. Simplicity of layout, coordination of turbines installed to water flow and 140,000 volt transmission line are features of the Junction Development.

Pacific Coast

Water-Power Development on the Pacific Coast, George F. Sever. Elec. World, vol. 73, no. 4, Jan. 25, 1919, pp. 177-178; Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 6-10. Elec. World: Study of economic and financial conditions leads to outline of developments approximating $50,000,000 cost, all power furnished can be absorbed easily within two years after development. Jl. Elec.: Survey of projects in progress of construction in California, rules of Forest Service in their relation to hydroelectric development. From paper before San Francisco Association of Members of Am. Soc. C.E.

Tennessee

The Larger Undeveloped Water-Powers of Tennessee, J. A. Switzer. Gen. Meeting Am. Electrochem. Soc., Apr. 30, 1918, paper 24, pp. 169-202, 15 figs. Power sites and essential data pertaining to their development and exploitation.

Tides

Utilization of Power from Tides (Etude sur l'utilisation des marées pour la production de la force motrice), E. Maynard Revue Générale de l'Electricité, vol. 4 nos. 22, 23, 24, 25 and 26, Nov. 30, Dec. 7, 14, 21 and 28, 1918, pp. 823-843, 865-877, 903-914, 917-959 and 997-1007, 34 figs. Nov. 30: Derivation of continuous power from tide basins and sea reaches; application of system to St. Malo and La Rochelle regions. Dec. 7: Continuous power of operation at set intervals after high and low tides; application to St Malo and La Rochelle. Dec. 14: System comprising two basins to utilize ebb and flow currents respectively so as to produce continuous work; application of plan to St. Malo and La Rochelle. Dec. 21: Application of processes described in previous articles to Rotheneuf Bay, near St. Malo (Ille-et-Vilaine), and Bay of La Rochelle. Dec. 28: Possibilities at mouth of La Rance river in 21-km., region where action of tides is felt.

POWER PLANTS

Boiler Corrosion

Action of Water on Metals, S. W. Parr. Can. Engr., vol. 36, no. 3, Jan. 16, 1919, p. 148. Reactions involved when alkaline waters are used in steam generators. Paper before Ill. Section, Am. Water Works Assn.

Boiler Operation

Safety and Economy in the Boiler Room, W. E. Snyder. Iron Age, vol. 103, no. 5, Jan. 30, 1919, pp. 306-307. Practical suggestions for reducing hazards and increasing efficiency; thorough inspection and careful training of men required. From a paper before the Engineers' Society of Western Pennsylvania.

The Chemical and Physical Control of Boiler Operation, E. A. Uehling. Mech. Eng., vol. 41, no. 2, Feb. 1919, pp. 137-141 and 199, 1 fig. Formulæ for calculating heat losses in chimney gases and their application to data derived from autographic records of CO_2.

Boiler Settings

Combustion and Boiler Settings, A. D. Williams. Power, vol. 49, nos. 2 and 6, Jan. 14 and Feb. 11, 1919, pp. 57-59 and 205-208, 2 figs. Jan. 14: Notes on location of heating surfaces, placing of baffles, and formation of soot in relation to combustion. Feb. 11: Effect produced on combustion reactions and circulation of gases by the chilling due to contact with water-cooled surfaces.

Drip Water

Saving and Returning Drip Water, William E. Dixon. Power Plant Eng., vol. 23, no. 2, Jan. 15, 1919, pp. 105-109, 9 figs. Where drip taps should be made; methods employed for returning condensate; utilizing oily drips.

Economizers

Care of Economizers, J. F. Daggett. Power, vol. 49, no. 6, Feb. 11, 1919, pp. 192-193, 4 figs. Some suggestions as to the operation and care of economizers.

Equipment

Power Station at Mark Plant, Gordon Fox. Power Plant Eng., vol. 23, no. 3, Feb. 1, 1919, pp. 141-144, 4 figs. Describes power plant of the Sheet Tube Company of America, dealing with turbine generators and blower, condensing system and electric features. Second article.

Exhaust Steam

Utilizing Exhaust Steam in Knitting Mill, L. H. Stark. Nat. Engr., vol. 23, no. 1, Jan. 1919, pp. 2-6, 5 figs. How savings were effected by several changes in equipment and use of indicating and recording devices.

Firebox

Boiler Efficiency Increased by New Type of Firebox. Ry. Age, vol. 66, no. 2, Jan. 10, 1919, pp. 151-153, 2 figs. Eighteen per cent greater evaporation per pound of coal secured in tests on C., M. & St. P.

Hand-Fired Plants

Fuel Economy in Hand-Fired Power Plants. Power Plant Eng., vol. 23, no. 2, Jan. 15, 1919, pp. 110-113, 4 figs. Fifth installment of abstract of Circular No. 7, Univ. of Ill., Eng. Experiment Station.

Low-Grade Fuels

Peace Problems in the Power Plant, George H. Perkins and Perry Barker. Textile World Jl., vol. 55, no. 2, Jan. 11, 1919, pp. 391-392. Importance of continuing war economies; difficulties in use of low-grade fuels.

Operation

Turbine House Plant Operation, T. G. Otley and V. Pickles. Elecn., vol. 82, no. 2120, Jan. 3, 1919, pp. 4-6. Abstract of a paper read before the South African Institute of Electrical Engineers.

Stokers

Power Plant Management—VII. Mechanical Stokers, Robert June. Refrig. World, vol. 54, no. 1, Jan. 1919, pp. 25-26, 2 figs. Adaptability of various types of stokers according to ratings of boilers; points to remember regarding stoker operation.

Automatic Cleaning Under-Feed Stoker Nat. Engr., vol. 23, no. 1, Jan. 1919, pp. 100-102, 4 figs. Type developed by Under Feed Stoker Co. is similar to standard Jones stoker but is self-cleaning.

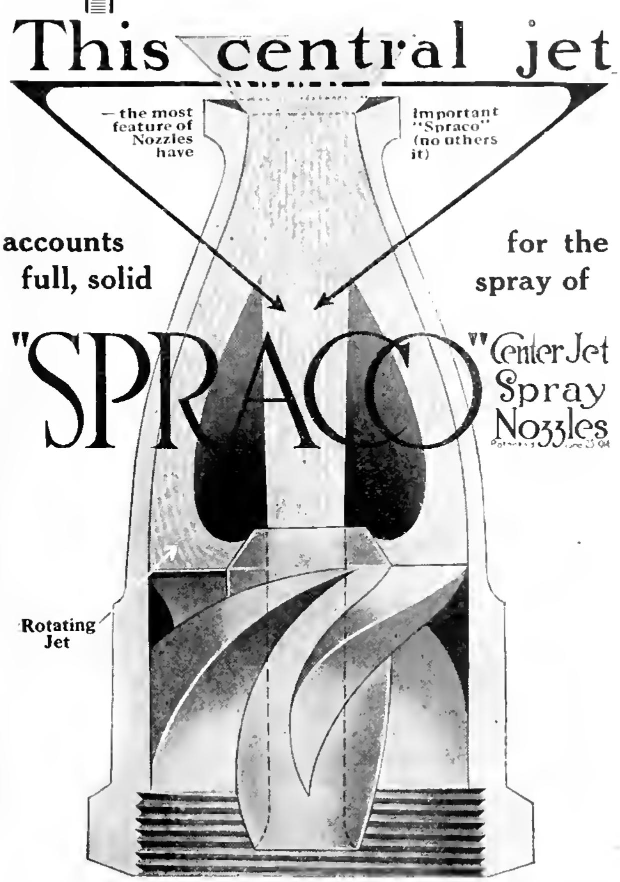
SPRACO

Spraco Cooling System



The war is won, but the necessity for conservation is as great as ever. The whole world needs coal—we must save every pound possible. Spraco Equipment, which helped to put many plants on a basis of wartime efficiency, is ready for the work of reconstruction.

The Spraco Cooling System (with Spraco Center Jet Nozzle) saves fuel and cuts operating costs. Under ordinary conditions it will cool condensing water sufficiently to insure an average vacuum of 27 inches or better, throughout the year. And compared to a cooling tower the Spraco System costs much less to install, about one-half as much to operate and practically nothing to maintain.

Our engineers are at your service—ready to submit drawings, specifications and estimates covering an installation in your plant. A word from you will bring full details.

SPRAY ENGINEERING CO.

93 Federal St., - Boston, Mass.

Engineers *Manufacturers*

SEE OUR DATA IN 1918 A.S.M.E. CONDENSED CATALOGUES OF MECHANICAL EQUIPMENT

PRODUCER GAS

German Producers

New Coke-Fired German Gas Producer. Iron Age, vol. 103, no. 3, Jan. 16, 1919, pp. 180-181, 1 fig. Makes gas low in moisture and sulphur; pig iron high in manganese and phosphorus a by-product.

Producer-Gas Users

Modern Applications of Producer Gas, Earl E. Adams. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 41-44, 2 figs. Its use in heat-treating and carbonizing furnaces; economy and general advantages.

Wuerth Producer

The Wuerth Gas Producer. Foundry Trade Jl., vol. 20, no. 203, Nov. 1918, pp. 600-601, 1 fig. Features of apparatus which is worked on blast-furnace principle and consists of a hearth without grating, a bosh and a shaft. From Stahl und Eisen.

PUMPS

Centrifugal Pumps

High-Lift Centrifugal Pumps for Irrigation, B. P. Fleming. Power, vol. 49, no. 4, Jan. 28, 1919, pp. 133-136, 3 figs. Water forced through steel manifold to reinforced-concrete conduit leading up to canal; design features; pump tests show over 81 per cent efficiency under 90-ft. head.

Pump Station

A Non-Drowning Pump-Station, C. Erb Wuench. Min. & Sci. Press, vol. 118, no. 1, Jan. 4, 1919, p. 18, 1 fig. Design utilizing principle of hydraulic diving bell.

Vacuum Pumps

Automatic Variation of Gas Pressure and Its Application to a Vacuum Pump, Circulation of Gases, Magnetic Stirrer, O. Maas. Jl. Am. Chem. Soc., vol. 41, no. 1, Jan. 1919, pp. 53-59, 3 figs. Control apparatus by means of which pressure established by a Geissler, or any other suction pump, can be automatically varied between definite limits and the period of each variation can be adjusted to any desired length of time.

REFRACTORIES

Corrosion

Report on the "Corrosion Action of Flue Dust on Fire-Bricks," J. W. Mellor. Gas. Jl., vol. 144, no. 2897, Nov. 19, 1918, pp. 421-423. Experimental research by refractory materials committee of Instn. Gas Engrs.

Crushing Resistance

Crushing Resistances of Refractory Materials (Mesure des résistances à l'écrasement des matériaux réfractaires), A. Bigot. Chimie & Industrie, vol. 1, no. 7, Dec. 1, 1918, pp. 724-726, 7 figs. Gives results of experiments on 1-in. cubes of silica brick, refractory argil, white bauxite, carborundum, etc., in charts.

Production

Our Present Knowledge Concerning the Industry of Refractory Products (Nos connaissances actuelles sur l'industrie des produits refractaires), J. Bied. Chimie & Industrie, vol. 1, no. 6, Nov. 1918, pp. 579-600, 23 figs. Invention of processes for utilizing dolomitic clinkers; calcination of magnesia from Eubée and Italy; manufacture of bricks; high-temperature resistance of silica-aluminum products.

Silica Products

Silica Products (Les produits de silica). Chimie & Industrie, vol. 1, no. 7, Dec 1, 1918, pp. 712-723, 7 figs. Chemical and physical analyses of siliceous rocks; photomicrographs of bricks manufactured in Martin furnaces.

South Wales

The Refractory Materials of South Wales, J. Allen Howe. Quarry, vol. 24, no. 263, Jan. 1919, pp. 11-15. Geological characters of carboniferous strata from which are obtained silica rocks, fireclays and dolomitic limestones. Paper before Refractories Section of Ceramic Soc.

Tests

Standard Tests for Refractory Materials. Quarry, vol. 24, no. 263, Jan. 1919, pp. 19-20. Chemical analysis of fireclays, dolomite and magnesite; identification of various forms of silica in silica bricks; physical tests. Report of Committee on Standardization of Tests for Refractory Materials, Refractories Section, Ceramic Soc.

Zirconia

Zirconia — Its Possibilities in Metallurgy, Leopold Bradford. Foundry Trade Jl., vol. 20, no. 203, Nov. 1918, pp. 596-597. History, occurrence, composition and uses; its application in refractory brick industry.

REFRIGERATION

Ammonia Compressors

The Ammonia Compression Refrigerating System—XXVI, W. S. Doan. Refrig. World, vol. 54, no. 1, Jan. 1919, pp. 33-34, 2 figs. Remarks on oil-cup scheme for external lubrication of open-type ammonia compressors.

Capacity and Power Consumption of Ammonia Compressors, Charles H. Herter. Refrig. World, vol. 54, no. 1, Jan. 1919, pp. 11-13, 1 fig. Graphs for the varying capacity and power consumption of compressors, at different pressures, compared to 20 lb. and 185 lb. as standard pressures.

Ammonia Condensers

Ammonia Condenser Data, Henry Torrance. Power, vol. 49, no. 3, Jan. 21, 1919, pp. 106-109, 6 figs. Author shows that both flooded atmospheric and flooded injector types of condensers are wrong in theory and practice. From July Jl. of Am. Soc. Refrig. Engrs.

Ammonia Recovery

Effects of Ammonia Recovery, T. B. Smith. Gas. Jl., vol. 144, no. 2902, Dec. 24, 1918, pp. 661-662. Comparison of the effects of the direct and the indirect processes upon the working of other parts of plant.

Export Business

The Trend of the Foreign Situation, L. W. Alwyn-Schmidt. Refrig. World, vol. 54, no. 1, Jan. 1919, pp. 21-22 and 32. Hints to refrigerating-machine manufacturers as to future of export business and necessity for immediate action.

Freezing Tanks

Care and Maintenance of Freezing Tanks, F. L. Brewer. Ice and Refrigeration, vol. 56, no. 1, Jan. 1919, pp. 41-42. How to lower cost of freezing tank; erecting and insulating tank; causes of leakage in sides and corners. Paper before Nat. Assn. Practical Refrig. Engrs.

History

The Growth and History of Refrigeration, James F. Patton. Power House, vol. 11, no. 12, Dec. 1918, pp. 351-353, 5 figs. Dependence of cities, battleships and armies in field on refrigerating plant.

Ice Plants

Building Ice Plant Efficiency, G. B. Bright. Ice & Refrig., vol. 56, no. 1, Jan. 1919, pp. 55-56. Tonnage and cost of manufacturing ice, 1904, 1908, 1918; changes necessary in steam plants to meet new conditions.

Large Converted Steam-Driven Ice Plant. Ice & Refrig., vol. 56, no. 1, Jan. 1919, pp. 63-65. Steam plant replaced by electric-power air-agitating system; cost.

Packing Industry

Refrigeration in the Packing House Industry. Refrig. World, vol. 54, no. 1, Jan. 1919, pp. 14-16, 5 figs. Recent improvement and additions to equipment made at plant of Armour Co., Hamilton, Can.

Meat Packing in South America. Refrig. World, vol. 54, no. 1, Jan. 1919, pp. 23-24 and 32. Data and comparisons of requirements and capacity of meat-packing and freezing plants of various companies in Argentina, Brazil, Paraguay, Uruguay and Columbia.

See also INDUSTRIAL TECHNOLOGY, Ammonia.

RESEARCH

Chemical Research

Address by Charles Frederick Juritz. South African Jl. Sci., vol. 15, no. 1, Aug. 1918, pp. 1-30. Exhortation to establish chemical research stations. Position of science in the present age; its use and abuse; its part in the war; industrial potentialities in advancement of chemistry. Presidential address before South African Assn. for Advancement of Sci.

Industrial Research

Science and Industry, J. C. Fields. Can. Engr., vol. 36, no. 2, Jan. 9, 1919, pp. 133-135. What Britain, United States, France and Japan are doing in industrial research. Results being obtained by manufacturers.

Switzerland

Organization for Public Welfare in Switzerland Based on Scientific Research at the Federal University. (Stiftung zur Foerderung Schweizerischer Volkswirtschaft durch Wissenschaftliche Forschung an der Eidgenoessischen Hochschule), Schweizerische Bauzeitung, Zurich, vol. 73, no. 1, Jan. 4, 1919, pp. 1-2. Swiss engineers are raising a fund of at least 500,000 francs with which to conduct researches of the Federal University with the object of assisting Switzerland to practice greater economy and efficiency in national life than in the past, and to help the country in overcoming the losses suffered during the war. The present article describes the organization and its constitution.

STANDARDS AND STANDARDIZATION

S. A. E. Standards

S. A. E. Standardization Work in 1918. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 158-171, 31 figs. Tables of new standards put on record, mainly relating to aeronautical, motorcycle and marine work.

Tires for Motor Cars

New Standard List of Pneumatic Tire Sizes. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 172-174, 21 figs. Collection of recently adopted S. A. E. standards and recommended practices relating to tires and rims.

STEAM ENGINEERING

Boilers

Espujols Inexplosible and Demountable Boiler (Générateur de vapeur inexplosible démontable, système d'Espujols. Génie Civil, vol. 73, no. 23, Dec. 7, 1918, p. 455, 2 figs. Inclination of tubes and other arrangements contribute to facilitate active circulation of water and steam, thus protecting boiler and increasing its efficiency.

Feeding and Circulating the Water in Steam Boilers, John Watson. Jl. Am. Soc. Naval Engrs., vol. 30, no. 4, Nov. 1918, pp. 834-838, 3 figs. Review of adaptation of various appliances. Abstract of paper before Inst. Marine Engineers. From Shipbuilding Shipping Rec.

The Waste Heat Boiler as Practical Steps in Fuel Conservation, H. D. Baylor. Concrete, Cement Mill Section, vol. 14, no. 1, Jan. 1919, pp. 5-6, 1 fig. Comparative data taken on two cement kilns 10 x 150 ft., dry process, using coal as fuel, before and after installation of waste-heat boilers. Paper presented before Portland Cement Assn.

Condensers

The Steam Condenser, Victor J. Azbe. Power Plant Eng., vol. 23, no. 3, Feb. 1, 1919, pp. 145-158, 4 figs. Gain by condensing, influencing conditions, cleaning tubes, cooling water systems.

Superheat

Determination of Superheating Surface, C. H. Baker. Power, vol. 49, no. 3, Jan. 21, 1919, pp. 86-89, 4 figs. Author gives charts showing relationship between superheat and factors that influence it.

Turbine Governors

Steam Turbine Governors, J. Humphreys. Iron & Coal Trades Rev., vol. 97, no. 2650, Dec. 13, 1918, pp. 661-662, 5 figs. Discussion of several types.

Turbines

2500-Hp. Rateau Marine Geared Turbines. Jl. Am. Soc. Naval Engrs., vol. 30, no. 4, Nov. 1918, pp. 842-849, 8 figs. Arrangement of 2500-shaft-hp. turbine set and double-reduction gearing at works of British Westinghouse Co. From Engineer.

A New Theory of the Steam Turbine, Harold Medway Martin. Mechanical Engineering, vol. 41, no. 2, Feb. 1919, pp. 150-154, 3 figs. Theory is based on assumption that steam is never in thermal equilibrium until condenser is attained. Abstract of serial in Engineering.

Steam Leakage in Dummies of the Lungstrom Type. Engineering, vol. 107, no. 2766, Jan. 3, 1919, pp. 1-3, 2 figs. Comparison of the results obtained by the use of a formula with step by step calculations of the discharge through a labyrinth using the precise formula given by Professor Callendar.

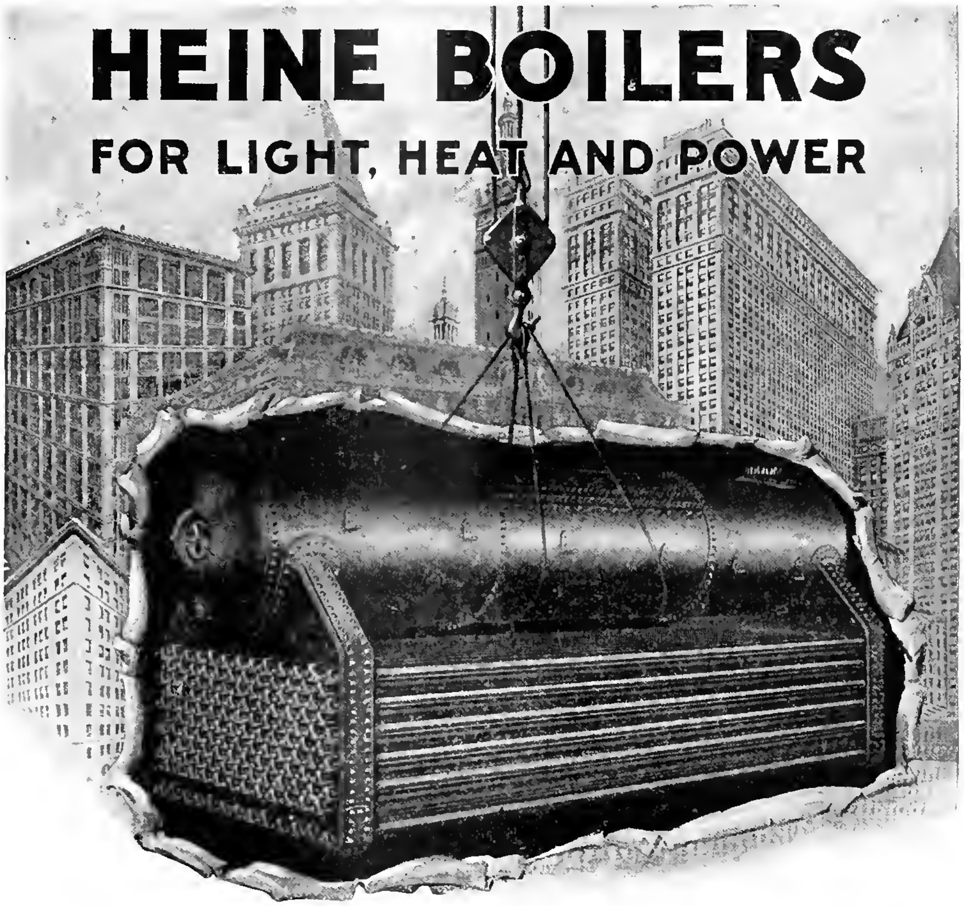
Steam Turbine Progress and Possibilities. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 495-497, 5 figs. Higher boiler pressures. Intermediate steam reheating in large multiple-cylinder machines. Feedwater heating. Economy to be expected from extended use of economizer.

Historical Development of the Steam Turbine—II. Power House, vol. 11, no. 12, Dec. 1918, pp. 346-349, 12 figs. Growth in size of turbo-generator units in recent years.

Operation of Steam Turbines, J. Humphreys. Iron & Coal Trades Rev., vol. 97, no. 2642. Oct. 18, 1918, pp. 430-432, 4 figs. Deals with Parsons turbine.

Land and Marine Steam Turbines. Engineering, vol. 106, no. 27ye, Dec. 13, 1918, pp. 674-675, 13 figs. Illustrations of details and brief description of steam turbines constructed by the Atlas Engineering Co., Copenhagen.

45,000 kw. Cross-Compound Steam Turbine. Elec. News, vol. 27, no. 24, Dec. 15, 1918, pp. 24-27, 4 figs. Unit consists of separate high- and low-pressure elements, each coupled directly to its own generator. High pressure



THEY ENJOY A GOOD REPUTATION

BECAUSE

Maximum heat is absorbed by combined radiation and absorption. Circulation is ideal.

There is nothing to get out of order. The Heine is virtually a "one-piece boiler."

Tubes are arranged for large heating surface per unit floor area.

Permanently installed soot cleaner.

For high overloads we place the lower baffle over the third row of tubes.

Write for your copy of "Boiler Logic."

HEINE SAFETY BOILER CO.

5321 Marcus Ave. ST. LOUIS, MO.

element is a single-flow, reaction type turbine running at 1800 r.p.m. and expanding to atmosphere; low-pressure element is a double-flow turbine of same type, running at 1200 r.p.m. and expanding to vacuum.

TEXTILES

Fabric Looms

An Apparent Revolution in Fabric Looms. Flight, Dec. 26, 1918, pp. 1463-1464, 4 figs. New Trautvetter loom claimed to weave (auto and aero fabric) diagonal threads in two directions as well as ordinary warp and weft.

THERMODYNAMICS

Heat Transmission

The Transmission of Heat Through Heavy Building Materials. Engineering, vol. 106, no. 2765, Dec. 27, 1918, pp. 735. From bulletin issued from University of London, University College, Department of Heating and Ventilating Engineering, entitled Report of Research on Transmission of Heat Through Heavy Building Materials, by Arthur H. Barker and M. Kinoshita.

WELDING

Arc Welding

Electric Arc Welding in Tank Construction, R. E. Wagner. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 899-911, 35 figs. Practice followed at Pittsfield works of General Electric Co.

A Review of Electric Arc Welding, John A. Seede. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 881-886, 11 figs. Evolution of present practice of arc welding.

Equipment Accessories Desirable in Electric Arc Welding. Elec. Ry. Jl., vol. 53, no. 2, Jan. 11, 1919, pp. 93-95, 6 figs. Proper protection of operator is essential and conveniences added insure better workmanship. From 1918 report of committee of Assn. of Ry. Elec. Engrs.

Notes on Regulations for Arc Welding. H. M. Sayers. Elecn., vol. 81, no. 2118, Dec. 20, 1918, pp. 715-717. Abstract of paper with discussion before the Institution of Electrical Engineers, Dec. 1918.

Arc-Welding Systems, Otis Allen Kenyon. Elec. Wld., vol. 73, no. 4, Jan. 25, 1919, pp. 167-171, 10 figs. Welding system discussed in a broad way, showing advantages and special usefulness of each method.

Cutting of Metals

The Cutting of Iron and Steel by Oxygen—XX, M. R. Amedeo. Acetylene & Welding Jl., vol. 15, no. 182, Nov. 1918, pp. 199-200. Cost of cutting. Translated by a member of the Union de la Soudure Autogene.

Inspection

Inspection of Metallic Electrode Arc Welds, O. S. Escholz. Am. Mach., vol. 50, no. 5, Jan. 30, 1919, pp. 215-217, 6 figs. Outlines the methods for satisfactory inspection tests.

Determining the Characteristics of Metallic-Electrode Arc Welds, O. S. Escholz. Elec. Ry. Jl., vol. 53, no. 6, Feb. 8, 1919, pp. 280-282, 3 figs. By testing and inspection of the welds a reliable indication of their soundness may be obtained.

Lead

The Autogenous Welding of Lead, V. P. Rosenberg. Acetylene & Welding Jl., vol. 15, no. 182, Nov. 1918, pp. 205-206, 2 figs. Power of blowpipe. (To be continued.)

Lloyd's Tests

Lloyd's Experiments on Electrically Welded Joints, H. Jasper Cox. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 864-870, 15 figs. Nature and description of experiments; summary of experimental results.

Oxy-Acetylene

The Oxy-Acetylene Flame and Blowpipe Efficiency, Arthur Stephenson. Acetylene & Welding Jl., vol. 15, no. 182, Nov. 1918, pp. 194-196, and (discussion) pp. 196-198, 5 figs. Diagram giving length of luminous cone in mm. for respective consumption of acetylene in litres per hour; graph showing diversity in acetylene consumption as specified by various makers for welding iron and steel; blowpipe movements. Paper before British Acetylene & Welding Assn. Also abstracted in Jl. Acetylene Welding, vol. 2, no. 7, Jan. 1919, pp. 338-344.

Rail Joints

New Type of Electrically Welded Joint Successful. Elec. Ry. Jl., vol. 53, no. 4, Jan. 25, 1919, pp. 182-183, 8 figs. Process used at St. Louis believed to eliminate cracking of rail around joint; applicable to new and old track.

Railroad Shops

Oxy-Acetylene and Electric Welding, A. F. Dyer. Welding Engr., vol. 4, no. 1, Jan. 1919, pp. 45-46. Application of these processes at Grand Trunk railway shops.

Spot Welding

Research in Spot Welding of Heavy Plates, W. L. Merrill. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 919-922, 7 figs. Experients pointing to new and enlarged field for spot welding.

Spot Welding and Some of Its Applications to Ship Construction, H. A. Winne. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 923-927, 6 figs. Advantages of spot welding over riveting with respect to strength, time and labor; limitations of spot welding.

Thermit

Modern Welding and Cutting, Ethan Viall. Am. Mach., vol. 50, no. 6, Feb. 6, 1919, pp. 243-248, 6 figs. Thermit welding: its history, nature and uses. First article.

See also RAILROAD ENGINEERING, Shops (Welding); MARINE ENGINEERING, Ships (Welded Ships); Yards (Welding)

VARIA

Inspection and Theory of Probability

Application of the Theory of Probability to the Matter of Inspection (Sull' applicazione del calcolo delle probabilita ad una importante categoria di collaudi), U. Bordoni, L'Elettrotecnica, vol. 5, no. 30, Oct. 25, 1918, pp. 422-430, 8 figs. Mathematical analysis of the problem: what can be asserted of the properties of a number of objects after having examined and tested a determined percentage of the total number.

Silo Granaries

The Equipment of Silo Granaries, R. A. Sidley. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 68-73, 13 figs. General operations carried out in a silo granary.

Tanks, Storage

Round Storage Tanks for Liquids, H. Eisert. Monthly Jl. Engrs. Club of Baltimore, vol. 7, no. 8, Feb. 1919, pp. 155-168, 6 figs. Design formulæ and calculations.

Electrical Engineering

ELECTROCHEMISTRY

Electrolytic Cell

Influence of a Magnetic Field and of a Mechanical Agitation of Electrolyte on the Potential Difference at the Terminals of an Electrolytic Cell (Influence d'un champ magnetique et d'une agitation mécanique du bain sur la difference de potential aux bornes d'une cuve électrolytique), Toshikozu Mashimo. Revue Générale de l'Electricité, vol. 5, no. 1, Jan. 4, 1919, pp. 17-18. Experiments with platinum electrodes in semi-normal solutions of iron chloride. From Memoirs of the College of Science, Kyoto Imperial Univ., vol. 2, no. 6, Oct. 1917, pp. 341-347.

Storage Batteries

Hypothesis Concerning the Action of the Negative Plate in a Lead Storage Battery (Hypothèse sur le fonctionnement de la plaque négative de l'accumulateur au plomb), Ch. Féry. Industrie Electrique, year 27, no. 636, Dec. 25, 1918, pp. 467-468. Experiments with litharge and platinum and electrodes lead author to believe that negative electrode passes to Pb_2SO_4 during discharge.

ELECTRODEPOSITION

Nickel Plating of Cast Iron

Depositing Nickel on Cast Iron from a Hot Electrolyte, Roay F. Clark. Metal Rec. & Electroplater, vol. 4, no. 11, Dec. 1918, pp. 401-402. Results achieved by plater on shears and scissors with data extending over long period; advantages of hot process.

Silver and Gold Refining

Electrolytic Silver and Gold Refining at Perth Amboy, N. J., Geo. G. Griswold. Gen. Meeting Am. Electrochem. Soc., Apr. 3-5, 1919, advance copy, paper 1, pp. 1-7, 8 figs. Refining silver bullion by Moebius process at works of Am. Smelting & Refining Co.; Wohlwill plant for electrolytically refining gold bullion and recovering from it platinum and palladium.

ELECTROPHYSICS

Alternating Currents

Mean Power and Power Factor in a Non-Sinusoidal Alternating-Current Circuit (De la puissance moyenne et du facteur de puissance dans un circuit à courants alternatifs non sinusoïdaux), H. Pécheux. Revue Générale de l'Electricité, vol. 4, no. 22, Nov. 30, 1918, pp. 813-816, 2 figs. Calculation of cos ϕ from oscillographic records. Method followed for determining non-sinusoidal electromotive force is the one published in R. G. E., Feb. 8, 1918.

Cable, Armored, Resistance of

Effective Resistance and Reactance of a Three-Phase Armored Cable to Current Harmonics (Sur la résistance et la réactance effectives d'un cable armé triphasé pour les harmoniques du conrant), R. Swyngedauw. Revue Générale de l'Electricité, vol. 5, no. 1, Jan. 4, 1919, pp. 16-17. Deduces from results of experiments that for third harmonic of fundamental frequency 50 per sec. resistance is comprised between 0.67 and 0.78 ohm per km., and reactance between 0.45 and 0.56 ohm. per km.

Long Conductors

Some Experiments with Long Electrical Conductors, John H. Morecroft. Elecn., vol. 81, no. 2116, Dec. 6, 1918, pp. 658-660, 7 figs. From paper before Inst. of Radio Engrs.

Long-Line Phenomena

Long Line Phenomena and Vector Locus Diagrams, Edy Velander. Elec. World, vol. 73, no. 5, Feb. 1, 1919, pp. 212-216, 12 figs. Long-line transmission problems may be readily solved by the use of rigorous hyperbolic equations of very simple form; an anlysis of equations of this form with vector diagrams for graphical interpretation.

Parallel Conductors

Determination of the Resistance and Impedance of Any Number of Parallel Conductors (Détermination de la résistance et de l'impédance d'un nombre quelconque de conducteurs associés en parallèle), P. de Bancarel. Revue Générale de l'Electricité, vol. 4, no. 26, Dec. 28, 1918, pp. 989-990, 3 figs. Graphical process based on representation of resistances by trigonometric tangents. Simplification of method suggested by Haudié in Revue Générale de l'Electricité, vol. 3, Aug. 31, 1918, p. 297.

Paramagnetism

The Quantum Theory of Paramagnetism (Zum Quantentheorie des Paramagnetismus), Fritz Reiche. Annalen der Physik, Leipzig, vol. 54, no. 22, 1917, pp. 401-436, 7 figs. Discusses the kinetic theory of paramagnetism from the differential equations proposed by Jacobi, Hamilton, and Planck, and compares them with tests made by Kamerlingh Onnes and Oosterhuis.

Quenched Sparks

Processes Occurring in a Quenched Spark (Ueber die Vorgaenge in sogenannten Loeschfunken), V. Pieck. Annalen der Physik, vol. 54, no. 19, pp. 197-244, 14 figs., 3 plates. Relates to electrical vibrations leading to shock. Experiments with various gases at different pressures and with magnesium electrodes. Dynamic theory of quenched sparks. Ions and electrons. Tests at University of Goettingen.

Short-Circuits

Substation Short-Circuits, R. F. Gooding. Elec. Jl., vol. 16, no. 2, Feb. 1919, pp. 61-65, 6 figs. Calculations to determine stresses to which oil circuit breakers, disconnecting switches, bus supports, etc., may be subjected in substations fed by parallel feeders at a time of short circuit. Several typical examples of special systems are selected.

Transverse Magnetization

The Influence of Transverse Magnetization on the Electrical Resistance of Tellurium (Ueber den Einfluss transversaler Magnetisierung auf den elektrischen Widerstand von Tellur), Bengt Beckman. Annalen der Physik, vol. 54, no. 19, 1917, pp. 182-196. Measurements given of the electrical resistance of rods of tellurium and other rare metals at various temperatures.

See also MECHANICAL ENGINEERING, Motor-Car Engineering (Spark Plugs)

FURNACES

Electrically Heated Ovens

Electrically-Heated Ovens. Iron Age, vol. 1003, no. 3, Jan. 16, 1919, pp. 188-189, 2 figs. Construction and operation of enameling ovens; efficiency of different types compared.

Electrically-Heated Ovens. Metal Rec. & Electroplater, vol. 4, no. 11, Dec. 1918, pp. 395-396, 3 figs. Material for walls, insulation, floors; disadvantages of through metal; four general types; efficiency of the various forms.

Metallurgical Furnaces

Electric Furnace Developments, J. Bibby. Iron & Coal Trades Rev., vol. 97, no. 2652, Dec. 27, 1918, pp. 719-722, 7 figs. Abstract of paper before Cleveland Inst. of Engrs.

Application of the Electric Furnace to the Metallurgy of Iron and Its Alloys, H. Etchells. Elecn., vol. 81, no. 2119, Dec. 27, 1918, pp. 734-735. Abstract of paper read before the National Association of Industrial Chemists, November, 1918.

Electric Furnaces for Steel Foundry Work, W. E. Moore. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 76-77. Basic steel recommended on account of possibility of working to closer phosphorus and sulphur limits. Advocates furnace shell of large diameter with shallow bath.

Rennerfelt Furnace

Developments in the Rennerfelt Furnace, H. A. De Fries and Jonas Hertenius. Iron Age, vol. 103, no. 3, Jan. 16, 1919, pp. 190-191, 1 fig. Important changes from original design; side electrodes now tilt; shape of shell is round.

Small Furnaces

Performance of Small Electric Furnace. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 477-479, 9 figs. Operation and equipment of two-ton electric furnace installed at nichrome plant.

GENERATING STATIONS

Canada

Statistical Analysis of the Central Electrical Station Situation of Canada. Contract Rec., vol. 33, no. 5, Jan. 29, 1919, pp. 88-92, 7 figs. From data compiled by Dominion Water Power Branch of Department of the Interior, in cooperation with Bureau of Statistics of Department of Trade and Commerce.

Floating Station

Floating Electric Power Station. Engineering, vol. 106, no. 2762, Dec. 6, 1918, pp. 644-645, 6 figs. Description of flatting power station built and operated during war for providing current for variable conditions overseas where mobility and convenience were of importance.

Legal Liability

Liability of Central Station Company for Failure of Electric Power, Chesla C. Sherlock. Elec. Rev., vol. 74, no. 6, Feb. 8, 1919, pp. 216-217. Several decisions covering the question of power failure, both through negligence of employees of utility company and breach of contract.

Three-Phase-Two-Phase Type

Features of Three-Phase-Two-Phase Generating Station. Elec. Rev., vol. 74, no. 3, Jan. 18, 1919, pp. 85-88, 9 figs. Installation and operation features of Eastern Wisconsin Electric Co.'s Sheboygan plant.

GENERATORS AND MOTORS

Asynchronous Motors

Asynchronous Motor Diagram (Le diagramme des moteurs asynchrones), L. Lagron. Revue Générale de l'Electricité, vol. 4, no. 23, Dec. 7, 1918, pp. 861-863, 1 fig. Indicates method of constructing diagram knowing only value of currents in short-circuit, their angular displacements and resistance of stator and rotor.

Carbon Brushes

Characteristics of Carbon Brushes for Electrical Machinery, Warren C. Kalb. Power, vol. 49, no. 6, Feb. 11, 1919, pp. 202-204, 2 figs. Carrying capacities, contact drop, coefficient of friction, abrasiveness and hardness of carbon brushes defined and methods for determining these characteristics explained.

Cooling

Cooling Electric Motors, D. A. Mossay. Colliery Guardian, vol. 116, no. 3024, Dec. 13, 1918, pp. 1239-1240, 6 figs. From paper before Min. Inst. of Scotland.

Air-Cooled Electrical Search Light (Di uno speciale dispositivo ad arco raffreddato per proiettori di luce), Virgilio Bellini. Elettrotecnica, vol. 5, no. 21, July 25, 1918, pp. 286-287, 1 fig. Rotary positive carbon is cooled by air jet.

Design

The Advantages of Uniform Motor Design, James Burke. Elec. Wld., vol. 73, no. 4, Jan. 25, 1919, pp. 173-175. From a paper the Electric Power Club, Cleveland, Ohio, January, 1919.

Dynamical Theory

The Dynamical Theory of Electric Engines, Llewelyn B. Atkinson. Jl. Instn. Elec. Engrs., vol. 57, no. 277, Dec. 1918, pp. 1-26, 26 figs. Kelvin's ideas concerning mechanical values of distributions of electricity, magnetism and galvanism; energy relations of electric and magnetic systems; constructive fundamental types of electric engines converting electric energy into mechanical work; possible primary types of electric engines; engines converting mechanical work into electrical energy; combined generator and motor cycles; similarity between expressions for efficiencies of ideal electric engines and general form of expression for efficiency of a perfect heat engine. Tenth Kelvin Lecture.

Induction Motors

The Interchangeability of Induction Motors, Gordon Fox. Ry. Elec. Engr., vol. 10, no. 1, Jan. 1919, pp. 5-8, 4 figs. Indicates necessary alterations in windings which will adapt motors for use on currents of different frequency and phase.

Polyphase Induction Motor

Diagram of Polyphase Induction Motors Taking into Account Magnetic Saturation (Diagramme des moteurs polyphasés asynchrones tenant compte de la saturation magnétique), J. Berthenod. Revue Générale de l'Electricité, vol. 4, no. 25, Dec. 21, 1918, pp. 941-946, 6 figs. The various fluxes are reduced to three, a common flux and two others having leakages proportional to primary and secondary currents, respectively; an approximate diagram is thus formed; another diagram is then developed which takes into account actual operating conditions.

Power and Torque

Power and Torque in Electric Motors, Justin Lebovici. Elec. Rev., vol. 74, nos. 4 and 6, Jan. 25 and Feb. 8, 1919, pp. 134-136 and 213-215, 18 figs. Articles discussing principles of different types of motors from a common standpoint; relations in single-phase induction and repulsion motors.

Rebuilding Generators

Rebuilding 25,000-kw. Generator, Thomas Wilson. Power, vol. 49, no. 3, Jan. 21, 1919, pp. 76-79, 11 figs. Account of rebuilding of generator of Commonwealth Edison Co., Chicago, which required upturning of 200-ton unit within space of its own foundation.

Winding

A New Graphic Method for Winding Schemes, L. Fleischmann. Elecn., vol. 81, no. 2117, Dec. 13, 1918, pp. 689-690, 3 figs. Abstract of article in Elektrotechnische Zeitschrift, No. 7, 1918.

LIGHTING AND LAMP MANUFACTURE

Colored Light

Linking Science and Art in Lighting, M. Luckiesh. Elec. Rev., vol. 74, no. 1, Jan. 4, 1919, pp. 14-15. Possibilities of colored light. (Fourth article.)

Home Lighting

Linking Science and Art in Lighting, M. Luckiesh. Elec. Rev., vol. 74, no. 5, Feb. 1, 1919, pp. 171-173, 2 figs. Fifth of a series of six articles. The lighting of a middle-class home.

Light, Measurement of

Photometric Apparatus for Measuring the Illuminating Value of Fluctuating Sources of High Candle Power. Gas Jl., vol. 144, no. 2902, Dec. 24, 1918, p. 658, 3 figs. Tube photometer and supplementary flare photometer which permit measurements of detail revealing power in its relation to rapidly-burning flares of great intensity. From presidential address to Illum. Eng. Soc.

MEASUREMENTS AND TESTS

Boucherot Wheatstone Bridge

On Boucherot's Constant-Current Distributions (Sur les distributions à intensité constante de M. Boucherot), Tr. Lalesco. Revue Générale de l'Electricité, vol. 4, no. 26, Dec. 28, 1918, pp. 987-988, 3 figs. Shows that in Wheatstone-bridge arrangement for transforming constant-potential alternating current into one of constant intensity, it is not necessary that the four resistances be equal and operation may be secured by having two of the branches of equal resistance and opposite sign.

Indicating Instruments, Hysteresis of

The Determinateness of the Hysteresis of Indicating Instruments, F. J. Schlink. Jl. Wash. Acad. Sci., vol. 9, no. 2, Jan. 19, 1919, pp. 38-45, 2 figs. Hysteresis determinations of non-integrating mechanical measuring instruments require no unusual care, and are fully reproducible.

Magnet Testing

Testing Permanent Magnets by Means of a Voltmeter. Elec. Wld., vol. 73, no. 6, Feb. 8, 1919, pp. 267-268, 1 fig. Magnetometer may be devised by modifying a d'Arsonval type voltmeter; descriptions of useful tests.

Porcelain Insulators

Photographic Study of Porcelain Insulators, Harold G. Tufty. Elec. Wld., vol. 73, no. 6, Feb. 8, 1919, pp. 268-271, 3 figs. Polarized light employed in examination of thin sections of insulators some of which have been properly fired while others were underfired and still others overfired; observations on used insulators.

Railway Motor Testing

Railway Motor Testing—II. Elec. Jl., vol. 16, no. 2, Feb. 1919, pp. 76-79, 3 figs. Survey of practical methods accepted by operating companies. Armature testing of standard four-pole lap or two-circuit wound 500-volt railway motors.

Resistance Measuring by Voltmeter

On the Voltmeter Method of Measuring Resistances (Note sur la mesure d'une résistance par la méthode du voltmètre), H. Panchon. Revue Générale de l'Electricité, vol. 4, no. 25, Dec. 25, 1918, p. 972, 1 fig. In formula $X = (E - U)\ R/U$, RE is called K and expression reduced to $(X + R)\ U = K$. The graph presented gives X in terms of U. Discussion of Puget's method in R. G. E. Aug. 31, 1918.

Thermocouples and Pyrometers

Checking Calibration of Thermocouples and Pyrometers. Elec. Rev., vol. 74, no. 2, Jan. 11, 1919, pp. 56-59, 6 figs. Sources of error in thermocouples, pyrometers and leads; methods of testing works units against secondary and works standards; maintenance of standards; apparatus recommended for carrying on work.

Voltage Measurement

The Measure of High Voltages by Means of Klingelfuss Sclerometer (La mesure des hautes voltages au moyen du scléromètre Klingelfuss), Paul Joye. Archives des Sciences Physiques et Naturelles, vol. 46, Nov. 1918, pp. 243-251. An independent third circuit is introduced in induction coil in space which separates right and left portions of secondary winding; this circuit connected to a voltmeter is the sclerometer.

Watt-Hour Meters

Testing Single-Phase Watt-Hour Meters Using a Rotating Standard, P. B. Findley. Power, vol. 49, nos. 4 and 5, Jan. 28 and Feb. 4, 1919, pp. 118-121 and 168-171, 18 figs. Jan. 28: Considers meter used on distributing circuits and method of testing it, using an indicating watt-meter; Feb. 4: Construction of rotating standard watt-meter is described and application to testing single-phase watt-hour meters discussed.

See also RAILROAD ENGINEERING, *Street Railways (Tests)*; ELECTRICAL ENGINEERING, *Transmission, Distribution, Control (Meters)*

POWER APPLICATIONS

Agriculture, Italy

Application of Electricity to Agriculture in Italy (Applicazioni agricole dell' elettricita con riferimento speciale alle condizioni dell' Arzo Romano), D'Escani Alessandro. Annali d'Ingegneria e d'Architettura, year 33, no. 21, Nov. 1, 1918, pp. 330-332. Discusses necessity for wider application of electricity to agriculture, especially for ploughing, threshing, pressing hay and straw, and for pumping water for irrigation purposes.

Coal Mines

The Electric Installations of the Coal Mines in Blackhall, England (Les installations électriques des charbonnages de Blackhall, Angleterre). Génie Civil, vol. 74, no. 1, Jan. 4, 1919, pp. 1-4, 6 figs.

Shop Motors

Light, Electricity and the Shop, C. E. Clewell. Am. Mach., vol. 50, no. 4, Jan. 23, 1919, pp. 163-167, 11 figs. Motors for drilling and boring machines.

Steel-Mill Drives

Electric Steel Mill Drive Developments, Brent Wiley. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 35-37, 5 figs. Consideration given to standardization; variation in mill schedule permitted by flexibility of electric drive; tendency toward central station and 60-cycle apparatus.

GTD

Gages—*Not* Guesses—
Produce Interchangeable Parts

Through the employment of a GTD Limit Gaging System, during the process of manufacture, the percentage of off-size parts reaching the final inspection stage is reduced to a minimum.

By gaging the parts as they are made it is possible to keep the production steady, and the product to size, with a very small amount of scrap.

The use of Limit Gages is the *one* factor absolutely essential to the quantity production of interchangeable parts.

If you make a standard product—
"GAGE IT"
and we'll help you!

Electrically-Driven Plate Mills, G. E. Stoltz. Elec. Jl., vol. 16, no. 2, Feb. 1919, pp. 68-73, 10 figs. Typical steel mill drives; torque curves of induction motor at various r.p.m. rolling plate from slab; graphic chart of load on a 90-in. plate mill; power consumption. Paper read before Phila. Section Assn. Iron & Steel Elec. Engrs.

Modern G. E. Electric Steel Mill Drives. Blast Furnace, vol. 7, no. 1, Jan. 1919, p. 37. Electric drive operating 1200-ton hydraulic bloom shear with rapid acceleration and retardation and distance control.

POWER GENERATION

Hydroelectric Plants

See Power Generation, MECHANICAL ENGINEERING.

See also MARINE ENGINEERING, Ships (Electrical Installation Work; Electric Propulsion); ORGANIZATION AND MANAGEMENT, Transportation (Electric Trucks)

STANDARDS

Aluminum Conductors, Standards for

Proposed Specifications for Aluminum Electrical Conductors (Project de conditions de réception des conducteurs d'électricité en aluminum). Revue Générale de l'Electricité, vol. 4, no. 24, Dec. 24, 1918, pp. 931-933. Preliminary report submitted to l'Union des Syndicats by one of their sub-committees. Report comprises chemical definition, mechanical resistance, modulus of elasticity, flexibility, coefficient of expansion and electrical conductivity of aluminum.

Current and Potential Standards

A New Standard of Current and Potential, Chester T. Allcutt. Elecn., vol. 81, no. 2117, Dec. 13, 1918, pp. 684-685, 6 figs. Abstract of paper before the American Institute of Electrical Engineers.

Standardization Division in Plants

Standardization Division in a Plant Manufacturing Electrical Material (Organisation d'un service d'études des normalisations dans une usine de constructions électriques), J. Fièvez. Revue Générale de l'Electricité, vol. 4, no. 25, Dec. 21, 1918, pp. 975-978, 1 fig. Suggests division, under direction of technical department, to study selection of standards that will meet all conditions which may be required by public. Functions of proposed division and its relation to various other departments are outlined.

Wave-Shape Standards

Review of Work of Sub-Committee on Wave Shape Standard of the Standards Committee, Harold S. Osborne. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 1, Jan. 1919, pp. 1-28, 12 figs. Recommends that for the present the 10 per cent deviation rule should be retained and that trial use should be made of a supplementary wave-shape factor, based on the relation between voltage wave shape and interfering effect in telephone circuits when power and telephone lines parallel each other.

TELEGRAPHY AND TELEPHONY

Cables, Fault Location in

A Useful Arrangement of the Murray Loop Test, L. J. Sell. Post Office Elec. Engrs. Jl., vol. 2, pt. 4, Jan. 1919, pp. 225-228, 3 figs. Applicable in case of cable fault when some wires only are seriously affected and a good wire of same gage and length as faulty wires is available.

Fault Location Tests, J. B. Salmon. Post Office Elec. Engrs. Jl., vol. 2, pt. 4, Jan. 1919, pp. 215-224, 5 figs. Examination of difficulties incidental with location of cable faults by Varley and Murray loop tests, Anderson and Kennelly overlap test and Blavier test. Conditions under which each of these tests is most suitable.

Central Battery System Telephones

Note on the C. B. S. Telephone System. Post Office Elec. Engrs. Jl., vol. 2, pt. 4, Jan. 1919, pp. 197-203, 6 figs. Essential features of central battery system and comparison with present signaling system; study of main characteristics desirable in an exchange designed for local battery talking and automatic calling and clearing.

Multiplex Telegraphy

Modus Operandi of Multiplex Telegraphy. Elec. Rev., vol. 74, no. 2, Jan. 11, 1919, pp. 49-51, 6 figs. Further details concerning principles and application of recently developed system of multiplex telephony and telegraphy; equipment and operation of Washington-Pittsburgh circuit.

Multiplex Telephony

New Multiplex System of Telephony. Elec. World, vol. 73, no. 1, Jan. 4, 1919, pp. 11-13, 5 figs. System developed to increase manifold the message-carrying capacity of long-distance telephone and telegraph wires; suggestive value of earlier undertakings in this field.

Phanoplex

Phanoplex Telegraphy (in Japanese), Y. Fuseno. Denki Gakkwai Zasshi, no. 364, Nov. 18, 1918.

Quadruplex Telegraphy

Morse Quadruplex Working. Post Office Elec. Engrs. Jl., vol. 2, pt. 4, Jan. 1919, pp. 209-214, 2 figs. Discusses conditions under which stable quadruplex working on aerial wires may be contained at all times.

Radio Telephony

Some Aspects of Radio Telephony in Japan, Eitaro Yokoyama. Wireless World, vol. 6, no. 70, Jan. 1919, pp. 569-574, 8 figs. Experiments on influence of electrode materials on discharge and of supply voltage on operation of discharger; static frequency transformer of T. Kujirai (Concluded). From Proc. Inst. Radio Engrs.

The Vision of a Scientist. Wireless World, vol. 6, no. 70, Jan. 1919, pp. 554-57. Remarkable forecasts of Sir William Crooks on wireless telegraphy. From Fortnightly Rev., Feb. 1892.

Sounder Silencers

Sounder Silences, R. T. King. Post Office Elec. Engrs. Jl., vol. 2, pt. 4, Jan. 1919, pp. 206-208, 2 figs. Modification of departmental relay no. 1000A so as to cause bell to ring when distant station holds down key for period of about ten seconds.

Telephone Circuits, Loaded

A Graphical Method of Calculating the Attenuation Constant of Loaded Telephone Circuits, E. S. Ritter. Post Office Elec. Engrs. Jl., vol. 2, pt. 4, Jan. 1919, pp. 187-196, 3 figs. Applicable only to loaded lines, including open wire aerial lines, underground and submarine cable.

Vacuum Tubes

The Development of the Vacuum Valve. Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 20-22, 8 figs. Manufacturing details; uses in the war; importance in wireless telephony.

Developments in Radio Apparatus, George O. Squier. Elec. World., vol. 73, no. 3, Jan. 18, 1919, pp. 129-130. Application to radio communication of vacuum tube; improvements during war; airplane radio-telephone and radio-telegraph sets. From lecture before A. I. E. E. on Aeronautics in the United States from the Beginning of the War to the Present Time.

Theory of the Electric Oscillations in Vacuum Tubes (in Japanese), Y. Nozuki. Denki Gakkwai Zasshi, no. 365, Dec. 10, 1918.

See also ELECTRICAL ENGINEERING, Electrophysics (Quenched Sparks)

TRANSFORMERS, CONVERTERS, FREQUENCY CHANGERS

Charts

Formulæ and Charts Relative to the Working under Load of Industrial Transformers (Formules et abaques relatifs au fonctionnement en charge des transformateurs industriels), L. Dubar. Revue Générale de l'Electricité, vol. 4, no. 22, Nov. 30, 1918, pp. 817-821, 7 figs. Output and voltage drop at various loads and with different angular displacements, obtained from construction data and test results.

Electric-Furnace Transformers

High Intensity Transformers for Electric Furnaces (Etude sur le calcul de transformateurs à forte intensité pour fours électriques), R. Jacquot. Revue Générale de l'Electricité, vol. 4, no. 17, Oct. 26, 1918, pp. 602-617, 2 figs. Classification of transformers used in electrometallurgy; their respective losses and cost.

Oils

Some Characteristics of Transformer Oils, O. H. Eschholz. Elec. Jl., vol. 16, no. 2, Feb. 1919, pp. 74-76, 2 figs. Test figures comparing vapor pressures of transformer oil with those of liquids of well-known characteristics.

Starting Current

Calculation of Starting Current in A. C. Transformers for Electric Traction (Der Einschaltstrom von Wechselstrom-Transformatoren fuer die elektrische Traktion), W. Kummer. Schweiz. Bauzeitung, vol. 72, no. 24, Dec. 14, 1918, p. 233, abstracted from M. Vidmar's article in Elektrotechnik & Maschinenbau, 1918, p. 273. Gives formulæ for calculating the resistance capacity of idle transformers.

TRANSMISSION, DISTRIBUTION, CONTROL

Cables, High Tension

Experimental Investigation of High-Tension Cables, Tsunezo Hada. Denki Gakkwai Zasshi, no. 364, Nov. 10, 1918, 27 pp. 15 figs. Establishes as result of experiments that in a strand cable the minimum potential gradient or the maximum breakdown voltage is practically at position where $D/2h = e$, as in case of a single-core concentric cable.

Distribution Problems

North-Eastern Centre: Chairman's Address, A. P. Pyne. Jl. Instn. Elec. Engrs., vol. 57, no. 277, Dec. 1918, pp. 35-40. Question of generating electricity in bulk and its distribution over wide areas.

Insulators, Line

An Operating View of High-Tension Insulators, P. Ackerman. Elec. World, vol. 73, no. 3, Jan. 18, 1919, pp. 116-119, 4 figs. Severe operating conditions that have caused failure of line insulators; later designs of pin and suspension types promise to solve insulator problem for some years to come.

Application of Theory and Practice to the Design of Transmission Line Insulators, G. I. Gilchrest and T. A. Klinefelter. Elec. Jl., vol. 16, no. 1, Jan. 1919, pp. 8-16, 28 figs. Laboratory tests of various new designs and comparison of these designs with those now in commercial use.

Line Poles

When a Line Pole Needs a Guy, Charles R. Harte. Elec. Ry. Jl., vol. 53, no. 3, Jan. 18, 1919, pp. 139-142, 7 figs. Summary of experience of telephone and power companies as guide to electric-railway transmission-line construction.

Meters

Notes on Demand Meters, H. W. Richardson. Elec. World, vol. 73, no. 5, Feb. 1, 1919, pp. 219-222, 2 figs. Indicating demand meters for small and recording or curve-drawing meters for larger installations; principles upon which modern demand meters operate.

Phase Conversion

The Supply of Single-Phase Power from Three-Phase Systems, Miles Walker. Elecn., vol. 81, no. 2117, Dec. 13, 1918, pp. 682-684, 5 figs. Abstract of paper before the Institution of Electrical Engineers.

Power Conductors

Arrangement of Power Conductors. Jl. Elec., vol. 42, no. 2, Jan. 15, 1919, pp. 72-74, 9 figs. Recommendations for spacing of power lines as made by Cal. Committee on Inductive Interference. Figures and comparisons given apply to non-transposed circuits; comparisons of different configurations hold also for transposed circuits, provided circuits are transposed identically.

Power Control

The Control of Large Amounts of Power, E. B. Wedmore. Power House, vol. 11, no. 12, Dec. 1918, pp. 363-367, 5 figs. Limitation by sectionalizing and employment of feeder or busbar reactances. Paper before Instn. Elec. Engrs. (To be continued.)

Power Factor

Improving Power Factor by Use of Synchronous Motors (Emploi des moteurs synchrones pour ameliorer le facteur de puissance), Paul Rieunier. Revue Générale de l'Electricité, vol. 5, no. 1, Jan. 4, 1919, pp. 3-16, 5 figs. Investigation of the nature and the properties of surface represented by general equation $y = \pm\sqrt{1 - z^2} - xz$, which is a modification of expression $S/R = \sin\phi_1 - \cos\phi_1 \tan\phi_2$ (R. G. E., vol. 4, Nov. 23, 1918, pp. 771-788), where S is current in quadrature supplied by synchronous motor, R current without synchronous motor, and ϕ_1 and ϕ_2 phase angles before and after introduction of synchronous motor respectively; former equation is obtained by making $S/R = y$, $z = \cos\phi_1$, and $x = \tan\phi_2$.

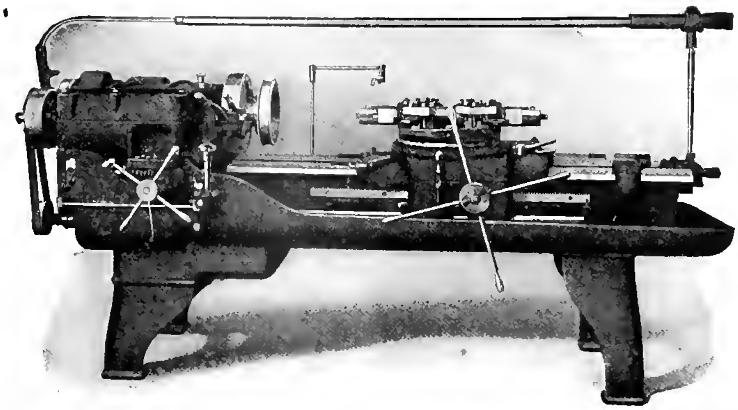
Power Transmission

Latest Developments in the Electric Transmission of Power, P. M. Lincoln. Jl. Cleveland Eng. Soc., vol. 11, no. 3, Nov. 1918, pp. 153-159 and (discussion) pp. 159-161. Limitation of direct-current transmission; early experiments in transmission by alternating current; Tesla's patents in 1889; Mershon's first observations of corona phenomena; the 40,000-volt installation at Telluride Power Co.; recent discoveries concerning nature of coronas.

Relays

The Orling Jet Relay (Le relais Orling à jet), J. Pomey. Revue Générale de l'Electricité, vol. 4, no. 24, Dec. 14, 1918, pp. 899-900, 2 figs. Usage in extensive cable lines of relays constructed on electrocapillary principles.

Hartness Flat Turret Lathes



The Hartness Flat Turret Lathe with cross-sliding head is made in two sizes, and may be furnished with an equipment of tools for either bar work or chuck work, or a double equipment for both bar and chuck work.

The smaller machine is called the 2¼ x 24-inch, and when equipped with the automatic die outfit of tools it turns nearly every conceivable shape from the bar, up to 2¼ inches diameter and 24 inches of length. On chuck work its capacity is 12½ inches diameter or less.

The 3 x 36-inch size handles bars of stock up to 3 inches in diameter, turning pieces up to 36 inches in length. It may also be equipped for chuck work up to 14½ inches in diameter.

SPECIAL FEATURES

The Original Flat Turret

The Flat Turret was put on the market in 1891. Over twelve thousand (12,000) machines equipped with them have been built and sold since, to the great satisfaction of the users. A large, steady tool clamping surface, a circular gib holding the turret down clear around its periphery, a locking pin directly under the cutting point of the tool—all these features combined to set a new standard of output, accuracy and range of work in turret lathe practice.

The unique set of tools employed covered at one leap the evolution from the old-fashioned "screw machine" to the modern turret lathe. It enabled the turret lathe to practically displace the engine lathe on bar, shaft and stud work.

The Cross-Sliding Head

This feature, introduced in 1903, still further extended the field of the turret lathe, making it the standard machine for most chuck work of moderate size. The Cross-Sliding Head has three advantages: (1) It offers a cross-sliding motion, gibbed directly and securely to the bed. There is no piling of slide on slide, no narrow bearing foundation for a lofty superstructure of slide, tool holder and tool. (2) It permits the cross feed to be applied to every tool on the turret if necessary. (3) By allowing a cross adjustment to every tool, complicated and costly special tools are minimized. The regular outfit covers all regular work. The design is so stable that the piloted type of holder is seldom needed.

JONES & LAMSON MACHINE COMPANY

SPRINGFIELD, VERMONT, U. S. A.

109 Queen Victoria Street, London, E. C.

France, Spain and Belgium: F. Auberty & Co., 91 Rue de Maubeuge, Paris
Holland: Spliethoff, Beeuwkes & Co., Rotterdam

SEE OUR DATA IN 1918 A.S.M.E. CONDENSED CATALOGUES OF MECHANICAL EQUIPMENT

A 1

Substations

Automatic Substations on the North Shore Line, Charles H. Jones. Elec. Ry. Jl., vol. 53, no. 2, Jan. 11, 1919, pp. 84-90, 8 figs. Three new substations in operation and another under construction save 177 miles of 500,000-cir. mils cable worth $650,000.

Switches, Oil

Oil Switches (Considérations sur les disjoncteurs à l'huile), W-A. Coales and W-H. Wadmore. Revue Générale de l'Electricité, vol. 4, no. 23, Dec. 7, 1918, pp. 882-887, 7 figs. Provisions which must be made in designing them: their use in connection with time lag relays; characteristic factors; installation.

Wiring, Transmission

Ornamental Electric Transmission Wiring (Zur Aesthetik des Linienbaues bei elektrischen Freileitungen). Dr. P. Neusch-Sigrist. Bern. Schweiz. Elektrotech. Verein Bulletin, vol. 9, no. 12, December 1918, pp. 277-289, 13 figs. Calls attention to the desirability of underground wiring, where feasible, and to the need of using judgment and good taste in the design and location of exposed wire supports.

Civil Engineering

BRIDGES

Aqueduct

Aqueduct Crossing Under the Red River, for Winnipeg Water Supply, J. Armstrong. Contract Rec., vol. 33, no. 4, Jan. 22, 1919, pp. 63-67, 13 figs. Plans, cross section and details. Vertical shafts are 60 ft. deep, horizontal tunnel 1030 ft. long.

Bascule Bridge

138-Ft. Bascule Bridge at the Entrance of La Seyne Port, Toulon Roadstead (Pont basculant de 42 mètres de portée à l'entrée du port de la Seyne rade de Toulon). Génie Civil, vol. 73, no. 23, Dec. 7, 1918, pp. 441-444, 25 figs. Detailed description of new French design in which span is raised to perfectly vertical position by articulated system of levers.

Combination Girder and Arch

An Unusual Bridge Design. Contract Rec., vol. 33, no. 4, Jan. 22, 1919, p. 74, 1 fig. Reinforced concrete structure which is combination of girder and arch design.

Design

Finding the Most Advantageous Construction of a Bridge by Graphical Methods (Die wirtschaftlich guenstigste. Anordnung einer Brueckenanlage auf zeichnerzischem Wege), Prof. Robert Schoenhoefer, Braunschweig. Zeitschrift fuer Bauwesen, vol. 68, no. 10 to 12, 1918, pp. 502-515, 4 figs. Author refers to his book of same title, (1916, Berlin), as well as to 1916 volume of the Zeitschrift, in which he showed the layout for any bridge up to 10 arches. The present work extends this to bridges with any number of arches. The aim is to find the design involving the least cost of construction. The method succeeds where calculations alone would fail.

Long Span

The Reconstruction of a Notable Railroad Bridge. Ry Age, vol. 66, no. 4, Jan. 24, 1919, pp. 238-243, 9 figs. Reconstruction of the Ohio River Crossing at Louisville, containing the longest simple riveted span in the world.

Materials

Data on Concrete and Steel Bridges, John W Towle. Concrete Age, vol. 29, no. 3, Dec. 1918, pp. 16-18. Points out it is best to have shorter spans of concrete, longer ones of steel. Address delivered before North Carolina Good Roads Assn

Steel

Steel Bridge Replacements on the Sydney subdivision of Canadian Government Railways. A. H. Jones. Contract Rec., vol. 33, no. 2, Jan. 8, 1919, pp. 28-30, 6 figs. Account of alterations in masonry piers and replacements of light spans in 16 steel bridges and viaducts

Strengthening

Stokesay Bridge, Shropshire, W. Noble Twelvetrees. Engineering, vol. 107, no. 2766, Jan 3, 1919, pp. 3-6, 17 figs. Strengthening a Telford cast-iron bridge by ferro-concrete arch ribs.

Strengthening a Long Steel Viaduct. Ry. Maintenance Engr., vol. 15, no. 1, Jan 1919, pp. 9-10, 3 figs. Measures taken by Chicago & Eastern Illinois Ry. to reinforce long steel viaduct so as to permit of its use by heavy locomotives.

Stresses

Contraction Stresses in Bridge and Roof Trusses (Von der Schrumpfarbeit am Fachwerk), Leopold Ellerbeck, Berlin. Zeitschrift fuer Bauwesen, vol. 68, no. 10 to 12, 1918, pp. 474-502, 27 figs. Scientific analysis of the distortions found in all kinds of trusses. Considers the forces exerted upon a group of members.

Wilson Bridge, Lyons

The Sejourne System Wilson Bridge at Lyons, France. Eng. & Contracting, vol. 51, no. 4, Jan. 22, 1919, pp. 74-76, 1 fig. Description of certain features of design and construction.

BUILDING AND CONSTRUCTION

Caisson Method

The Caisson Method for Foundations and Mine Shafts. George R. Johnson. Proc. Engrs.' Soc. Western Pa., vol. 34, no. 7, Oct. 1918, pp. 489-514 and (discussion) pp. 514-518, 20 figs. General survey of applications of caisson method in building foundations, bridge piers, and mine shafts, with numerous illustrative examples.

Dams

See Earthwork, Rock Excavation, etc., on page 330.

Floors

Test of a Flat Slab Floor of the Western Newspaper Union Building, Arthur N. Talbot and Harrison F. Gonnerman. Univ. Ill. Bul., vol. 15, no. 39, bul. 106, May 27, 1918, 52 pp., 22 figs. Building was nine years old at time of test. Stresses up to 30,000 lb. sq. in. were developed in reinforcing bars. Information is given extensively on action of slab in its various parts.

Test of a Mixedstone Floor (Essai d'un plancher Mixedstone). Bulletin Technique de la Suisse Romande, year 44, no. 26, Dec. 28, 1918, pp. 233-235, 12 figs. Mixedstone floors are made of separate reinforced concrete standard parts which are placed and cemented together to form a continuous structure. Tests were conducted at University of Paris to ascertain modulus of elasticity, relative flexibility and ultimate strength of this construction.

Heathcote Precast Construction

A New System of Reinforced Concrete Construction. Engineer, vol. 126, no. 3287, Dec. 27, 1918, pp. 551-552, 4 figs. Description of the Heathcote system of precast concrete construction.

Houses

Fifty Double Wall Houses for Carnegie Employees. Concrete, vol. 14, no. 1, Jan. 1919, pp. 24-27, 8 figs. Five-and six-room houses with double 4-in. concrete walls.

281 Fireproof Dwellings Built of Large Precast Concrete Units, Harvey Whipple. Concrete, vol. 14, no. 1, Jan. 1919, pp. 3-8, 26 figs. Layout of housing development and details of houses built at St. Louis for Youngstown Sheet & Tube Co.

Pouring 75 All-Concrete Houses at Phillipsburg, N. J. Concrete, vol. 14, no. 1, Jan. 1919, pp. 9-14 15 figs. Twenty-five houses are of four-room, bath and basement Ingersoll mold and 50 are from new mold producing six-room and bath house. Plans of houses and construction are shown.

Seventy-five Dwellings of Monolithic Concrete at Claymont, Del. Concrete, vol. 14, no. 1, Jan. 1919, pp. 15-19, 19 figs. Plans of four-, five- and six-room houses.

Build 20 All-Concrete Houses: Plan 20 Bungalows. Concrete, vol. 14, no. 1, Jan. 1919, pp. 20-23, 13 figs. Six-room and bath models but with exterior variation in roof and porch treatment to make attractive row.

Joints, Riveted

Rigidity of Riveted Joints of Steel Structures. Engineering, vol. 106, no. 2762, Dec. 6, 1918, pp. 638-640, 9 figs. From Bulletin No. 104, Engineering Experiment Station, Univ. of Ill.

Mill Building

Erecting a Building of Pre-Cast Concrete Units. Contract Rec., vol. 33, no. 3, Jan. 15, 1919, pp. 46-47, 9 figs. Columns, beams and trusses first cast as separate units on the ground and then erected after manner of steel building. Building in question is 160 ft. long, 200 ft. wide and 14 ft. high.

Oil House

Modern Steel Mill Oil House Installation Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 49 and 59, 1 fig. Central distribution point for oil building is of concrete monolithic construction with brick curtain walls and steel sash 62 by 133 ft.

Reservoirs

18,000,000 Gallon Reservoir at Winnipeg. Engineer, vol. 126, no. 3287, Dec. 27, 1918, pp. 545-548, 11 figs. Features of design and construction.

Schools

High School at Ville St. Pierre, P. Q. Contract Rec., vol. 33, no. 1, Jan. 1, 1919, pp. 4-5, 2 figs. Elevation and plan of modern fireproof educational building.

Academy St. Bernard, Shawinigan Falls, Que. Contract Rec., vol. 33, no. 2, Jan. 1, 1919, pp. 8-9, 4 figs. Three-story brick building 140 × 58 ft.

Sewer

Rosedale Creek Sewer Extension, Toronto. Can. Engr., vol. 36, no. 3, Jan. 23, 1919, pp. 163-164, 4 figs. Circular brick sewer 2598 ft. long, 6 ft. 6 in. diameter, one per cent grade. Constructed partly in tunnel using compressed air.

Wing-Wall Abutments

Method and Formulas for Dimensioning Wing Wall Abutments, Benj. L. Parker. Eng. & Contracting, vol. 51, no. 4, Jan. 23, 1919, pp. 80-82, 5 figs.

CEMENT AND CONCRETE

Cement Manufacture, Economies in

Make Cement Cheaper; Save Two Million Tons Coal, F. G. McKelvy. Concrete, Cement Mill Section, vol. 14, no. 1, Jan. 1919, pp. 1-4, 7 figs. Theory and practice of power production by use of exhaust gases from cement kilns. Paper presented before Portland Cement Assn.

Cement, Properties of

Formation and Properties of Blast-Furnace Slag and Portland Cement (La formation et les propriétés des laitiers de haut fourneau et du ciment Portland), B. Neumann. Génie Civil, vol. 73, no. 26, Dec. 28, 1918, pp. 512-513. Chemical constitution and data of industrial value. From Stahl und Eisen, Oct. 17, 1918.

Concrete Strength and Mixing Lime

Effect of Time of Mixing on the Strength of Concrete, Duff A. Abrams. Am. Architect, vols. 114 and 115, nos. 2242, 2243, 2244 and 2246, Dec. 11, 18, 25, 1918 and Jan. 8, 1919, pp. 711-717, 745-750, 775-781 and 85-87, 30 figs. Report of tests conducted at Structural Materials Research Laboratory, Lewis Inst. Tests covered uniformity of machine-mixed concrete; study of time of mixing concrete on its consistency; effect of mix and size of aggregate on mixing time; study of rate of rotation of mixer drum; and effect of temperature of mixing water on strength of concrete. Paper for presentation to Am. Concrete Inst.

Concrete Tile

Making Concrete Tile for Government Housing. Concrete, vol. 14, no. 1, Jan. 1919, pp. 32-34, 4 figs. Concrete wall tile equivalent in volume to 10,000,000 common brick being manufactured for United States Housing Corporation of Department of Labor. Erection, equipment and operation of temporary factory on housing site.

Girder Poles

New Process for the Construction of Reinforced-Concrete Girder Poles (Nouveaux procédés pour la construction de pylones en béton armé), L. Perrin. Génie Civil, vol. 73, no. 23, Dec. 7, 1918, pp. 452-453, 6 figs. Manufactured in pieces of about 10 in. in height and provided with suitable grooves for steel members; when assembled grooves are covered with layer of cement mortar.

Iron Portland Cement

The Use of Iron Portland Cement in Reinforced Concrete, Edwin H. Lewis. Jl. West of Scotland Iron & Steel Inst., vol. 26, part 2, session 1918-1919, pp. 8-11 and (discussion) pp. 11-16, 5 figs. Records of furnace workings which show that in properly made iron portland cement (70 per cent clinker and 30 per cent water-granulated slag) there is no difficulty in keeping sulphur content below requirements of British standard specification.

Pneumatic Method of Concreting

The Pneumatic Method of Concreting, H. B. Kirkland. Contract Rec., vol. 33, no. 2, Jan. 8, 1919, pp. 25-27, 2 figs. Arrangement of plant. Pneumatic method consists in blowing batches of concrete through a pipe from a central point of supplies to their place in the concrete forms. Curve given shows amount of air required to convey concrete various distances.

Reinforced Concrete

The Factor of Safety in Plain and Reinforced-Concrete Bodies Subjected to Uniform and Eccentric Pressures. Based on the Experiments of C. Bach and O. Graf. (Ueber den Sicherheitsgrad von bewehrten und unbewehrten Betonkoerpern, die auf zentrischen und exzentrischen Druck beansprucht werden. Unter Zugrundelegung der Forschungsarbeiten Heft 166-169). Armierten Beton, vol. 11, no. 9, Sept 1918, pp. 174-179, figs. 19 to 24. Mathematical discussion of stresses resulting from eccentric loads. Graphical solution of examples of loading causing deformations. Concluded in vol. 11, no. 10, Oct. 1918, pp. 190-195, figs. 25-27. Maximum compression strength found was 172.6 kg. per cm², maximum tensile strength, 24.9 kg. per cm².

Reinforced Concrete Under Simple Bending Stress (Der auf einfache Biegung beanspruchte Eissenbeton Querschnitt). Max Schendera. Armierter Beton, vol. 11, no. 10, Oct. 1918, pp. 195-199. Calculations, formula and tables pertaining to deflections in slabs. (To be continued.)

Setting Action

Present Knowledge of the Setting Action of Cement and Plasters. Cement & Eng. News, vol. 31, no. 1, Jan. 1919, pp. 22-25. Brief summaries of addresses presented at international discussion of subject held by Faraday Soc. of Lond. From Concrete.

Wasteful Construction

Useless Waste in Concrete Construction Due to Legal Requirements, W. Stuart Tait. Am. Architect, vols. 114 and 115, nos. 2242, 2243, and 2246, Dec. 11, 18, 1918, and Jan. 2, 1919, pp. 717-718, 750-752 and 79-84, 6 figs. Draws attention to developments which have taken place in analytical side of reinforced concrete design and to improvements in materials used; shows that there is now in existence a large force of skilled mechanics and general contractors fitted to construct reinforced concrete, as compared with time when present methods of design and stresses were established. (To be continued.)

Wear of Concrete

The Wearing Resistance of Concrete, Duff A. Abrams. Contract Rec., vol. 33, no. 4, Jan. 22, 1919, p. 77. Methods for determining maximum resistance to wear.

Winter Concreting

Concreting in Cold Weather. Mun. Jl., vol. 46, no. 1, Jan. 4, 1919, pp. 7-8. Suggestions offered by Portland Cement Assn.

See also MECHANICAL ENGINEERING, Pipe (Reinforced-Concrete Pipe)

EARTHWORK, ROCK EXCAVATION, ETC.

Blasting Pole Holes

Digging Pole Holes with Dynamite, C. R. Van Druff. Telephone Engr., vol. 21, no. 1, Jan. 1919, pp. 11-12, 4 figs. Hole is bored with 1.5-in. auger to within 1 ft. of desired depth; then charge is inserted and tamped down with earth and fired by blasting cap and fuse.

Crushed Stone

Standard Sizes of Crushed Stone from the Standpoint of the Producer, R. W. Scherer. Contract Rec., vol. 33, no. 1, Jan. 1, 1919, pp. 11-13. Affirms that standard sizes of crushed stone throughout the states are possible and highly desirable and proposes that nomenclature be confined to stating maximum and minimum sizes. Suggests 3, 2, 1½, 1, ½, ¼ in. as screen sections.

Dams

Hollow Concrete Dam at the Outlet of Lake St. Francois, O. Lefebvre. Contract Rec., vol. 33, no. 3, Jan. 15, 1919, pp. 42-45, 6 figs. Plan, elevation, typical section and details of construction. Project calls for expenditure of $101,000.

Big Eddy Conservation Dam. Can. Engr., vol. 36, no. 2, Jan 9, 1919, pp. 136 and 138. General dimensions of dam under erection at estimated cost of $1,750,000.

The Engineering and Construction of a Concrete Diverting Dam, George M. Bacon. Monthly Jl. Utah Soc. Engrs., vol. 4, no. 11, Nov. 1918, pp. 181-190, 8 figs. Sketch of dam on Boise River, which forms part of Payette-Boise project of U. S. Reclamation Service. River at point of dam has extreme minimum flow of 650 and a maximum of 40,000 cu. ft. per sec.

Reservoir

Building a Reservoir in a Cavernous Country. Ry. Maintenance Engr., vol. 15, no. 1, Jan. 1919, pp. 15-17, 2 figs. How danger of leakage through subterranean channels was avoided.

Steam Shoveling

Steam Shovel Practice, Llewellyn N. Edwards. Can. Engr., vol. 36, no. 2, Jan. 9, 1919, pp. 123-126, 6 figs. Factors upon which economy of operation depends; essential characteristics of efficient operator.

Tunnels

Economics of the C. N. R. Tunnel at Montreal, H. K. Wicksteed. Can. Engr., vol. 36, no. 4, Jan. 23, 1919, pp. 157-162, 5 figs. Problems in location that arose when seeking entrance into that city; observations and incidents regarding construction difficulties. Paper read before Toronto Branch Eng. Inst. Can.

See also RAILROAD ENGINEERING, Permanent Way and Buildings (Landslip)

HARBORS

Hamilton

Recent Harbor Improvement at Hamilton, John Taylor. Contract Rec., vol. 33, no. 3, Jan 22, 1919, pp. 70-72, 4 figs. Completing construction of wharf wall and reclamation of enclosed area behind it.

Quebec

Champlain Dry Dock for Quebec Harbor, U. Valiquet. Engineering, vol. 106, no. 2762, Dec. 6, 1918, pp. 658-662, 16 figs. Illustrated description from paper before Canadian Soc. of Civil Engrs.

Singapore

Recent Harbor and Dock Works at Singapore, Straits Settlements. Engineering, vol. 106, no. 2761, Nov. 29, 1918, pp 603-608, 17 figs. Account of recent developments and improvements.

ROADS AND PAVEMENTS

Bituminous Roads

Bituminous Surfaces in York County, Ont., E. A. James. Can. Engr., vol. 36, no. 3, Jan. 16, 1919, pp. 145-146. Classifies bituminous surfaces into surface mats and wearing surfaces; method followed for each is given. Paper before Ont. Good Roads Assn.

Canada

Width of Provincial Highways, W. A. McLean. Can. Engr., vol. 36, no. 2, Jan. 9, 1919, pp. 131-133, 5 figs. Road sections proposed by Ontario Deputy Minister of Public Highway.

Concrete Roads

The Construction of Concrete Roads, William W. Cox. Contract Rec., vol. 33, no. 3, Jan. 15, 1919, pp. 52-53. Notes on drainage, preparation of subgrade, selection of materials, workmanship and prospection. Paper before Mich. State Good Roads Assn.

Cracking of Concrete Roads and Its Prevention by Reinforcing with Steel, W. B. Sawyer, Jr. Cement & Eng. News, vol. 31, no. 1, Jan. 1919, pp. 28-29. Expansion of concrete by change of temperature; change in moisture content; non-uniform bearing on sub-base; expansion or contraction of sub-base due to change in moisture content; placing reinforcing steel. From Western Eng.

Drainage

Drainage Methods and Foundations for County Roads, E. W. James, Vernon M. Peirce and Charles H. Moorefield. U. S. Department of Agriculture, bul. 724, Dec. 21, 1918, 86 pp., 33 figs. Discussion of important characteristics of different kinds of soils ordinarily encountered in highway construction; proper methods of draining roadbeds constructed of various kinds of soil and under different topographic conditions; explanation of how foundations may be designed to suit soil conditions, road surface and system of drainage.

Engineers, Highway

Engineers for Highway Work, John H. Mullen. Contract Rec., vol. 33, no. 3, Jan. 15, 1919, p. 48. Inadequate pay of highway engineers; qualifications of a highway engineer. From paper before Am. Assn. State Highway Officials.

French Roads

American Methods and Machinery Applicable to Construction and Maintenance of French Highways, Arthur H. Blanchard. Mun. Jl., vol. 46, no. 2, Jan. 11, 1919, pp. 23-32, 16 figs. Restoring of French roads that have been worn out by traffic or destroyed by enemy.

Heavy-Traffic Roads

Notes on Road Construction and Maintenance, Thomas Sawyer Bower. Quarry, vol. 24, no. 263, Jan. 1919, p. 18. Author's experience in regard to securing road which will stand abnormal traffic for long periods. Abstract of paper before Instn. Civil Engrs.

Minnesota Highways

Proposed Highway System for Minnesota. Good Roads, vol. 16, no. 26, Dec. 28, 1918, pp. 249-250, 1 fig. Description of 6000-mile system of main roads proposed by State Highway Department.

National Highways

A National Highway Policy and Plan, E. J. Mehren. Am. City, vol. 20, no. 1, Jan. 1919, pp. 1-5. Plea for selection, construction and maintenance by Federal Government of a national highway system that shall embrace entire country. From address before Joint Highway Congress.

Road Corrugation

Road Corrugation, Ernest Leonard Leeming. Surveyor, vol. 54, no. 1403, Dec. 6, 1918, p. 270. Probable causes; suggestions for preventing or alleviating it. Abstract of paper before Instn. Civil Engrs. Also in Times Eng. Supp., no. 530, Dec. 1918, p. 267.

San Francisco

Street Paving in San Francisco. Mun. Jl., vol. 46, no. 1, Jan. 4, 1919, pp. 1-3, 3 figs. Basalt blocks for heavy traffic, brick for steep grades, asphalt and bituminous concrete for easy grades. Methods of constructing base and wearing surface; grading streets; cost.

Subgrade

Methods for Subgrade Testing on Street Grading Work, E. Earl Glass. Am. City, vol. 20, no. 1, Jan. 1919, pp. 47-48, 2 figs. Use of two 8-ft. rods graduated to feet and tenths from middle as zero, fitted with spikes, and having adjustable targets.

Drainage and Preparation of Subgrade. Concrete Age, vol. 29, no. 3, Dec. 1918, pp. 10-13. Report of Committee on drainage and of subgrade, Nat. Congress on Concrete Road Building.

Wisconsin Highways

Marking and Mapping the Wisconsin Trunk Line Highway System, A. R. Horst. Good Roads, vol. 17, no. 2, Jan. 11, 1919, pp. 13-15, 3 figs. From a paper entitled The Underlying Principles Controlling the Laying Out, Marking and Maintaining of a State Trunk Highway System, presented at joint session of Am. Assn. State Highway Officials and Highway Industries Assn.

SANITARY ENGINEERING

Garbage

Methods of Garbage and Rubbish Collection and Disposal in Larger Cities. Contract Rec., vol. 33, no. 2, Jan. 8, 1919, pp. 32-34. Methods followed in Baltimore, Chicago, Cincinnati, Cleveland, Kansas City, Mo., Milwaukee, Minneapolis, New York, St. Louis and St. Paul.

Sewage-Plant Operation

Instructions for the Operation of State Sewage Plants. Contract Rec., vol. 33, no. 2, Jan. 8, 1919, pp. 35-37. Bulletin prepared by Bureau of Sanitary Engineers and issued by Texas State Board of Health.

Biological Purification of City Sewage (Die Klaeranlage der staedtischen Kanalisation in St. Gallen). Schweiz. Bauzeitung, vol. 72, no. 24, Dec. 14, 1918, pp. 231-233, 6 figs. Technical description of sewage purification plant for 60,000 inhabitants. The drip system used in conjunction with a small river. (To be concluded.)

Sewer Construction

Rideau River Intercepting Sewer, Ottawa, L. McLaren. Contract Rec., vol. 33, no. 2, Jan. 8, 1919, pp. 21-24, 9 figs. Design and construction of interceptor which will drain 1060 acres.

Some Sewer Construction Details. Mun. Jl., vol. 45, no. 26, Dec. 28, 1918, pp. 501-502, 2 figs. Laying a sewer above street grade; excavating and laying sewer in deep trench in sand and water.

WATER SUPPLY

Meters

Sizes of Service Meters, W. R. Edwards. Mun. Jl., vol. 46, no. 1, Jan. 4, 1919, pp. 4-5. Practices and experience of Passaic Water Co. in use of meters, specially in regard to desirable sizes. Paper before N. Y. Section, Am. Water Works Assn.

Pipe Maintenance

Lead Pipe Couplings, J. A. Jensen. Jl. Am. Water Works Assn., vol. 5, no. 4, Dec. 1918, pp. 407-411. Examples of water loss to municipality on account of service leaks occurring between water main and meter; results of experimental examination of conditions developing leaks.

Cold Weather and Mains in Duluth. Mun. Jl., vol. 46, no. 1, Jan. 4, 1919, pp. 6-7. Experience with freezing and thawing by electricity.

Water Main Cleaning in St. Louis. Mun. Jl., vol. 46, no. 1, Jan. 4, 1919, pp. 5-6, 4 figs. Methods and results in cleaning 50 miles of mains.

Dependable Power

DEPENDABLE POWER

Midwest Engine Company Products

Midwest—Diesel Engines
Midwest—Hvid Oil Engines
Midwest—Parsons Turbines (Reaction Type)
Midwest—Wait Turbines (Impulse Type)
Midwest—Hill Centrifugal and Reciprocating Pumps and Auxiliaries
Werkspoor Diesel American Licensees

MR. MILL OWNER—you know that it is impossible to secure any machinery that will not require some supervision in operation, but if you are on the lookout for apparatus that will give long and faithful service with a minimum of supervision, it will pay you to investigate Midwest products.

Take the Midwest pump and turbine shown here for example. They are constructed in the simplest possible manner, yet with the highest efficiency and the greatest rugged strength. You can put them in operation and run them for years with but the slightest amount of supervision.

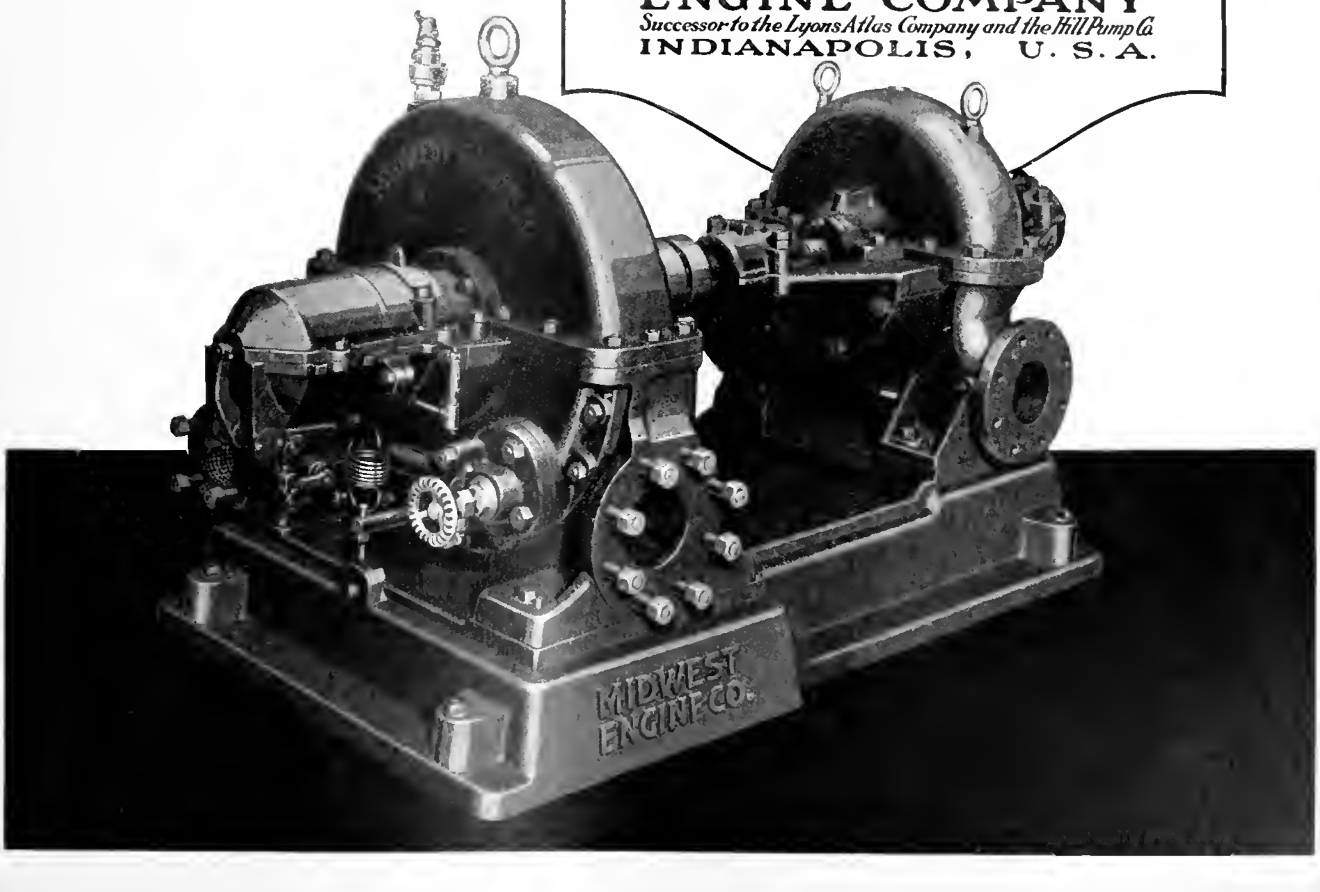
They comprise the least possible number of wearing parts, are so well balanced, both statically and dynamically, that there is absolutely no vibration. Particularly desirable where exhaust steam can be utilized for heating or cooking.

We stand behind every Midwest product to the limit; our Service Department is at your disposal at all times; and it is our creed that the sale begins rather than ends when the installation is made.

Midwest turbines are produced in all sizes from 5 H. P. to 1000 H. P.—pumps in all sizes and types from 1-inch to 42-inch.

Let our engineers assist you in solving your hydraulic problems. Quotations on any type steam turbine or pump on request.

MIDWEST
ENGINE COMPANY
Successor to the Lyons Atlas Company and the Hill Pump Co.
INDIANAPOLIS, U. S. A.



Reservoirs

Waterworks Operation: Maintenance of Reservoirs. Mun. Jl., vol. 45, no. 26, Dec. 28, 1918, pp. 506-507; vol. 46, no. 1, Jan. 4, 1919, pp. 10-12. Dec. 28: Features of maintenance of small reservoirs and of large impounding reservoirs, sodding and other treatment of embankments; Jan. 4: Causes of leakage from reservoirs, their location, stopping them by use of cement, asphalt, clay, etc. (To be continued.)

Construction Methods Employed in Building the New Intake and Remodeled Reservoirs of the Oshkosh, Wis., Water Works, T. B. Jorgensen. Cement & Eng. News, vol. 31, no. 1, Jan. 1919, pp. 26-27, 3 figs. Intake consists of 300 ft. of piping connecting shore line with suction well in filtration plant, and 1200 ft. of piping from shore line out in Lake Winnebago. It is constructed of 24-in. cast-iron piping.

Water Mains, Protection of

Protecting Water Mains, Fire Hydrants and Valves Against Freezing in Winnipeg, F. H. Hooper. Contract Rec., vol. 33, no. 1, Jan. 1, 1919, p. 3. Paper before Nat. Fire Protection Assn.

Water Purification

St. Louis Water Purification Plant. Mun. Jl., vol. 45, no. 26, Dec. 28, 1918, pp. 503-505. Amounts and prices of chemical used; methods and results of operation; cleaning filter sand; effects of chemicals on apparatus; itemized cost of operating plant.

Water Storage

Advantages and Disadvantages of the Storage of Water, Melville C. Whipple. Contract Rec., vol. 33, no. 2, Jan. 1, 1919, pp. 6-7. Claims that storage of surface water affords effectual means for safeguarding its hygienic quality and indicates means to overcome increase of color and production of tastes and odors from growth of microscopic organisms.

WATERWAYS

Georgian Bay Canal

The Georgian Bay Canal, J. J. Bell. Engineer, vol. 126, no. 3286, Dec. 20, 1918, pp. 527-528, 8 figs. Description of proposed Canadian canal connecting Georgian Bay with the St. Lawrence at Montreal.

Interior Navigation

Notes in Interior Navigation of Various Countries (Apuntes sobre la navegacion interior en algunos paises), Carlos Mendoza. Revista de Obras Publicas, year 66, nos. 2256 and 2257, Dec. 19 and 26, 1918, pp. 625-630 and 637-640. Dec. 19: Economical aspect of inland water transportation and railway construction in development of present network of canals and navigable rivers in France; Dec. 26: Data on navigable courses in England, United States, Germany and Italy. (Concluded.)

Italy

The Port of Ostia Nuova, near Rome, and the Railway from Ostia to Rome (Le port d'Ostia Nuova, près de Rome et le chemin de fer d'Ostia à Rome). Génie Civil, vol. 74, no. 1, Jan. 4, 1919, pp. 12-13, 2 figs. Project to build navigable canal connecting Rome and Ostia Nuova.

U. S. Rules for Water Transportation

Rivers. General Rules and Regulations Prescribed by the Board of Supervising Inspectors as Amended at Board Meeting of January 1918, and further Amended by Action of Executive Committee of the Board of Supervising Inspectors, Meetings of March 15, April 3, May 11, June 5, August 5, and September 24, 1918. Department of Commerce, Steamboat-Inspection Service, form 801D, Nov. 19, 1918, 145 pp. 5 figs. Concerning boilers, attachments, boats, rafts, fire apparatus, ferryboats, barges, lifeboats, steam pumps, safety valves, etc.

MUNICIPAL ENGINEERING

Town Planning

Town-Planning in New Zealand, A. G. Waller. Jl. Am. Inst. Architects, vol. 6, no. 12, Dec. 1918, pp. 567-577. Résumé of town-planning bill; conditions of trade, wealth and production in New Zealand; significance of town-planning in architectural developments.

Relation of the Curve to Town-Planning, H. L. Seymour. Can. Engr., vol. 36, no. 2, Jan. 9, 1919, pp. 119-121, 4 figs. Discussion of methods employed in laying out curves for streets or lot lines.

Mining Engineering

BASE MATERIALS

Rock Quarrying

Rock Quarrying for Cement Manufacturing, Oliver Bowles. Stone, vol. 40, no. 1, Jan. 1919, pp. 19-21, 2 figs. Efficiency and safety under modern conditions of operation. From Bureau of Mines bulletin.

COAL AND COKE

Coal Oxidation and Ignition

The Oxidation and Ignition of Coal, Richard Vernon Wheeler. Jl. Chem. Soc., vols. 113 and 114, no. 674, Dec. 1918, pp. 945-955, 2 figs. Account of work carried out during past nine years by British Coal Dust Experiments Committee, Min. Assn. Great Britain. Hypothesis is advanced that reaction responsible for self-heating of coal is mainly attachment of oxygen to molecules of high carbon content, and subsidiary to this, interaction oxygen thus loosely held, by carbon-like molecules, and other atoms or those molecules, or other portions of coal conglomerate.

Coal Production

Coal—Now and Next Year, C. E. Lesher. Coal Age, vol. 15, no. 3, Jan. 16, 1919, pp. 99-104, 4 figs. Statistics of production and consumption.

Coke-Oven Gas

Washing Light Oil Fractions from Coke Oven Gas, F. D. Schreiber. Gas Age, vol. 43, no. 1, Jan. 1, 1919, pp. 22-24, 1 fig. Suggestions from general foreman of benzol plant.

Coke Plant Producing Gas for Domestic Purposes. Gas Age, vol. 43, no. 1, Jan. 1, 1919, pp. 11-12, 3 figs. Example of by-product coking practice. Plant consists of 65 Koppers cross-regenerative ovens (12¼ tons) with capacity of 1200 tons coal per day and is complete for recovery of gas, tar, ammonia and benzols.

Coke-Oven Gas and the Demand for Cheap Fuel. Gas Age, vol. 43, no. 1, Jan. 1, 1919, pp. 16-17. Extent of coke production in ovens and in beehive ovens; importance of metering gas.

Chester Producer Fired By-Product Coke Ovens, J. D. Shattuck. Gas Age, vol. 43, no. 1, Jan. 1, 1919, pp. 7-10, 6 figs. Operation of Philadelphia Gas & Elec. Co. plant for production of city gas and also for recovery of by-products.

Coke Ovens

Economic Considerations in Coke Oven Practice, W. Colquhoun. Colliery Guardian, vol. 116, no. 3020, Nov. 15, 1918, pp. 1022-1024. From paper before Midland Inst. of Civ. Min. and Mech. Engs., Nov. 1918. Also in Iron & Coal Trades Rev., vol. 97, no. 2647, Nov. 15, 1918, pp. 541-543.

Change in Beehive Coke Oven Construction Due to Mechanical Operation, George W. Harris. Coal Age, vol. 15, no. 2, Jan. 9, 1919, pp. 44-48, 12 figs. Details of coke ovens for mechanical operation.

A New Coke Oven Installation. Engineer, vol. 126, no. 3282, Nov. 22, 1918, pp. 430-432, 5 figs. Description of battery of thirty-seven 12-ton Semet-Solvay coke ovens with washer and by-product recovery plant at one of plants of Newton, Chambers & Co., Ltd.

Economic Considerations in Coke Oven Practice, W. Colquhoun. Gas World (Coking Section), vol. 69, no. 1794, Dec. 7, 1918, pp. 19-20. Deficiencies in present application of heat necessary to distil coal; advantages of hot direct-recovery process. Paper before Midland Inst. Min. Engrs.

Republic By-Product Coke Plant at Youngstown. Gas Age, vol. 43, no. 1, Jan. 1, 1919, pp. 13-15, 5 figs. Brief description of by-product coke-oven installation of 143 Koppers ovens, producing gas and coke for use in steel manufacture.

Plant of the Seaboard By-Product Coke Company, D. MacArthur. Gas Age, vol. 43, no. 1, Jan. 1, 1919, pp. 1-6, 9 figs. Oven installation consists of 165 Koppers ovens subdivided into three units. Daily capacity is 3000 tons of coal, yielding 2200 tons coke, 16½ million cubic feet surplus gas of 610 B.t.u. quality, 75,000 lb. ammonium sulphate, 24,000 gal. tar and 10,000 gal. light oil. (To be continued.)

Insulation for By-Product Coke Ovens, P. A. Boeck. Gas Age, vol. 43, no. 1, Jan. 1, 1919, pp. 24-26, 5 figs. How insulating bricks are placed in wall; heat gradient and saving due to heat insulation; advantages of insulation.

Rail Transportation

Railroad Readjustment Problems Confront Coal Operators, John Callahan. Coal Trade Jl., year 51, no. 3, Jan. 15, 1919, pp. 51-52. How mining is affected by transportation control as well as by maintenance or modifications of existing regulations.

ORE DRESSING

Tube and Ball Mills

Notes on Ore Dressing, A. W. Allen. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 100-102. Efficiency of tube mills; progress in ball-milling practice.

GEOLOGY AND MINERALOGY

Earth Movements

Earth Movements. Jl. Chem. Metallurgical & Min. Soc. S. A., vol. 19, no. 1, Oct. 1918, pp. 63-66. Analysis of probable causes which operated in movement of ground at Great Boulder mine. From Jl. Chamber of Mines of W. Australia.

Igneous Differentiation

A Type of Igneous Differentiation, Frank F. Grout. Jl. Geol., vol. 26, no. 7, Oct-Nov., 1918, pp. 626-658, 12 figs. Rocks of Duluth gabbro lopolith are found to fall into two series, one related to gabbro family, other more closely to granites.

Manganese Dioxide Banding

Rythmic Banding of Manganese Dioxide in Rhyolite Tuff, W. A. Tarr. Jl. Geol., vol. 26, no. 7, Oct-Nov. 1918, pp. 610-617, 5 figs. Explains origin of eccentric structures of manganese dioxide found near Tucson, Ariz., by manganese dioxide being derived from mineral located at nucleus of structure and being precipitated in successive rings by rhythmic precipitation following mingling of outwardly moving manganese solution with one of oxidizing character.

Radiolarian Charts

The Radiolarian Cherts of the Franciscan Group, E. F. Davis. Univ. Cal. Publications, Bul. Dept. Geol., vol. 11, no. 3, Dec. 23, 1918, pp. 235-432, 30 figs. Results of investigation to determine their origin.

Rock Diagrams

A Form of Multiple Rock Diagrams, Frank F. Grout. Jl. Geol., vol. 26, no. 7, Oct-Nov. 1918, pp. 622-625, 3 figs. Modification of Adams' method. Individual rock diagrams are not plastered but clamped into position leaving them free for rearrangement as they are studied from various points of view.

Tear Figures and Minerals

Tear-Figures on Certain Minerals, Mikio Kuhara. Memoirs College of Eng., Kyoto Imperial Univ., vol. 2, nos. 2 and 3, July and Nov. 1918, pp. 53-62 and 71-82, 45 figs. July: Characteristics on tear-figures on aragonite, alum and borax; Nov.: Characteristics on tear-figures on minerals belonging to tetragonal and triclinic systems, wulfenite and copper-sulphate crystals were selected as representatives of these systems.

IRON

Belcher Islands' Deposits

Iron Deposits on the Belcher Islands, Hudson Bay, E. S. Moore. Monthly Bul. Can. Min. Inst., no. 82, Feb. 1919, pp. 196-206, 4 figs. Topographic features and geology; photomicrographs of granules from iron field; results of analysis of sample.

Production

World's Division of Iron Analyzed, A. J. Hain. Iron Trade Rev., vol. 64, no. 1, Jan. 2, 1919, pp. 28-32, 3 figs. Pig-iron and steel production in United States, United Kingdom, France and Germany for years 1913-1918.

COPPER

Kennecott District

Mining Copper at Kennecott, Alaska. Min. & Sci. Press, vol. 118, no. 2, Jan. 11, 1919, pp. 53-56, 3 figs. Mining possibilities.

Mineral Determination

Sulphur Dioxide Method for Determining Copper Minerals in Partly Oxidized Ores, Charles E. Van Barneveld and Edmund S. Leaver. Department of Interior, Bur. of Mines, tech. paper 198, 14 pp., 1 fig. Sources of error in sulphuric acid method and ammonia method for selective determination of copper minerals; procedure in sodium tartrate method; sulphur dioxide method; results of leaching chalcocite and chalcopyrite with 5 per cent solution of different reagents; results with four methods compared.

Utah

The Utah Copper Enterprise—IX, T. A. Rickard. Min. & Sci. Press, vol. 117, no. 26, Dec. 28, 1918, pp. 853-860, 9 figs. Smelting of concentrate at Garfield smelter of Am. Smelting & Refining Co.

LEAD

Hydrometallurgy

Innovations in the Metallurgy of Lead, Dorsey A. Lyon and Oliver C. Ralston. Department of Interior, Bur. of Mines, bul. 157, 1918, 176 pp., 13 figs. Application of new hydrometallurgical and other methods. Results of experiments conducted by Salt Lake City station of Bur. of Mines in coöperation with department of metallurgical research, Univ. of Utah.

Smelting

Metallurgy of Lead, H. O. Hofman. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 88-90. Lead smelting practice; modern silver-lead smeltery.

MAJOR INDUSTRIAL MATERIALS

Manganese

Electric Smelting on the Pacific Coast, W. L. Morrison. Jl. Elec., vol. 42, no. 2, Jan. 15, 1919, pp. 67-68. States that while absence of cheap power precludes general development of electric furnace, nevertheless there is real opportunity in electric smelting of silicon manganese.

Metallurgical Investigations During 1918, Van H. Manning. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 65-67. Production of ferromanganese; smelting low-grade manganese ores in electric furnace; use of low-grade iron; problems studied by Bureau of Mines.

Manganese Deposits of East Tennessee—II, G. W. Stose and F. C. Schrader. Resources of Tennessee, vol. 8, no. 4, Oct. 1918, pp. 235-324, 14 figs. Report prepared under coöperative agreement between State Geol. Survey and U. S. Geol. Survey.

Nickel

A Process for Electrolytically Refining Nickel, Geo. A. Guess. Gen. Meeting Am. Electrochem. Soc., Apr. 3-5, 1919, advance copy, paper 2, pp. 9-12. Impure nickel containing copper and iron is used as anode; both iron and copper go into solution, but copper is precipitated by keeping powdered calcium carbonate suspended in electrolyte; cathode is enclosed in canvas bag; glue is used in solution.

Zinc

Metallurgy of Zinc, W. E. Ingalls. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 87-88. Roasting; distillation furnaces; distilling practice.

Foreign Zinc-Smelting Capacities and Prospects, W. R. Ingalls. Eng. & Min. Jl., vol. 107, no. 5, Feb. 1, 1919, pp. 227-228. Refers particularly to England, Australia, Belgium and Silesia.

MINES AND MINING

Cars, Mine

Standardization of Mine Cars in Metal Mines, R. M. Raymond. Eng & Min. Jl., vol. 107, no. 5, Feb. 1, 1919, pp. 220-224, 9 figs. Paper read at Seventh Annual Safety Congress, Nat. Safety Council.

Cement Gun

Use of the Cement Gun in a Bituminous Coal Mine, M. S. Sloman. Mine & Quarry, vol. 11, no. 1, Nov. 1918, pp. 1092-1095, 2 figs. Results of United Coal Corporation said to prove that a cement coating properly applied will form permanent barrier to action of weathering on roofs susceptible to air slacking; gives cost figures.

Drilling

The Technique of Diamond-Drilling, J. A. MacVicar. Min. Mag., vol. 20, no. 1, Jan. 1919, pp. 18-25. History and utility of the diamond-drill; patent specifications of Leschot diamond-drilling apparatus; operations followed in process of drilling; recent uses of diamond-drills in testing of foundations for dam sites. Paper read before Cornish Inst. Engrs.

Hammer Drills—Their History, Design and Operation, Henry S. Potter. Jl. S. A. Instn. Engrs., vol. 17, no. 4-5, Nov.-Dec. 1918, pp. 68-80, 17 figs. Refers especially to the popular jack hammer type. (To be concluded.)

The Hand Hammer Drill, James P. Cotter. Monthly Bul. Can. Min. Inst., no. 82, Feb. 1919, pp. 207-211. Purpose in applying water and air to bottom of drill hole while drilling; uses of hammer drill in coal mines.

Hydraulic Stowing

Primary Considerations in Hydraulic Stowing, C. A. John Hendry. Colliery Guardian, vol. 116, no. 3016, Oct. 18, 1918, pp. 805-807, 14 figs. From paper before Geol. and Min. Soc. of India.

Inspection, Idaho

Mining in Idaho in 1918, R. N. Bell. Eng. & Min. Jl., vol. 107, no. 5, Feb. 1, 1919, pp. 236-238. Account of State inspection of mines.

Laws

Collection of Laws, Decrees, Resolutions and Other Acts Concerning Mines, Quarries, Sources of Mineral Waters, Steam Apparatus and Railroad Exploitation (Recueil de lois, décrets, arrêtés et autres actes concernant les mines, les carrieres, les sources d'eaux minerales, les appareils à vapeur et l'exploitation des chemins de fer). Annales des Mines, Partie Administrative, series 11, vol. 7, 1918, pp. 81-185. Documents of second quarter of 1918 issued by Ministry of Public Works, France.

Prospecting

Hydraulic Prospecting at the Rooiberg Tin Mines, E. R. Schoch. Jl. S. A. Instn. Engrs., vol 17, no. 4-5, Nov.-Dec., 1918, pp. 61-67, 9 figs. Surface prospecting by means of hydraulic jets or monitors on level ground with artificially conserved return water.

Utah

Mining in Utah in 1918, Edward R. Zalinski. Eng. & Min. Jl., vol. 107, no. 4, Jan. 25, 1919, pp. 178-183.

1918 British Columbia

Mining in British Columbia in 1918, Robert Dunn. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11. 1919, pp. 110-111.

1918 U. S.

General Review of Mining in the United States in 1918. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 103-107.

See also MECHANICAL ENGINEERING, Handling of Materials (Coal Handling, Coke.)

MINOR INDUSTRIAL MINERALS

Graphite

Alabama Graphite in 1918, W. F. Prouty. Eng. & Min. Jl., vol. 107, no. 4, Jan. 25, 1919, pp. 194-195. Processes in milling; classification of washers; costs.

Monazite

Monazite as a Source of Incandescent Light-ing Material, Sydney J. Johnstone. Gas World, vol. 69, no. 1794, Dec. 7, 1918, pp. 350-351. Sources and history of mineral monazite from which are obtained the rare earths composing luminous portion of incandescent gas mantle. From Jl. Soc. Chem. Indus.

Molybdenum

Molybdenum Within the Empire, Sydney J. Johnstone. Jl. Soc. Chem. Indus., vol. 37, no. 23, Dec. 16, 1918, pp. 448R-450R. Statistics of world production and particularly of progress in mines throughout British Empire.

Tungsten

The Tungsten Industry in 1918, Geo. J. Young. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 78-80. Difficulties of mining; inconvenience of not having standard specifications for buying tungsten ores; domestic and total world production figures.

Tungsten and the War, Julius L. F. Vogel. Min. Mag., vol. 20, no. 1, Jan. 1919, pp. 12-17. Qualities possessed by high speed tungsten steel; development of tungsten industry in Great Britain; manufacture of tungsten.

The Occurrence, Chemistry, Metallurgy and Uses of Tungsten, with Special Reference to the Black Hills of South Dakota, J. J. Runner and M. L. Hartmann. South Dakota School of Mines, bul. 12, Departments of Geol. & Chem., Sept. 1918, pp. 1-159 and 257-262, 20 figs. Parts relating to deposits of Black Hills are the result of field work and laboratory research of authors.

A Bibliography of Tungsten Mines, Louis Hartmann. South Dakota School of Mines, bul. 12, Departments of Geol. & Chem., Sept. 1918, pp. 160-255 and 262-264.

Tungsten and Molybdenum

Manufacture of Tungsten and Molybdenum, Paul McJunkin. Am. Mach., vol. 50, no. 3, Jan. 16, 1919, pp. 99-100. How tungsten wire is made; coiling the spiral; properties; applications; use of tungsten disks in wireless apparatus; development of X-ray; tungsten wire data.

Vanadium

Analysis of Vanadium in the Ferrovanadiums (Método de valoración del vanadio en los ferrovanadios), Vicente García Rodeja. Boletín de Minas, vol. 10, nos. 7-9, Sept. 30, 1918, pp. 122-128. Survey of methods in use; special reference to Slavig method by treatment with nitric and hydrochloric acids; fusion method of Pinerúa (reagent is sodium bi-oxide).

OIL AND GAS

Crude Oil Production

Production of Crude Oil at New High Level. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 154-157, 2 figs. Exports of all mineral-oil products except kerosene show steady increase for 21 years.

The Passing of Petroleum. Engineering, vol. 106, no. 2762, Dec. 6, 1918, pp. 633-635, 3 figs. Review of present situation.

Petroleum — A Resource Interpretation, Chester G. Gilbert and Joseph E. Pogue. Jl. Soc. Automotive Engrs., vol. 4, no. 2, Feb. 1919, pp. 100-110, 4 figs. Discussion of available resources and their conservation.

Gasoline

Making Gasoline from Gas. Motor Boating, vol. 23, no. 1, Jan. 1919, pp. 13-14 and 47, 2 figs. General arrangement of apparatus employed in process of recovering gasoline from casing-head gas.

Determining Gasoline in Natural Gas, W. P. Dykema and Roy C. Neal. Automotive Industries, vol. 40, no. 2, Jan. 9, 1919, pp. 57-59, 2 figs. Method evolved at Bartlesville Experiment Station, Bureau of Mines.

Testing Gas for Its Gasoline Content, W. P. Dykema and Roy C. Neal. Oil and Gas Jl., vol. 17, no. 32, Jan. 10, 1919, pp. 42 and 44, 2 figs. Absorption apparatus developed by Bureau of Mines experts.

Mexico

Mexico as a Source of Petroleum and Its Products, R. De Golyer. Jl. Soc. Automotive Engrs., vol. 4, no. 2, Feb. 1919, pp. 74-76. Estimates of reserves in Mexican oil fields; development since 1910; present conditions.

Oil Recovery

Production of Oil from Mineral Sources, F. Mollwo Perkin. Gas Jl., vol. 144, no. 2902, Dec. 24, 1918, pp. 658-660. When to use high or low temperature for carbonizing bituminous material. Paper read before Instn. Petroleum Technologists.

Petroleum Industry

Some General Observations on the Petroleum Industry, V. H. Manning. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 35-38, 2 figs. Coöperation between Bur. of Mines and petroleum industry; possible technical research work; utilization of oil shales; foreign supply situation. From address by Director, Bur. of Mines, before Reconstruction Conference of Indus. War Service Committees.

Shale

Commercial Possibilities of Oil Shale, Harry J. Wolf. Eng. & Min. Jl., vol. 107, no. 5, Feb. 1, 1919, pp. 217-219, 2 figs. Oil-bearing shales in Colorado and Utah and their present development; methods of mining and milling, comparison with Scottish shale deposits.

Water, Shutting Off

Methods of Shutting Off Water in Oil and Gas Wells, F. B. Tough. Department of Interior, Bur. of Mines, bul. 163, 122 pp., 27 figs. Summarizes existing knowledge of methods and devices for protecting oil or gas sands from encroachment of water; California laws relating to protection of natural resources of petroleum and natural gas flow. Also in Water & Gas Rev., vol. 29, no. 7, Jan. 1919, pp. 28-29.

One of the Problems Involved in Excluding Water from Oil or Gas Wells, F. B. Tough. Water & Gas Rev., vol. 29, no. 7, Jan. 1919, pp. 28-29. Making watertight joint between string of casing and wall of hole at impervious stratum above productive sands and below water horizons; formulæ for collapsing pressures of modern lay-welded bessemer-steel tubes.

PRECIOUS MINERALS

Gold

The Value of Gold in the Economic System, Henry Strakosch. Min. & Sci. Press, vol. 117, no. 26, Dec. 28, 1918, pp. 861-863. Classifies gold mines and suggests means for stimulating production of gold.

The Gold Problem. Min. Mag., vol. 20, no. 1, Jan. 1919, pp. 28-31. Report of the British Government committee, appointed to investigate problem of maintaining output of gold in face of increasing costs at mines.

822 POWER Vol. 48, No. 23

Coal Saving by the Scientific Control of Steam Boiler Plants*

BY D. BROWNLIE

THE author has been associated for about ten years with the investigation on scientific lines of the working of every description of steam-boiler plant, and in the present article it is proposed to give the average figures for 250 typical steam boiler plants, with the object of supplying accurate data as to the tremendous national economy that can be effected by the adoption of scientific methods in the boiler-house.

In the burning of coal for the generation of steam, the loss because of lack of scientific methods is hardly realized and, apart from the national point of view, offers to the individual firm a means of most substantial economy in running expenses.

Economizers—Out of the 250 plants, 155 were fitted with economizers, the other 95 plants having no means of utilizing the waste heat from the boiler flues.

Taking the 155 plants fitted with economizers, the average saving is 11.4 per cent. of the coal bill. The highest figure found was 19 per cent. on a cotton-mill plant. The ordinary figure obtained on a well-managed plant is 15 to 20 per cent. saving, depending on the conditions.

Power
December 3, 1918

Engineers sometimes question the claims of the manufacturers regarding the savings made by their apparatus.

GREEN'S FUEL ECONOMIZERS

do show large savings and we quote above some very interesting figures by Mr. Brownlie. These are the result of ten years' experience and detailed tests on 250 steam plants.

We think you will agree with us that these fully substantiate the statements that we have made in our advertising.

Our Engineers will be glad to tell you what savings Economizers can make in your plant.

THE GREEN FUEL ECONOMIZER Co.
BEACON, N.Y.

Gold and Silver

Metallurgy of Gold and Silver, A. W. Allen. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 92-96. Amalgamation practice; reinstatement of charcoal as precipitant; South African metallurgical progress; gold extraction with colloidal carbon; refining gold bullion; sodium sulphide in cyaniding.

RARE MINERALS

Radium

How Radium-Bearing Ore Is Mined, Wallace T. Roberts. Min. & Sci. Press, vol. 118, no. 1, Jan. 4, 1919, p. 30, 3 figs.; Mine & Quarry, vol. 11, no. 1, Nov. 1918, pp. 1106-1110, 8 figs. Nov.; Prospecting carnotite areas in Colorado; Jan. 4; Methods of prospecting followed by Colorado companies.

Radium: Its Properties and Occurrence in Nature—II, Richard B. Moore. Metal Rec. & Electroplater, vol. 4, no. 11, Dec. 1918, pp. 391-393. History of metal; location of principal ores and method of working each; present uses and future possibilities; mesothorium as substitute.

New Minerals

Review of New-Mineral Species (Revue des espèces minérales nouvelles), P. Gaubert. Bulletin de la Société Française de Minéralogie, vol. 41, nos. 4-5-6, Apr-June 1918, pp. 93-96. Occurrences of crestmoreite, riversideite, katoptrite, ektropite, and flokite, pp. 117-130. Occurrences of crandallite, leifite, griffithite, mullanite, tetarkaite, didymolite, angaralite, arseno-bismite, arseno-ferrite, heliodore, creedite, sulphated cancrinite, cebollite, pintadoite, uvanite, hogbomite, minasragrite, aurobismuthinite, stibiobismuthinite.

Uncommon Ores

Uncommon Ores and Metals, H. C. Meyer. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 124-125. Uses and demand of palladium, selenium, strontium ore, thorium ore, titanium, uranium and zirconium.

TIN

Conservation

Symposium on the Conservation of Tin. Metal Rec. & Electroplater, vol. 4, no. 11, Dec. 1918, pp. 387-390 and 403. Methods by which tin can be saved and its use reduced; tin alloys; bearing metals, soldiers, babbitts, bronzes and their substitutes.

VARIA

Laws, Mining

Mining Law and Economics. Minerals, Mines and Quarries, David Bowen. Quarry, vol. 24, no. 263, Jan. 1919, pp. 5-7. Review of authoritative definitions of mineral, ore, mine and quarry with reference to English and continental European legal decisions establishing scope of signification.

Minerals, International Control

International Control of Minerals, C. K. Leith. Department of Interior, U. S. Geol. Survey, Mineral Resources of U. S., 1917—part 1, Dec. 31, 1918, pp. 7a-16a. Movement of minerals under pre-war conditions of international trade; possibility of post-war international control; specific plans of international control of minerals; position of U. S.; general conclusions from standpoint of U. S.

Production, U. S. for 40 Years

40 Years of Domestic Metal Production. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp. 180-181, 2 figs. Steady increases shown throughout last 50 years; efforts being made to increase production.

Metallurgy

ALUMINUM

Alloys

Aluminum and Its Light Alloys—IV, Paul D. Merica. Metal Rec. & Electroplater, vol. 4, no. 11, Dec. 1918, pp. 384-386. Importances of these light-weight metals for motor and aircraft construction; metallography of commercial aluminum; chemical and physical properties at high and low temperatures; tensile properties of zinc-aluminum alloys. (To be continued.)

Analysis

The Analysis of Aluminum Alloys and Metallic Aluminum, J. J. Fox, E. W. Skelton and F. R. Ennos, Jl. Soc. Chem. Indus., vol. 37, no. 24, Dec. 31, 1918, pp. 328T-333T. Methods writers have found suitable for general work. Reagents used are a 10 per cent solution of pure sodium hydroxide, and nitrosulphuric acid made by mixing 300 cc of concentrated sulphuric acid with 300 cc of water, cooling, and adding 200 cc of pure nitric acid.

Analysis of Hard Aluminum Alloys (Analyse des alliages durs d'aluminium), A. Travers. Chimie & Industrie, vol. 1, no. 7, Dec. 1, 1918, pp. 708-711. Methods in use at Creusot works for quantitative analysis of zinc, aluminum, magnesium and copper in light alloys.

Dust, Inflammability of

The Inflammability of Aluminum Dust, Alan Leighton. Department of Interior, Bur. of Mines, Tech. Paper 152, 15 pp. Review of available literature; experimental work; properties affecting explosibility; precautions to be observed.

Metallography

The Metallography of Aluminum, Robert J. Anderson. Jl. Franklin Inst., vol. 187, no. 1, Jan. 1919, pp. 1-47, 65 figs. Discussion of amorphous theory and plastic deformation; observations on grain-growth phenomena; micrographs of various forms of aluminum, cast, worked, and annealed; annealing and recrystallization of aluminum which has undergone plastic deformation; experimental investigation of exaggerated grain growth in aluminum; process of polishing and etching aluminum microsections preparatory to microscopic examination.

BLAST FURNACES

Car Dumper

Movable Car Dumper with Rotary Cradle, A. F. Case. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 60-61, 2 figs. Machine located near storage yard for handling ore and limestone at blast-furnace plant. Said to be capable of unloading 30 to 35 cars an hour.

Gas Operation

Blast Furnace Plant Blows in First Stack. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 50-56, 6 figs. Installation of combined blast-furnace gas and chain-grate stokers firing on heavy mill loads. Gas cleaning designed to keep both stoves and washer clean and in operation throughout entire blast.

Potash

Potash Content of Blast Furnace Charges, N. H. Gellert. Iron Age, vol. 103, no. 6, Feb. 6, 1919, pp. 355-356. Alabama iron ores and foreign manganese ores contain the most; potash in the burden of American furnaces.

Slag

Widening Demand for Blast Furnace Slag, Clarence E. Wright. Iron Age, vol. 103, no. 4, Jan. 23, 1919, pp. 241-243, 5 figs. Uses to which it has been put; a possible \$20,000,000 income to industry.

Thickener

Dorr Thickener in Blast-Furnace Field. Iron Age, vol. 103, no. 2, Jan. 9, 1919, pp. 112-115, 3 figs. Used in clarification of washer discharge water it eliminates troublesome problems and yields valuable product; simplicity of operation.

COPPER

Boron Deoxidizer

The Boronic Deoxiding of Copper, James Scott. Foundry Trade Jl., vol. 20, no. 203, Nov. 1918, pp. 598-599, 3 figs. Experimental research of procedure followed by boronic compounds when acting on copper and its alloys.

Bronze Heat Treatment

Effect of Heat Treatment on Bronze, F. F. Hansen and O. A. Knight. Iron Age, vol. 103, no. 6, Feb. 6, 1919, pp. 347-349, 12 figs. Characteristics disclosed by Brinell hardness tests and photomicrographs; quenching and drawing give greater hardness than quenching alone.

Bronze Inclusions

Nonmetallic Inclusions in Bronze and Brass, G. F. Comstock. Foundry, vol. 47, no. 318, Feb. 1919, pp. 79-83, 21 figs. From a paper presented at the October meeting of the Institute of Metals Division of the Am. Inst. of Min. Engrs.

Heap Leaching

Metallurgy of Copper, Arthur L. Walker. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 90-92. Heap-leaching experiments being conducted in southwestern copper centers; Anaconda fume-dust collector.

FERROALLOYS

Production

Ferroalloys Production Stimulated. Iron Trade Rev., vol. 64, no. 1, Jan. 2, 1919, pp. 118 and 120. Imports and domestic production of manganese alloys; imports of manganese ore; stimulation in production of spiegeleisen.

1918

Ferro-Alloys in 1918, Robert J. Anderson. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 83-86. Technical advances in metallurgical processes.

FLOTATION

Flotation Machines

The Flotation Process, A. W. Allen. Eng. & Min. Jl., vol. 107, no. 2, Jan. 11, 1919, pp. 97-100. New flotation machines; progress in selective flotation; development of Galena flotation; separate treatment of colloids.

IRON AND STEEL

Blast Furnaces

See preceding column.

Case-Hardening

Ancient and Modern Carbonizing Methods, Theodore G. Selleck. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 7-12, 4 figs. Discusses use of compounds for case-hardening and describes improved methods. Uniform results secured by preheating.

Chrome Steel

Physical Qualities of High Chrome Steel, L. R. Seidell and G. J. Horvitz. Iron Age, vol. 103, no. 5, Jan. 30, 1919, pp. 291-294, 4 figs. Relation between hardness and double carbides in solution; critical temperatures; maximum tensile strength and ductility.

Density

Specific Density of Steel, H. E. Roerr. Iron Age, vol. 103, no. 3, Jan. 16, 1919, p. 184, 1 fig. Extent to which forging compresses or consolidates metal. From paper for Feb. meeting of Am. Inst. of Min. Engrs., New York.

Furnaces

Pulverized Coal for Metallurgical Furnaces, Charles E. Longenecker. Iron Age, vol. 103, no. 6, Feb. 6, 1919, pp. 351-352, 1 fig. Greater efficiency claimed for furnaces of correct design; continuous service more certain; average combustion figures for different furnace types.

Germany

The Future of the German Iron Industry, H. Müngesheimer. Cassier's Eng. Monthly, vol. 54, no. 6, Dec. 1918, pp. 340-341. Opinion of General Director of Gelsenkirchen Steel and Iron Works.

Heat Treatment and Grain Size

Grain Limits in Heat-Treated Alloy Steels, R. S. Archer. Iron Age, vol. 103, no. 6, Feb. 6, 1919, pp. 366-367, 12 figs. New etching process which defines the crystals, boundaries and assists in detecting faulty heat treatment. From paper for February meeting of American Institute of Mining Engineers, New York.

High-Speed Steel

Durability of High Speed Steels, R. Poliakoff. Iron Age, vol. 103, no. 5, Jan. 30, 1919, pp. 295-296, 2 figs. Russian cutting tests with nine brands; chemical composition and requirements; results compared with Taylor's conclusions.

Hot Deformation of Steel

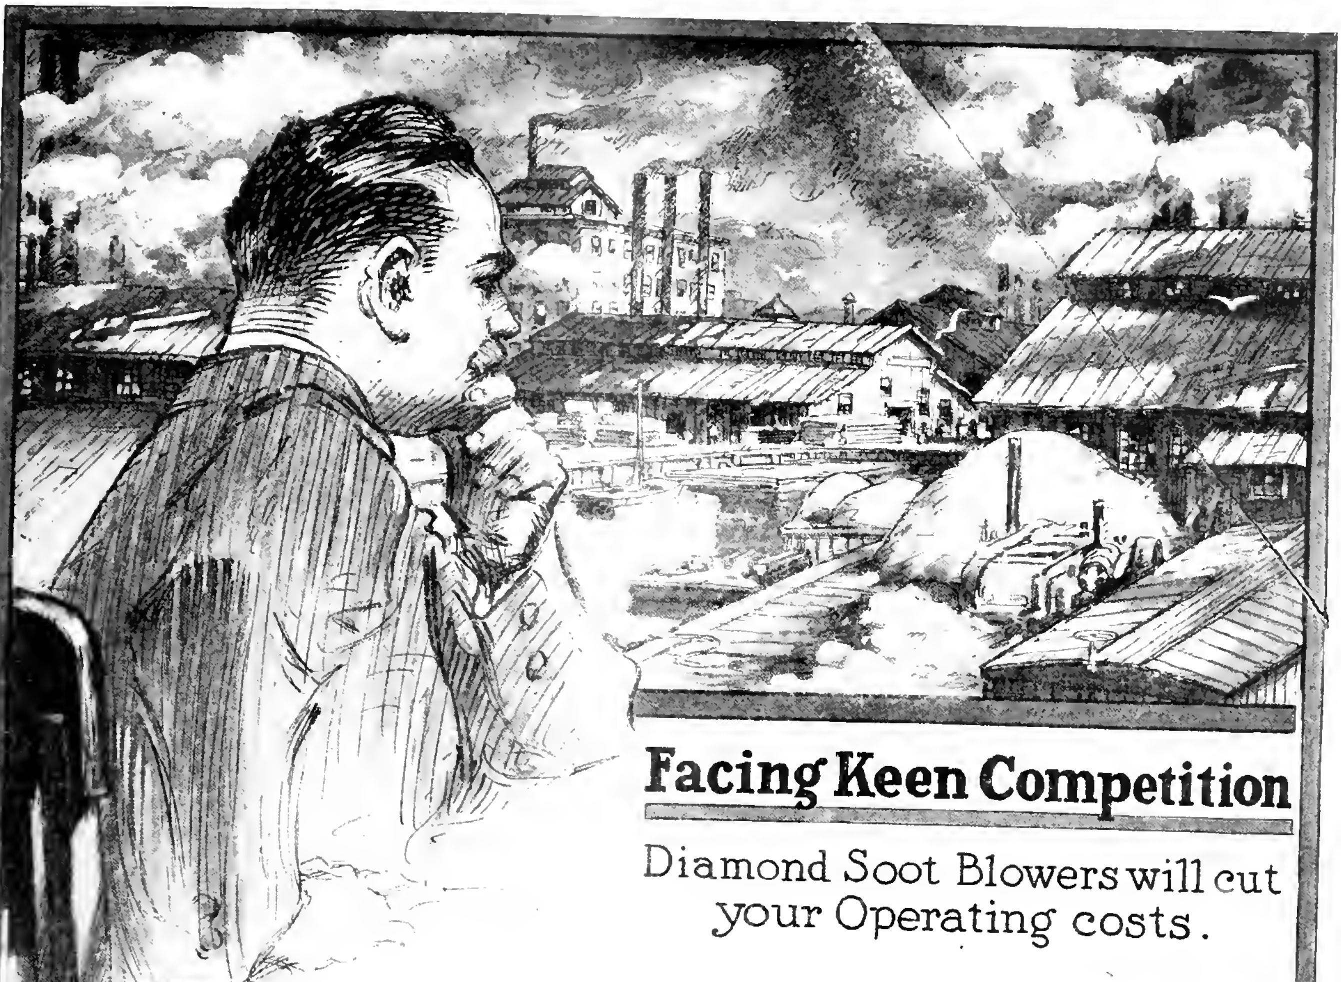
Influence of Hot Deformation on Steel, George Charpy. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 482-488, 3 figs. Technical discussion on effect of rolling and forging on structure of steels; data concerning changes on exterior and interior of forgings. From paper presented before Iron & Steel Inst.

Literature for 1918

Review of Iron and Steel Literature for 1918, E. H. McClelland. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 73-75. Classified list of important books, serials and trade publications.

Molybdenum Steel

Molybdenum Steel Versus Gun Erosion, Masatosi Okôchi, Massaichi Majima and Naoshi Sato. Jl. College of Eng., Tokyo Imperial Univ., vol. 9, no. 5, Oct. 15, 1918, pp. 153-195, 50 figs. Experimental determination of modulus of elasticity, modulus of rigidity, Brinell hardness number, thermal dilatation, thermal conductivity and magnetization at high temperatures of specimens of gun steel, nickel steel, nickel-molybdenum steel and tungsten steel.



Phosphorus

Effect of Phosphorous in Soft Acid and Basic Open Hearth Steels, J. S. Unger. Proc. Steel Treating Research Soc., vol. 2, no. 1, 1919, pp. 11-23, 11 figs. None of the steels used in experiments showed brittleness under cold working, due to phosphorus. Results of various mechanical tests, cold bending of rivets under hammer, upsetting in making barrels, automobile parts and cream separator large-headed nails or rivets, or fabrication of bowls, indicated increase of hardness with increase of phosphorus.

Phosphorus in Malleable Cast Iron, J. H. Teng. Iron & Steel Can., vol. 1, no. 11, Dec. 1918, pp. 445-453, 7 figs. Effects of proportions of phosphorus varying from 0.05 to 0.5 per cent on mechanical properties of malleable cast iron. Writer concludes that ill effects become marked at 0.2 per cent. Paper presented before Iron & Steel Inst., Sept. 1918.

Refractories

See Refractories, under Mechanical Engineering.

Rolling and Grain Size

The Grain Size in Steel as Influenced by Rolling, W.G. Dauncey. Monthly Bul. Can. Min. Inst., no. 82, Feb. 1919, pp. 164-166, 4 figs. Photomicrographs of portion of rolled basic steel bar

Rolling Mills

See Mechanical Processes (Plate Mills), under Mechanical Engineering.

Steel Failures

The Cause and Mechanism of Steel Failures, Z. W. Zimmerschied. Proc. Steel Treating Research Soc., vol. 2, no. 1, 1919, pp. 24-25 and 28-29 Analysis of reasons for usual failures of automobile parts.

Steel Industry in 1918

General Review of Steel Industry for 1918, B. E. V. Luty. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 62-65. Quantity and character of output; alignment of belligerents; labor and wages; necessity of labor-saving machinery.

Tests

Tension, Impact and Repeated Impact Tests of Mild and Hard Steels, Tsuruzo Matsumura. Memoirs College of Eng., Kyoto Imperial Univ., vol. 2, no. 2, July 1918, pp. 63-69, 16 figs. Experiments on six flat bars varying in percentage of carbon from 0.102 to 0.65, to detect cause of unexplained fractures.

NON-FERROUS ALLOYS

Stellite

Stellite—Its Manufacture and Uses. Can. Mfr., vol. 39, no. 1, Jan. 1919, pp. 77-78, 2 figs. How it is manufactured at Deloro, Ont.

Welding

Behavior of Non-Ferrous Metals Under the Oxy-Acetylene Torch—II, J. F. Springer. Metal Rec. & Electroplater, vol. 4, no. 11, Dec. 1918, pp. 381-383. How copper alloys are welded; process when working with magnesium, nickel, silver, gold, lead, tin and zinc.

Zinc Alloys

Zinc Alloys Instead of Copper Alloys. Iron Age, vol. 103, no. 3, Jan. 16, 1919, p. 175. French experiments on certain combinations of zinc, aluminum and copper as cast, rolled or drawn under a press.

See also ELECTRICAL ENGINEERING, Electrodeposition.

OCCLUDED GASES

Reactions

Notes on the Occlusion of Gases in Metals, Alfred W. Porter. Chem. Engr., vol. 26, no. 13, Dec. 1918, pp. 499-500 and 509, 1 fig. Phases of reactions between gases and metals as determined by various experimenters.

Aeronautics

AEROPLANE PARTS

Starters

The Bijur Airplane Engine Starter. Aviation, vol. 6, no. 1, Feb. 1, 1919, pp. 33-34, 3 figs. Characteristics of starter designed with minimum weight and low current consumption combined with maximum of cranking power to break away a stiff engine. It is used particularly on seaplanes.

Bijur Starters for Seaplanes and Blimps. Automotive Industries, vol. 40, no. 2, Jan. 9, 1919, p. 51, 3 figs. Fitted to Liberty engines at propeller end and crank engine through double-reduction gear with Bijur automatic screw shift.

AEROSTATICS

Airship Possibilities

The Case for the Airship, W. Lockwood Marsh. Aviation, vol. 5, no. 11, Jan. 1, 1919, pp. 697-699. Salient features and adaptabilities of lighter-than-air and of heavier-than-air craft.

Future of the Helium Airship, Ladislas d'Orcy. Aviation, vol. 5, no. 11, Jan. 1, 1919, pp. 695-697, 2 figs. How helium was produced; military aspects of discovery.

See also INDUSTRIAL TECHNOLOGY, Helium.

AIRCRAFT PRODUCTION

Naval Aircraft Factory

The Naval Aircraft Factory. Aviation, vol. 6, no. 1, Feb. 1, 1919, pp. 28-30, 7 figs. Site, dimensions and internal organization; naval flying boats.

The Naval Aircraft Factory. Mech. Eng., vol. 41, no. 2, Feb. 1919, pp. 142-146, 14 figs. Organization of staff and working force; employment of women; operation of the various departments; features of standardized seaplane manufacture at the plant.

APPLICATIONS

American View

The Opportunity of Aviation, William B. Stout. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 39-41 and (discussion) pp. 41-42. Difficulties to be overcome; engine development in the war; problem of landing; cost of production.

British View

Lord Weir on the Future of Flying. Flight, vol. 11, no. 1, Jan. 2, 1919, pp. 16017. Measures upon which development of operational side of air transport depends and part the State is to play in this development.

Commercial Aeronautics

Problems of Commercial Aeronautics, G. Lepere. Aviation, vol. 5, no. 11, Jan. 1, 1919, p. 694. Commercial uses of existing military planes; present possibilities of design.

Commercial Transport by Airplane. Aviation, vol. 6, no. 1, Feb. 1, 1919, pp. 31-32; Aeronautics, vol. 15, nos. 270 and 271, Dec. 18 and 25, 1918, pp. 577-592 and 608-638; Flight, vol. 10, nos. 50, 51, 52 and vol. 11, no. 1, Dec. 12, 19, 26, 1918 and Jan. 2, 1919, pp. 1413-1418, 1413-1445, 1465-1470, and 22-27 Report of special committee on law and policy; interim report of special committee on technical and practical questions of aerial transport; memorandum on experimental air service; business questions relating to aircraft industry and aerial services; labor; research and export education.

DYNAMICS

Aerofoil Sections

Selecting Aerofoil Sections for Speed Range, V. E. Clark. Aviation, vol. 6, no. 1, Feb. 1, 1919, pp. 20-22, 2 figs. Charts for selecting approximately best aerofoil section for speed range and to estimate speed performance to be expected in a given airplane.

Calculation of Performance

Performance of Aeroplanes, W. L. Cowley. Flight, vol. 11, no. 1, Jan. 2, 1919, pp. 13-15, 7 figs. Mathematical relations between horsepower, rate of climb and turning circle; conditions under which circular flight may be extended with greatest rapidity.

Flattening-Out of Aeroplanes

Flattening-Out of Aeroplanes After Steep Glides, Genjiro Hamabe. Memoirs College of Eng., Kyoto Imperial Univ., vol. 2, no. 1, June 1918, pp. 7-52, 8 figs. Derivation of general equations of rigid dynamics with center of gravity of aeroplane as origin; discussion of symmetric motion of aeroplane; problem of recovery from a steep dive at high speed treated by method of approximate calculation; application of approximate calculation to various cases of sharp flattening out of a military Curtiss JN2 tractor.

PLANES

Christmas

The Christmas Strutless Biplane. Aerial Age, vol. 8, no. 19, Jan. 20, 1919, pp. 948-949, 8 figs. Struts, cables and wires are entirely eliminated in machine reported to make 170 miles an hour with a 6-cylinder Liberty motor.

German Planes

The Trend of German Aeroplane Design. Engineer, vol. 127, no. 3289, Jan. 10, 1919, pp. 25-26. From a report issued by the Aircraft Production (Technical Department), Ministry of Munitions.

Halberstadt

Report on the Halberstadt Two-Seater Type C. L. IV. Aeronautics, vol. 15, no. 269, Dec. 11, 1918, pp. 550-552, 12 figs; Flight, vol. 10, no. 50, Dec. 12, 1918, pp. 1404-1407, 12 figs. Biplane equipped with 180-hp. Mercedes engine; carries one fixed and one movable gun. Similar to C. L. II type. Issued by Technical Department, Aircraft Production, Ministry of Munitions.

Loening

The Loening Two-Seater Fighting Monoplane. Aviation, vol. 5, no. 11, Jan. 1, 1919, p. 689, 1 fig. Brief description of simplified type of fighting airplane designed to facilitate production.

L. V. G.

The L. V. G. Two-Seater Biplanes. Engineer, vol. 126, nos. 3284 and 3286, Dec. 6 and 20, 1918, pp. 483-486 and 525-527, 26 figs. and 17 figs.; Flight, vol. 10, nos. 51 and 52, Dec. 19 and 26, 1918, pp. 1426-1431 and 1457-1461, 20 figs.; Aeronautics, vol. 15, no. 267, Nov. 27, 1918, pp. 496-503, 48 figs. Engineer, Dec. 6; Description and illustrations of details of construction; Flight, Dec. 19; C. V. and C. VI. types; Dec. 26; Wing construction, struts, ailerons, undercarriage controls, engine mounting, oil system, accessories. Issued by technical Dept., Aircraft Production, Ministry of Munition; Aeronautics, Nov. 27, C. V. and V. I. types. Report of Technical Department of Air Ministry.

Martin

The Martin Twin-Engined Bomber, Donald W. Douglas. Aviation, vol. 5, no. 11, Jan. 1, 1919, pp. 677-680, 9 figs. Machine built to fulfill requirements of night bomber, day bomber, long-distance photography, and gun machine.

Pfalz

Report on the Pfalz (D xii) Single-Seater Fighter. Aeronautics, vol. 15, no. 269, Dec. 11, 1918, pp 544-549, 19 figs. Biplane equipped with 180-hp. Mercedes engine; carries two Spandau fixed guns. By technical Department, Aircraft Production, Ministry of Munitions.

Standard C-1

The Standard C-1 Single Seater. Aerial Age, vol. 8, no. 20, Jan. 27, 1919, pp. 985-987, 6 figs. Characteristics of Standard Aero Corporation biplane designed as secondary training machine.

ENGINES

Altitudes

Performance of Aeronautic Engines at High Altitudes, H. C. Dickinson. Aeronautics, vol. 15, no. 269, Dec. 11, 1918, pp. 542-543, 3 figs. Describes a laboratory building where it is contemplated to study engine performance in general, including carburation, under conditions corresponding to highest altitudes reached by aviators.

Carburation

Carbureting Conditions Characteristic of Aircraft Engines. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 9-12, 9 figs. Tests to determine changes in engine performance with changes in atmospheric temperature and pressure at various levels above earth's surface, with special reference to variables affecting functioning of carburetor and changes in performance resulting from variables in carburetor itself. From Bur. of Standards report no. 10 on aeronautic power plants.

Curtiss

The Curtiss Model K 12 Cylinder Airplane Engine. Aviation, vol. 5, no. 11, Jan. 1, 1919, pp. 685-689, 7 figs. Principal features. Engine is of fixed cylinder type and consists of 12 cylinders in two groups of six each, with included angle of 60 deg.

Dusenberg

The Dusenberg Model H 850-Hp. Motor, G. Douglas Wardrop. Aerial Age, vol. 8, no. 20, Jan. 27, 1919, pp. 991-995, 12 figs. General dimensions and particulars. Motor is of 16-cylinder V type with cylinders at an angle of 45 deg.; weight of power plant with gear drive is 1575 lb.

Hispano-Suiza

The Model H, 300-Hp. Hispano-Suiza Engine, Aviation, vol. 6, no. 1, Feb. 1, 1919, pp. 23-26, 4 figs. Points in which model H differs from other Hispano-Suiza engines, and particularly with regard to lubrication.

Liberty Engine

Ignition on Liberty Engine. Motor Age, vol. 35, no. 2, Jan. 9, 1919, pp. 20-21 and 39, 10 figs. Wiring diagram; arrangement of three arms of circuit breaker; diagram of firing order. Generator-battery type; special Delco system is used.

Miller

The Miller 125-Hp. Aircraft Engine. Aviation, vol. 6, no. 1, Feb. 1, 1919, pp. 30-31, 2 figs. Features and dimensions of this four-cylinder engine.

Radio Cylinder

Fixed Radial Cylinder Engines, John W. Smith. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 24-26, 5 figs. Weight of power plant; reliability, durability and balancing; fuel and oil consumption; streamline mounting; cooling. Radial engine is considered as having more advantages than V type.

Specification of Engines

Complete Technical Specifications of Important American and Foreign Airplane Engines. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, Supplement, chart between pp. 134-135. Details of 37 different types as compiled by Technical Section, Division of Military Aeronautics.

MATERIALS OF CONSTRUCTION

Plywood

Plywood in Aeroplane Construction, Henry Harrison Suplee. Aerial Age, vol. 8, no. 19, Jan. 20, 1919, pp. 945-947 and 961, 7 figs. Design and construction of plywood monocoque fuselages, plywood wing ribs and fuselage taps.

MECHANICS

Stress Determination

Stress Optical Experiments, A. R. Low. Flight, vol. 10, nos. 50 and 51, Dec. 12 and 19, 1918, pp. 1409-1410 and 1435-1439, 20 figs. Dec. 12: Examples of optical observations. Dec. 19: Deflection curves for top spar calculated and observed for total loads of 10, 20, 30, 35 and 40 lb.; principle of dynamical similarity applied to deformable elastic structures. (Concluded.)

Struts

Design of Aeroplane Struts, W. H. Barling and H. A. Webb. Aeronautics, vol. 15, nos. 268 and 269, Dec. 4 and 11, 1918, pp. 521-525, and 538-541, 9 figs. Dec. 4: Analytical determination of shape which will cause strut, when endload rises and it deflects, to be subjected to the same maximum stress at every section; Dec. 11: Mathematical theory and formulae, numerical examples, crinkling stress of steel tubes. Paper read before Roy. Aeronautical Soc.

An Approximate Graphical Treatment of Some Strut Problems, John Case. Engineering, vol. 106, no. 2764, Dec. 20, 1918, pp. 699-670, 7 figs. Mathematical article discussing crippling load of a pin-jointed strut of verying section; deflection of a strut with lateral load; deflection of a strut subjected to lateral load and terminal couples; continuous beams with end load; proofs of formulæ.

Wing-Structure Calculation

Incidence Wires in the Strength Calculations of Wing Structures, John Case. Aeronautics, vol. 15, nos. 268, 270 and 271, Dec. 4, 18 and 25, 1918, pp. 516-517, 566-570 and 602-607, 25 figs. Dec. 4: Ordinary processes of statics and principle of least work, as methods of computing thrust in members of frame. Physical aspect of difference between the two methods; Dec. 18: Formulæ for estimating loads in spars, struts, etc., and numerical examples of the methods of using these formulæ; Dec. 25: derivation of formulæ.

MILITARY AIRCRAFT

British Planes

British Airplanes and Seaplanes. Automotive Industries, vol. 40, no. 3, Jan. 16, 1919, pp 142-143. Principal types of engines and planes in use in the Royal Naval Air Service and in the Army.

U. S. Le Pere

The Le Père Fighter. Aerial Age, vol. 8, no. 18, Jan. 13, 1919, pp. 904-905, 5 figs. General dimensions, weights and performances of reconnaissance plane fitted with 400-hp Liberty engine.

U. S. Planes

Record of Performance of American Planes. Automotive Industries, vol 40, no. 3, Jan. 16, 1919, p. 103. Table illustrating types and principal features of airplanes built by U. S. Government since June 1917.

MODELS

Model Construction

Model Aeroplane Building as a Step to Aeronautical Engineering. Aerial Age, vol. 8, nos. 18, 19 and 20, Jan. 13, 20 and 27, 1919, pp. 913, 957 and 1001, 11 figs. Jan. 13: Details of wings; Jan. 20: Making tail surfaces, fin and rudder; Jan. 27: Details of stabilizer, elevators, fin and rudder for Ford motored airplane.

Model Aeroplanes—XIX, F. J. Camm. Aeronautics, vol. 15, no. 268, Dec. 4, 1918, p. 529, 6 figs. Notes on driving mechanism.

PROPELLERS

Charts

Nomographic Charts for the Aerial Propeller, S. E. Slocum. Aerial Age, vol. 8, no. 20, Jan. 27, 1919, pp. 988-990, 4 figs. Power, thrust, torque and efficiency charts representing formulæ derived from experimental data. Formulæ were discussed in Aerial Age, Aug. 26 and Nov. 18, 1918.

Marine Engineering

AUXILIARY EQUIPMENT

Condensers

Auxiliary Machinery on British Standard Ships. Shipbuilding and Shipping Rec., vol. 12, no. 25, Dec. 19, 1918, pp. 595-596, 5 figs. General arrangement of auxiliary machinery for A and B types; details of auxiliary condenser incorporated in main engine structure on marine engines.

Propellers

Chart for Diameters of 3-Bladed Propellers. Motor Boat, vol. 16, no. 1, Jan. 10, 1919, p. 12, 1 fig. To determine diameter of propeller from desired revolutions and hp. delivered.

Screw Propellers, C. W. Dyson. Jl. Am. Soc. Naval Engrs., vol. 30, no. 4, Nov. 1918, pp. 753-805, 4 figs. Theoretical discussion covering thrust deduction and wake gain; slip block coefficients; wing screws; correction of slip block coefficient for variation of midship section coefficient from standard; mean relative tip clearance of propellers; resistance of hull appendages; basic conditions for analysis and design of screw propellers; general formulæ for power correction for "cavitation" and "dispersal of thrust column"; standard forms of projected area ratio; standard forms of blade sections; problems in propeller design.

Valves and Fittings

Marine Practice in Valves and Fittings, A. G. Christie. Mech. Eng., vol. 41, no. 2, Feb. 1919, pp. 135-136. Suggests that certain features of central-station practice be extended to marine practice.

SALVAGE

Salvaging Device

Making the Sea Give Up Its Wealth. Am. Marine Engr., vol. 14, no. 1, Jan. 1919, pp. 12-14, 1 fig. Patented salvaging device consisting of dual system of non-capsizing pontoons to serve as lighters for salvage and quarters and workshops for wrecking crews as well as for raising vessels on an even keel.

S.S. St. Paul

The Salvage of the St. Paul. Engineer, vol. 126, no. 3284, Dec. 6, 1918, pp. 480-483, 7 figs. Account of raising of liner which sank at her pier in New York harbor.

SHIPS

Camouflage

Principles Underlying Ship Camouflage, Alon Bement. Int. Mar. Eng., vol. 24, no. 2, Feb. 1919, pp. 90-93, 9 figs. Complementary colors to produce low visibility; dazzle system of ambiguous perspective to disguise ship's course; special color effects.

Castings

Castings Used in Ship Construction, Ben Shaw and James Edgar. Foundry Trade Jl., vol. 20, no. 203, Nov. 1918, pp. 579-584, 26 figs. Methods adopted in making pattern for and casting rudder; general considerations on large and small castings.

Concrete Vessels

Reinforced-Concrete Steamer "Armistice." Engineering, vol. 107, no. 2767, Jan. 10, 1919, pp. 46-48, 8 figs. Illustrations with general description of a 205-ft. concrete steamer constructed by the Ferro-Concrete Ship Construction Company, Limited, Barrow-in-Furness.

Concrete Ships. Times Eng. Supp., no. 530, Dec. 1918, pp. 252-253. Program at Lancashire yards; equipment of yards.

New Type of Reinforced Concrete Boat. Concrete Age, vol. 29, no. 3, Dec. 1918, pp. 24-25. System followed at Aberthaw yard for building 500-ton lighters.

Structural Details of Concrete Ships, W. Noble Twelvetrees. Nautical Gaz., vol. 95, no. 2, Jan. 11, 1919, pp. 24-25. Systems of concrete shipbuilding followed in British shipyards and advantages claimed by advocates of each system. From the Shipbuilder.

The Waller System of Reinforced Concrete Ship Construction, W. Noble Twelvetrees. Engineering, vol. -06, no. 2760, Nov. 22, 1918, pp. 580-583, 16 figs. Description of system introducing precast concrete slabs into construction.

Detail Drawing Methods

Detail Drawing Method Used for 8800-Ton Steel Ships. Eng. News-Rec., vol. 82, no. 4, Jan. 23, 1919, pp. 188-190, 3 figs. Adapted successfully to old-style ships of fully curved shape; permits checking pieces before they leave shop.

Electrical Installation Work

Cutting Time on Installation Work. Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 25-26. Systematic planning of electrical installation work as carried out in large shipyard.

Electric Propulsion

The Ljungstroöm Turbo-Electric System of Ship Propulsion. Jl. Am. Soc. Naval Engrs., vol. 30, no. 4, Nov. 1918, pp. 813-834, 60 figs. Ljungström turbine consists of two disks carrying intermeshing rings of reaction blading; each disk is direct-coupled to a generator. Turbine, equipment, auxiliaries and mountings are treated at length. From Engineering.

Electric Propulsion on the New Mexico, Wingrove Bathon. Elec. World, vol. 73, no. 1, Jan. 4, 1919, pp. 7-10, 1 fig. Interview with Rear-Admiral Griffin of U. S. N. New system of driving ships adopted as national policy; Great Britain and France probably will follow American lead.

Fabricated Ship

The Fabricated Ship in America. Engineer, vol. 126, no. 3286, Dec. 20, 1918, pp. 523-524, 12 figs. Description and discussion of the "fabricated" ship.

Ferry Steamers

Train Ferries to France. Times Eng. Supp., no. 530, Dec. 1918, p. 251, 3 figs. Engineering features of ferry steamers and of bridges for loading and unloading them.

Ford Chasers

Ford Methods in Ship Manufacture—II, Fred E. Rogers. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 119-124, 12 figs. Layout, equipment and tools of shop where 200 tons of interchangeable steel parts for the Eagles are produced in a working day. (To be continued.)

The Building of American Submarine Chasers. Engineering, vol. 106, no. 2761, Nov. 29, 1918, pp. 608-609, 3 figs. Account of construction of Ford "Eagles."

Groton Shipyard

Groton Shipyard Built on Sloping Limestone Ledge. Eng. News-Rec., vol. 82, no. 3, Jan. 16, 1919, pp. 135-138, 6 figs. Fabricating and storage yards level with rails on concrete craneways and 22 ft. above concrete shipways set into rock.

Hog Island Ship

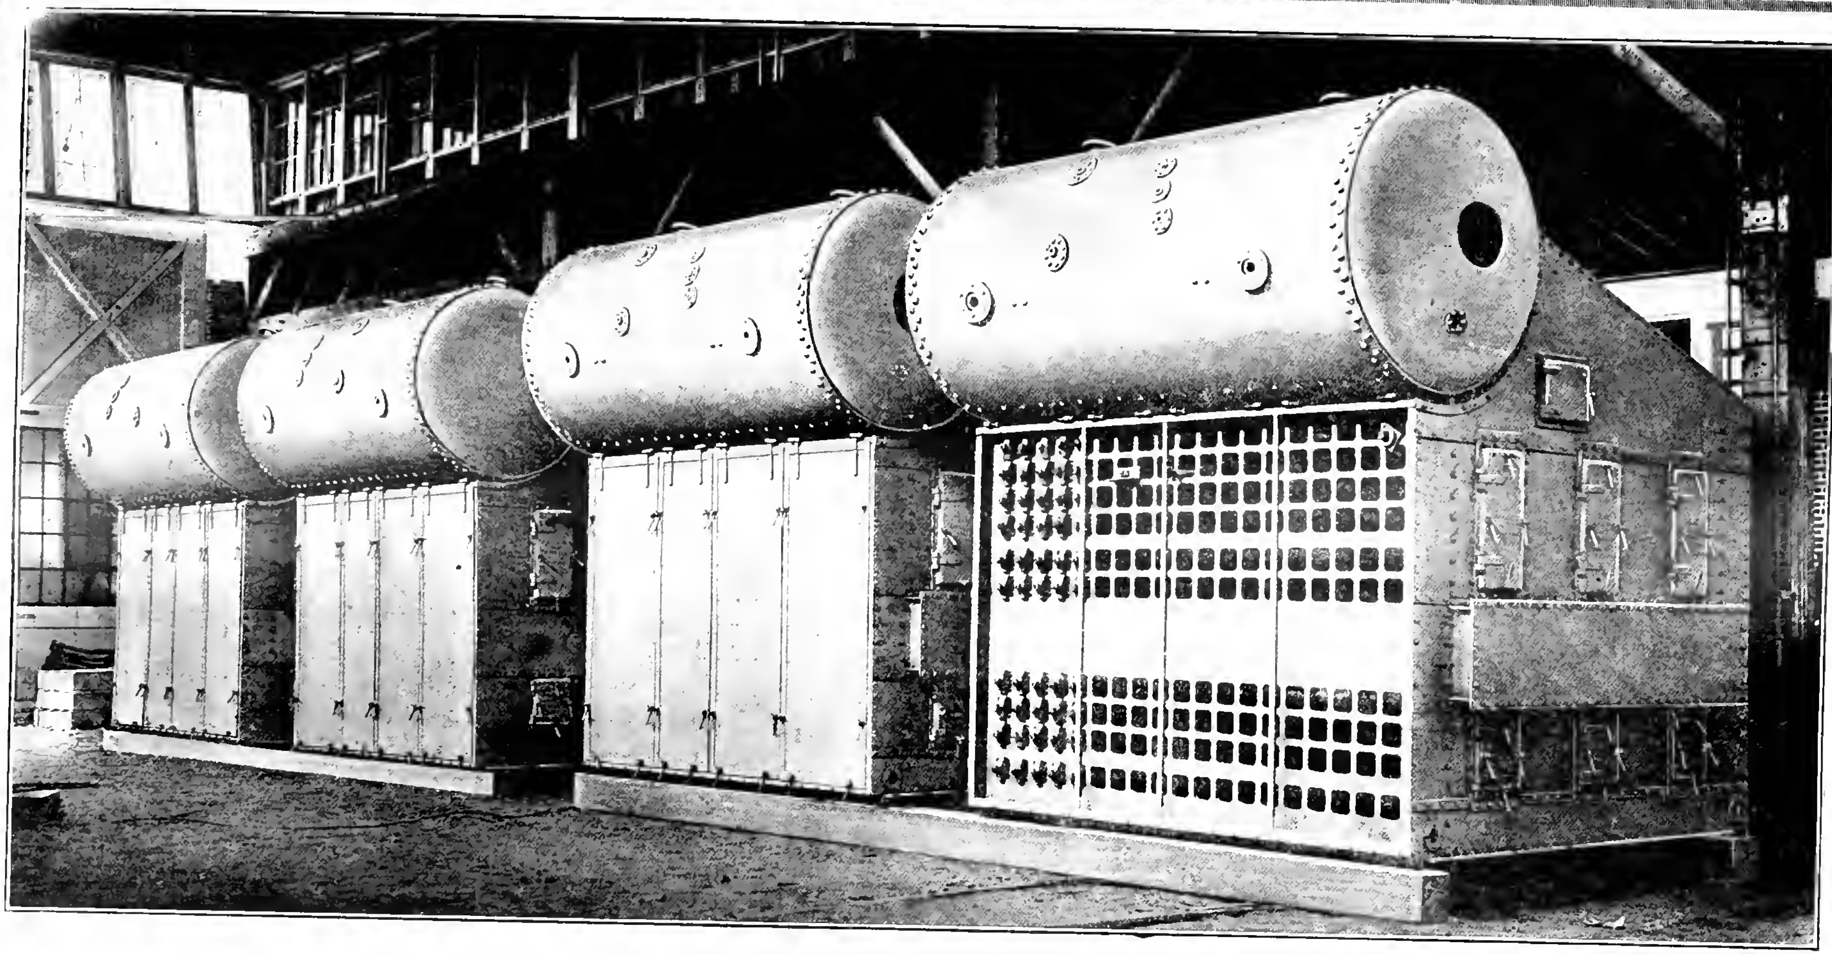
Plans for Hog Island Steel Cargo Ship. Int. Mar. Eng., vol. 24, no. 2, Feb. 1919, pp. 71-74, 3 figs. Design and construction of single-screw vessel of 7500 tons deadweight type; cargo space 380,000 cu. ft.

Launching

Notes on Launching, William Gatewood. Engineering, vol. 106, no. 2764, Dec. 20, 1918, pp. 710-711, 7 figs.; Int. Mar. Eng., vol. 24, no. 2, Feb. 1919, pp. 83-87, 7 figs. Paper before Society of Naval Architects and Marine Engineers, Philadelphia, Nov. 1918.

Refrigerator Ships

The Refrigerator Ship "Belle-Isle" (Le navire frigorifique "Belle-Isle"), Emile Gouault. Génie Civil, vol. 73, no. 26, Dec. 28, 1918, pp. 501-504, 7 figs. Conformation and plans. Ship is three-decked and of awning-deck type, with capacity of 12,000 beeves.



Turbine Propulsion

Italian Geared Turbine Cargo Steamer. Int. Mar. Eng., vol. 24, no. 2, Feb. 1919, pp. 94, 2 figs. Brief description with plan of ship. Built by N. Odero & Company, at Sestri Ponenti, and fitted with Tosi geared turbine propelling and auxiliary machinery.

Progress in Turbine Ship Propulsion, Francis Hodgkinson. Engineering, vol. 107, no. 2767, Jan. 10, 1919, pp. 42-45, 9 figs. Report, slightly abbreviated, read before the Society of Naval Architects and Marine Engineers, Philadelphia, Nov. 1918.

Progress in Turbine Ship Propulsion, Francis Hodgkinson. Shipping, vol. 5, no. 13, Dec. 28, 1918, pp. 15-16, 1 fig. Auxiliaries used and practice followed. Abstract of paper before Soc. Naval Architects and Marine Engrs.

Ventilating and Heating

Ventilating and Heating from the Marine Point of View, Chas. F. Gross. Jl. Am. Soc. Naval Engrs., vol. 30, no. 4, Nov. 1918, pp. 728-736. Systems followed in merchant ships; design and installation of ventilators; allowance of square feet of radiator surface by leading shipbuilding companies.

Manufacturing a Ship's Ventilator, H. E. McCauley. Am. Mach., vol. 50, no. 2, Jan. 9, 1919, pp. 47-51, 15 figs. Describes manufacture of American-type ventilator cowls.

Welded Ships

The First Electrically Welded Boat, John Liston. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 844-848, 10 figs. Particulars of boat built in 1915 at Ashtabula, Ohio, and still in service on Great Lakes.

The Adequacy of Welding in Constructing Hulls of Ships, H. M. Hobart. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 840-843. Author expresses belief in adequacy of method.

Rules for Electrically-Welded Ships. Jl. Engrs. Club, St. Louis, vol. 3, no. 6, Nov.-Dec. 1918, pp. 331-334. Regulations adopted by general committee of Lloyd's Register of Shipping, London. From Nauticus, Sept. 7, 1918.

YARDS

Reduction Gears

Mechanical Reduction Gears, J. A. Davies. Jl. Am. Soc. Naval Engrs., vol. 30, no. 4, Nov. 1918, pp. 705-727, 11 figs. Formulæ for designing pinions; considerations on selection of material for bearings; types of couplings; undesirability of flexible couplings in high-powered, high-speed machinery; contour used for teeth of marine reduction gears of double-helical type; accidents and changes due to wear or operation.

Shipbuilding. United States and Canada

Shipbuilding Development in the United States and Canada, W. R. Gray and Edward F. Clarke. Engineering, vol. 106, no. 2765, Dec. 27, 1918, pp. 740-742, 3 figs. Paper before North-East Coast Inst. of Engineers and Shipbuilders, December 1918.

Shipyards

Recent Developments in Shipyard Plants, S. M. Henry. Int. Mar. Eng., vol. 24, no. 2, Feb. 1919, pp. 74-76. From a paper before the Society of Naval Architects and Marine Engrs.

Welding

Electric Welding in Navy Yards, H. G. Knox. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 849-859, 20 figs. Arc-welding and resistance welding processes as related to their general application in navy yard; work conducted in each type of shop; recommendations as to kinds of welding equipment desirable; figures of speed and cost of welding ship structures.

Organization and Management

ACCOUNTING

Ice-Plant Auditing

Auditing and Supervision of Ice Plants, George E. Wells. Ice & Refrigeration, vol. 56, no. 1, Jan. 1919, pp. 48-49. Proposes auditing engineering conditions in a plant and gives particulars and audit forms for ice plants.

Appraisals, Industrial

Three Industrial Appraisals in One, Charles W. McKay. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 141-143. For excess-profits tax computation, for plant accounting and for insurance adjustment.

EDUCATION

Agricultural Instruction

Reference Material for Vocational Agricultural Instruction. Federal Board for Vocational Education, bul. 13 and 14, March and June 1918, 42 pp. and 25 pp. March: Outlines provisions to be made by states for meeting requirements of Smith-Hughes Act relating to agricultural instruction. June: Suggestions for cataloging and filing, bulletin, report, etc., for agricultural education.

Airplane Mechanics

Emergency War Training for Airplane Mechanics. Federal Board for Vocational Education, bul. no. 12, April 1918, 62 pp. Outline of course in airplane construction and repair.

Crippled Soldiers

The Evolution of National Systems of Vocational Reëducation for Disabled Soldiers and Sailors. Douglas C. McMurtrie. Federal Board of Vocational Education, bul. 15, May 1918, 318 pp., 33 figs. Fundamental principles of rehabilitation; categorical description of methods for vocational rehabilitation in force in the various warring countries, including Germany and Austria-Hungary; extensive bibliography of American and foreign literature, inclusive of news items in periodicals, relating to vocational rehabilitation.

Cripples

Reducing the Cost of Disability, Douglas C. McMurtrie. Iron Age, vol. 103, no. 6, Feb. 6, 1919, pp. 362-363. Rehabilitation restores and may enhance earning capacity; insurance costs lessened; the economy of liberal medical attention.

The Conservation of Industrial Man Power, Arthur J. Westermayr. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 504-506, 3 figs. Question of rehabilitating crippled soldiers; how vocational rehabilitation act will be operated.

Engineering Colleges

The Effect of the War on Engineering Education, C. R. Mann. Bul. Soc. Promotion Eng. Education, vol. 9, no. 4, Dec. 1918, pp. 108-118. War experiences analyzed under (1) production of soldiers, and (2) production of supplies. Present college curricula described as aiming to impart knowledge of physical laws and properties of materials exclusively, and as insufficient to develop men who will accomplish reorganization of industrial production, for which task an understanding of the methods by which human wills are coördinated for team play is essential.

Export and Shipping

Vocational Education for Foreign Trade and Shipping. Federal Board for Vocational Education, bul. 24, Nov. 1918, 85 pp. Present importance of education for foreign trade; advanced courses in shipping; coöperative plans for teaching foreign trade; study outlines of fundamental courses; suggested study plans.

Industrial Education

Industrial Education in Wilmington, Delaware. Department of Interior, Bur. of Education, bul. 25, 1918, 97 pp. Report of survey made under direction of Commissioner of Education; suggestions for program of industrial education.

Industrial Schools

Buildings and Equipment for Schools and Classes in Trade and Industrial Subjects. Federal Board for Vocational Education, bul. 20, Nov. 1918, 75 pp., 25 figs. Type schools and classes; detailed description of building and equipment for a trade or industrial school; equipment, courses of study, and methods of instruction in carpentry.

Evening Industrial Schools. Federal Board for Vocational Education, bul. 18, Sept. 1918, 55 pp. Possibilities in evening schools under provisions of Smith-Hughes Act; suggestive courses which have been prepared and carried out at evening schools; approved methods of establishing and conducting evening industrial schools for trade workers.

Italy

Need for Increased Technical Education in Italy (Per l'avvenire della industria meccanica in Italia), G. Belluzzo. Industria, vol. 32, no. 21, Nov. 15, 1918, pp. 635-637. Points out defects of Italian system of training as at present conducted and outlines a system which follows closely that given in best shops in England and United States. (Concluded.)

Naval Architecture

The Requirements of a Course of Training in Naval Architecture, Lawrence B. Chapman. Bul. Soc. Promotion Eng. Education, vol. 9, no. 4, Dec. 1918, pp. 119-130. Outlines plan in which professional work starts early in course and parallels outside training.

Part-Time Schools

Part-Time Trade and Industrial Education. Federal Board for Vocational Education, bul. 19, Oct. 1918, 51 pp. Need for part-time schools in United States; school, man and employer as factors in promoting part-time education; part-time studies already established in U. S.; continuation schools in England, France and Germany; types of part-time schools; federal aid; principles which should underlie compulsory legislation.

Physical Education

Recent State Legislation for Physical Education, Thomas A. Storey and Willard S. Small. Department of Interior, Bureau of Education bul. 40, 1918, 35 pp. Chronological analysis of laws enacted in eight states since the beginning of the war; analysis of purpose and scope of state laws; principles of state legislation for physical education; state laws for physical education.

Radio Operators

Emergency War Training for Radio Mechanics and Radio Operators. Federal Board for Vocational Education, bul. no. 16, Sept. 1918, 74 pp., 8 figs. Outline of course for preliminary training.

Secondary Education

Cardinal Principles of Secondary Education. Department of Interior, Bur. of Education, bul. 35, 1918, 32 pp. Report of Commission on the Reorganization of Secondary Education, appointed by Nat. Education Assn.

Shop Training

Training Operators at Winchester Plant, W. E. Freeland. Iron Age, vol. 103, no. 3, Jan. 16, 1919, pp. 178-179, 2 figs. Short intensive course in training shop for men; three years' apprenticeship in school for boys; details of system. (Eleventh article of series on Winchester plant.)

The Training Department — Past and Future, John C. Spence. Iron Age, vol. 103, no. 4, Jan. 23, 1919, pp. 237-239. The crippling of one plant for another; real and pretended interest in workmen; some training plans for the common good.

Technical Education, Primary

Toronto Builders' Exchange Urges Forward Movement in Technical Education. Contract Rec., vol. 33, no. 3, Jan. 15, 1919, p. 49. Deputation recommends Ministry of Education that technical schools be owned by Government, that education be made compulsory between 14 and 20 years and that parents decide boy's vocation.

Trade and Industrial Education, Organization and Administration. Federal Board for Vocational Education, bul. no. 17, Oct. 1918, 124 pp. Contains information and suggestion concerning organization and administration of trade and industrial schools and class under Federal law.

U. S. Training Service

The U. S. Training Service and Its Work, Charles T. Clayton. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 103-104. Value of service in saving to manufacturers expense of hiring men; industrial training as a means of lessening turnover and increasing output.

Universities

The Universities and the New World, Geo. F. Swain. Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 12-14. Readjustment of schools and universities to fulfil new demands in education created by general reconstruction of past conditions.

Welders

The Training of Electric Welders, H. A. Horner. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 876-881, 9 figs.

Emergency War Training for Oxy-Acetylene Welders. Federal Board for Vocational Education, bul. no. 11, June 1918, 86 pp., 30 figs. History of development and application of oxy-acetylene in industry and war; U. S. Army course of instruction in oxy-acetylene welding and oxygen cutting.

Operators and Instructors Necessary for Electric Arc Welding. Elec. Ry. Jl., vol. 53, no. 4, Jan. 25, 1919, pp. 191-192, 4 figs. From 1918 report of Committee of Association of Railway Electrical Engineers.

The Future of Army Welding Schools, Cyrus K. Rickel. Jl. Acetylene Welding, vol. 2, no. 7, Jan. 1919, pp. 331-335, 7 figs. Discusses qualifications of successful welding school.

Women Workers

Little Causes and Great Effects (Petites causes et grands effects), Francois Villain. Société Industrielle de d'Est, bul. 142, Nov. 1918, pp. 7028, 8 figs. Plea for enforcing law which requires teaching of household arts to young girls in elementary schools; influence of this policy on welfare of women. Conference before the Société Scientifique d'Hygiene Alimentaire.

Training Women for Record Output, Robert I. Clegg. Iron Age, vol. 103, no. 3, Jan. 16, 1919, pp. 169-174, 11 figs. General results abroad and at home; diligence and industry of women; practical system of schooling on shop production lines.

FACTORY MANAGEMENT

Employment Management

The "Conscience" of Modern Industry, C. T. Clayton. Jl. Engrs. Club St. Louis, vol. 3, no. 6, Nov.-Dec. 1918, pp. 352-354. Employment management as a factor to reduce industrial misunderstanding and friction.

Extreme Methods in Employing, Charles M. Horton. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 145-148. Criticises some practices of employment managers.

Industrial Fatigue

A Suggestion for the Prevention of Waste of Human Energy in Factories, H. G. P. Castellain. Cassiers Eng. Monthly, vol. 54, no. 6, Dec. 1918, pp. 303-307. Discusses industrial fatigue from a medical point of view and suggests improvement in medical education and establishment of courses for factory inspectors and medical men.

Investigations

Engineer and Plant Management, J. G. Worker. Aera, vol. 7, no. 6, Jan. 1919, pp. 596-599. Suggestions as to investigations, reports and installations of waste preventing boiler room methods.

Labor Management

Use of Non-Financial Incentives, Robert B. Wolf. Can. Mfr., vol. 39, no. 1, Jan. 1919, pp. 79-80, 2 figs. Stimulating production in industry by internal motives rather than by external discipline, that is, by making comparisons, cost sheets, etc.

Observation

The Value of Observation in Works Practice, H. H. Ashdown. Engineering, vol. 107, no. 2766, Jan. 3, 1919, pp. 11-14, 14 figs. A paper before the Society of Engineers and Metallurgists, Sheffield, Nov. 1918.

Plant Operation

Lifting Power Plant Capacity by Its Boot Straps, Charles L. Hubbard. Factory, vol. 22, no. 1, Jan. 1919, pp. 35-37, 1 fig. Improvements which contribute to increasing efficiency; how superheating steam increases capacity; how increasing speed affects engine; use of compound engines or low-pressure turbines.

Production Control

Graphic Production Control—VI, C. E. Knoeppel. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 113-118, 10 figs. Two ways to tie together and coördinate various features of control mechanism; by use of charts, and by control boards. Last article of series.

Overtime

Graphic Analysis of an Overtime Problem, R von Huhn. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 86-88, 5 figs. Casting delivery on a large contract and amount of overtime needed to machine pieces.

Reports

Facilitating Sewer Pipe Factory Management, W. B. Harris. Brick & Clay Rec., vol. 54, no. 1, Jan. 14, 1919, pp. 39-44, 10 figs. Forms and records of making reports; placing workmen.

Stokers

Power Plant Management: Mechanical Stokers, Robert June. Power House, vol. 11, no. 12, Dec. 1918, pp. 353-355, 2 figs. Efficiency; characteristics of chain grate; instructions for operation.

Storage of Materials

Principles of Purchasing and Storing Applied to Rough, Bulky Materials in Yard Storage, Dwight T. Farnham. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 108-112, 7 figs. Six principles are considered in planning yard storage: Effort required to transport; weight and material to be stored on each square foot of space; rate of stores turnover; storage unit; allotted space; efficient package.

Timekeeping

Providing a Double Check on Timekeeping. Factory, vol. 22, no. 1, Jan. 1919, pp. 48-50, 4 figs. Layout of Eastman Kodak Co. time-clock room.

Water Works

Office Records of the St. Louis Water Division, Distribution Section, Thomas E. Flaherty. Jl. Am. Water Works Assn., vol. 5, no. 4, Dec. 1918, pp. 412-418. Brief description of organization for planning, direction and execution of work.

Welfare Work

Promoting Employees' Welfare Brings Large Returns. Ry. Maintenance Engr., vol. 15, no. 1, Jan. 1919, pp. 5-8, 8 figs. Policies of Richmond, Fredericksburg & Potomac R. R. Co.

FINANCE AND COST

Cost Accounting

Cost Accounting to Aid Production—V, G. Carter Harrison. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 131-139, 4 figs. Diagrams illustrating coördinated cost, planning and production systems. (To be continued.)

Costing at National Factories, W. Webster Jenkinson. Iron & Coal Trades Rev., vol. 97, no. 2643, Oct. 25, 1918, pp. 455-458, 10 figs. Beginning series of articles abstracts from address before London School of Economics and Political Science.

Power Costs

Simple Method of Determining Power Costs, T. H. Fenner. Power House, vol. 11, no. 12, Dec. 1918, pp. 361-363, 1 fig. How to arrive at costs when no instruments are available.

Works Costs

The Economics of Works Costs, J. R. Dick. Elecn., vol. 81, no. 2115, Nov. 29, 1918, pp. 643-645, 2 figs. (First installment of a continued article.)

FOREIGN TRADE

Boilers

New Foreign Markets for American Made Boilers and Boiler Equipment, L. W. Alwyn-Schmidt. Boiler Maker, vol. 19, no. 1, Jan. 1919, pp. 3-4. Exports increased over one-sixth. New fields developed in South America and the Far East. European markets remain on war footing.

Canadian Exports

Canadian Industries and the Export Trade, J. F. Heffron. Can. Machy., vol. 21, no. 1, Jan. 2, 1919, pp. 9-12. Canadian possibilities in developing foreign trade; German credit methods of fostering export trade; articles for export.

Drop-Forge Equipment

Campaigning for Foreign Business, L. W. Alwyn-Schmidt. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 3-6. Suggestions to obtain foreign drop-forge business.

German Methods

Effectiveness and Service in Foreign Trade. Textile World Jl., vol. 55, no. 2, Jan. 11, 1919, pp. 127 and 159. Necessity of considering customer's viewpoint; German commercial vices.

German Foreign Trade Extension Measures, Norman L. Anderson. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 78-79. Private associations for promoting foreign trade; German exhibitions; government trade activities; purposes of suggested "Auslandamt."

Italian Market

Our Opportunities for Foreign Trade, V. Macchi di Cellere. Am. Drop. Forger, vol. 5, no. 1, Jan. 1919, p. 17. Market possibilities of Italy, from address before Am. Mfrs. Export Assn.

INSPECTION

Ordnance Department Methods

How Ordnance is Inspected, Fred H. Colvin. Am. Mach., vol. 50, no. 6, Feb. 6, 1919, pp. 263-267, 8 figs. Description of organization and methods of Ordnance Department for inspection.

LABOR

Bathhouses

Mine Bathhouses in Utah, A. C. Watts. Coal Age, vol. 15, no. 1, Jan. 2, 1919, pp. 4-8, 4 figs. Description of typical bathhouses with comparison of American and European costs.

Blind

An Experiment in Employing the Blind, Dale Wolf. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 105-107. How blind men have been put to work on jig drilling of shackles for locks.

Bonus System

Bonus System in Power Generation, W. L. Whitlock. Nat. Engr., vol. 23, no. 1, Jan. 1919, pp. 9-11, 2 figs. Standing order to employees and scale for computing bonus. System of Denver Tramway Co., which is said to effect saving of $150,000 per year.

Bonus System Reduces Coal Consumption at Denver, W. E. Casey and E. Weber. Elec. Ry. Jl., vol. 53, no. 6, Feb. 8, 1919, pp. 266-271, 7 figs. By installation of new turbine and introduction of bonus system, coal consumption on Denver Tramway System is reduced to less than 2.5 per kw-hr., with saving in operating expense of $150,000 per year.

Coal-Economy bonuses in a Central Electric Power House (Prime au personnel sur les économies de charbon dans une centrale électrique thermique), M. Grospaud. Revue Générale de l'Electricité, vol. 5, no. 2, Jan. 11, 1919, pp. 58-63. From data showing variations in thermal efficiency of coal, writer concludes it is illusory to base bonus system on coal consumption; he proposes instead a system based on scientific and methodic thermal control and outlines its practical working details.

The Engineer—Worker and Organizer, G. W. Tripp. The Central (Jl. City & Guilds Eng. Col.), vol. 15, no. 44, Dec. 1918, pp. 46-54, 1 fig. Comparison between Rowan bonus scheme and system based on 50 per cent payment. Abstract of lecture to Woolwich Arsenal apprentices.

British

Paper on "The Industrial Future," Cecil Walton. Jl. West of Scotland Iron & Steel Inst., vol. 26, pt. 2, session 1918-1919, 19-24 and (discussion) pp. 25-31. Labor conditions and the future development of Glasgow. Reference is made to question of wages.

Labor Administration, Edward T. Elbourne. Engineer, vol. 126, nos. 3282, 3283, 3284, 3285, and 3287, Nov. 22 and 29, Dec. 6, 13 and 27, 1918, pp. 432-435, 7 figs.; pp. 453-454, 3 figs.; pp. 478-480, 5 figs.; pp. 504-507, 5 figs.; pp. 548-550, 4 figs. Nov. 22: Control of production. Nov. 29, The wages office. Dec. 6; Wages office continued. Dec. 13: Accidents. Dec. 27: General discipline and general facilities. (Articles 9-13 inclusive.)

Canada

Education and Coöperation the Wisest Course in Dealing with Labor, Gideon Robertson and T. Moore. Contract Rec., vol. 33, no. 2, Jan. 8, 1919, pp. 19-20. Opinions and suggestions of Canada Minister of Labor and of the President Trades and Labor Congress.

Crippled Workers

Human Reconstruction Reclaims War's Disabled for Industry, W. H. Lloyd. Iron Trade Rev., vol. 64, no. 1, Jan. 2, 1919, pp. 80-86, 11 figs. Courses being offered to disabled soldiers and employments being secured for them.

How to Deal with Our Crippled Workers, T. Norman Dean. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 498-500. Indicates that rehabilitation should be carried on scientifically.

The Conservation of Industrial Man Power, Arthur J. Westermayr. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 504-506, 3 figs. Question of rehabilitating crippled soldiers so that they can stand on their own merits; discussion of rehabilitation vocational act.

Employment Department

The Principles of Employing Labor, E. H. Fish. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 81-85. Fundamental principles underlying establishment and maintenance of employment department, promotion of personal relations. First of five articles.

Federal Control

What Federal Control Has Done for Labor, W. S. Carter. Ry. Maintenance Engr., vol. 15, no. 1, Jan. 1919, pp. 11-12. Résumé of measures taken to improve relations between managements and employees. Abstract from address delivered before convention of Acad. Political Sci.

Housing

Housing the Workers—An Unfinished Job, George Gove. Am. City, vol. 20, no. 1, Jan. 1919, pp. 23-25. Present status of Government housing projects. Challenge to local chambers of commerce to meet emergency.

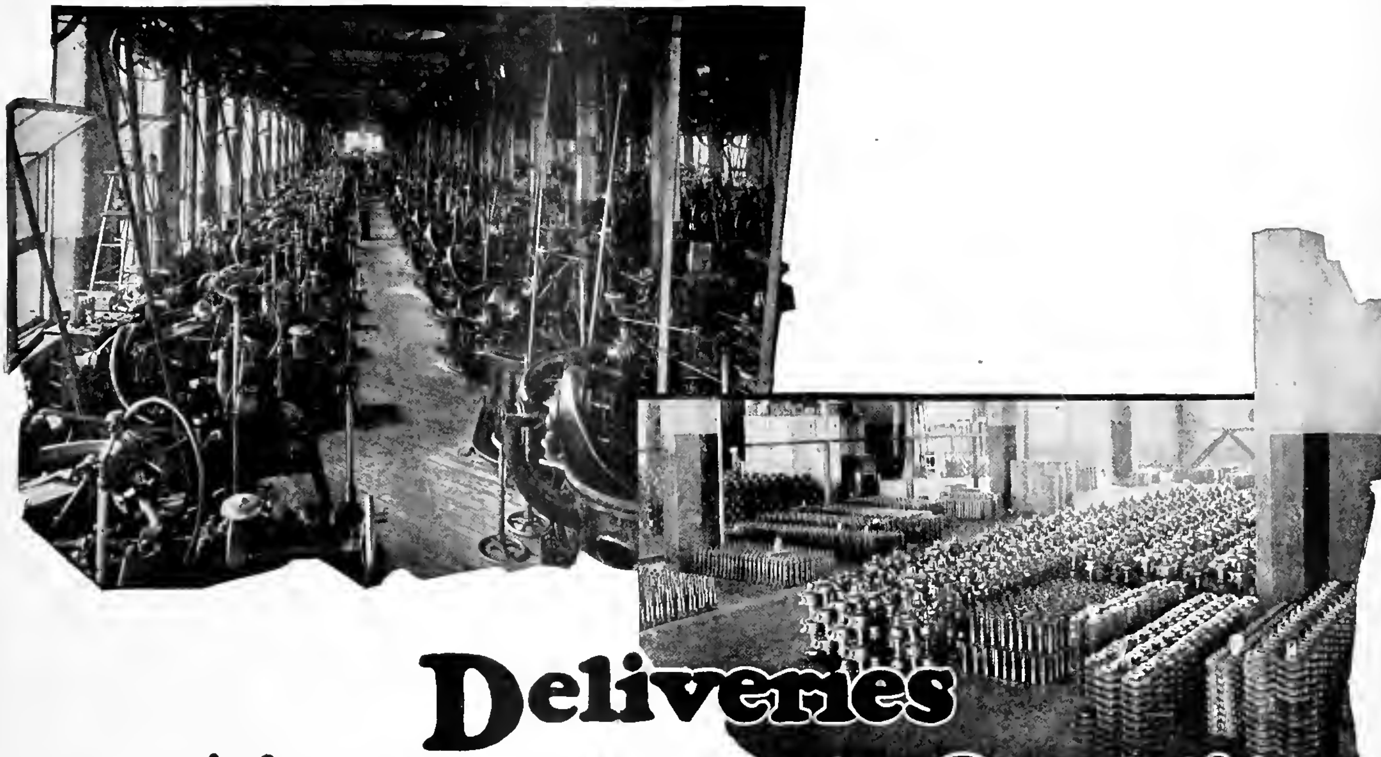
The Present and Future Government of War-Created Communities, Ernest Cawcroft. Jl. Am. Inst. Architects, vol. 6, no. 12, Dec. 1918, pp. 553-558. Suggestions in regard to housing projects undertaken by War Department, Navy Department, U. S. Housing Corporation and U. S. Shipping Board.

Labor Problem

The Labor Problem Analyzed, Magnus W. Alexander. Open Shop Rev., vol. 16, no. 1, Jan. 1919, pp. 3-16. Social, political and economic aspects of labor problem. Address delivered at convention of Nat. Founders' Assn. (To be continued.)

Lunch Rooms

Mill Lunch Room for Employees, A. W. Anderson. Textile World Jl., vol. 55, no. 2, Jan. 11, 1919, pp. 397 and 401, 4 figs. Description of employees' rooms used by several companies.



Deliveries on Time and in any Quantity

Whether it's a rush order for special gears needed on a set date—or gears to be delivered in even quantities on delivery dates running over a long period.

Our plant and physical equipment can absorb your gear business, and handle it with the care and attention it needs—make our deliveries on the specified date without rush, without having to speed up any *one* department beyond the working speed that means careful work.

Your gears will be delivered accurately cut from steel, every ingot of which is tested in our laboratories for agreement with the specifications ordered, and each finished gear tested and checked within the limits set as safe.

There will be no rejects. The gears delivered will be the gears ordered—and the price less than the cost to do this work in your plant.

If you are now cutting your own gears get in touch with us and let us show you how our plant can save you money.

NEW PROCESS GEAR CORPORATION
SYRACUSE NEW YORK

New Process Gears

Older Men

Superannuation of Technical Men. Times. Eng. Supp., no. 530, Dec. 1918, p. 257. Proposes that industrial firms take over policies of technical men in their employment and keep them on same basis as adopted in federation of universities.

Profit Sharing

Enlisting Labor in Production. L. W. Schmidt. Am. Mach., vol. 50, no. 6, Feb. 6, 1919, pp. 253-256, 3 figs. Some methods of making labor interested in the part it is playing in production.

Wage Questions Must Be Handled from Inside the Industrial Unit, Harry Tipper. Automotive Industries, vol. 40, no. 2, Jan. 9, 1919, pp. 62-63. Importance of profit-sharing collective agreement.

Representation of Employees

Where the Men Settle Their Own Troubles. Factory, vol. 22, no. 1, Jan. 1919, pp. 29-31, 1 fig. A board of appeals, consisting of two representatives from each department, one elected by the workers, the other appointed by management, has jurisdiction over all controversies concerning wages, hours of work, discharges, promotions, etc.

Turnover of Labor

Labor Maintenance and Its Indices. Winthrop Talbot. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 127-130, 2 figs. Criticism of accepted theories of labor turnover and methods for computing it as percentage; presentation of theory of labor maintenance and a way of calculating indices to show stability, maintenance and replacement of working force.

Wages

Notes on the Formulæ of Modern Wages (Quelques réflexions sur les formules de salaire moderne). Génie Civil, vol. 73, no. 22, Nov. 30, 1918, pp. 425-428, 5 figs. Graphical representation and study of characteristic functions of form $s/s_0 = f(m)$ where s is actual wages, s_0 wages per day or hour and m activity, i.e., ratio of work actually produced to work corresponding to wages paid.

Labor's Share. Min. & Sci. Press, vol. 117, no. 26, Dec. 28, 1918, pp. 864-866. Conditions brought about by abnormal requirements of war; objections raised by workmen to changing war scale.

The Human Factor in Shop Production. Margaret K. Strong. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 489-490. Points out that high wages gives high productiveness because workman who is well fed and nourished can do greater amount of work.

Wages in War and in Peace. Open Shop Rev., vol. 16, no. 1, Jan. 1919, pp. 19-23. Impossibility of maintaining present high wages.

The Modern Wage Rates and the Public Works and Construction (Les tarifs de salaire moderne et l'entreprise de travaux publics et du bâtiment). G. Bouf. Génie Civil, vol. 74, no. 1, Jan. 4, 1919, pp. 9-11, 1 fig. Study of Taylor's system of rational wages; instituting bonuses.

Women

The Employment of Women in Acetylene Welding, Helen G. Fisk. Jl. Acetylene Welding, vol. 2, no. 7, Jan. 1919, pp. 348-354. Abstract of preliminary report of Chicago district ordnance office on activities of women in acetylene-welding field during the war.

The Employment of Women in the Machine Tool Industry. Alfred Herbert. Eng. Rev., vol. 32, no. 6, Dec. 16, 1918, pp. 161-163. Scope for their employment after war; plea for fixing minimum wage or maximum working hours. Text of memorandum submitted by Machine Tool & Eng. Assn. to War Cabinet Committee on Women in Industry.

Mental Function in the Work of Women (La fonction mentale dans le travail féminin). Jules Amar. Comptes rendus des seances de l'Académie des Seances, vol. 167, no. 22, Nov. 25, 1918, pp. 788-791. Psycho-motor reactions in women; physiological examination of their endurance.

Women a Fixture in Electrical Industry. Iron Age, vol. 103, no. 6, Feb. 6, 1919, pp. 353-354, 3 figs. Special provision for employment, welfare and safety are made by the Westinghouse Co.; shop and technical courses are provided.

Women Workers—Have They Made Good? Mary N. Winslow and Edgar E. Adams. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 12-16, 5 figs. Records of past year; part played by women in war-time industries; present problems; fact concerning employment of women in various plants.

LEGAL

Accident Compensation

When is an Industrial Accident? Business Digest & Investment Weekly, vol. 23, no. 3, Jan. 21, 1919, pp. 92-93. Phraseology of compensation insurance laws in various states and legal decisions by different courts in United States and Great Britain.

"Pre-Existing" Condition of the Workman and Its Relation to Compensation for Injury, Chesla C. Sherlock. Am. Mach., vol. 50, no. 2, Jan. 9, 1919, pp. 67-69. Explanation with citations of zone court decisions.

Patent Laws

United States Patent Law and Procedure, E. E. Huffman. Jl. Engrs. Club St. Louis, vol. 3, no. 6, Nov.-Dec. 1918, pp. 335-351. Outline of patent system; suggested changes. Address delivered at joint meeting of Assoc. Eng. Soc., St. Louis.

The Rights to Patents and Inventions, Chesla C. Sherlock. Am. Mach., vol. 50, no. 3, Jan. 16, 1919, pp. 115-118. Quotes some notable decisions in respect to patent rights.

The New Patent Law Drafted for Hungary and Its Influence Upon Engineers (Der neue ungarische Patengesetzentwurf mit besonderer Ruecksicht auf die Stellung der Techniker), Dr. Rudolf v. Schuster, President of Patent Court. Zeitschrift des Oesterr. Ingenieur- und Architekten-Vereines, Vienna, vol. 70, no. 37, Sept. 13, 1918, pp. 399-402. Defends the provisions of the proposed patent law for Hungary. Advocates coöperation of engineers and lawyers.

The Crucial Question of Patents, Robert Hadfield. Eng. Rev., vol. 32, no. 6, Dec 16, 1918, pp. 157-160. How Board of Trade can provide strong stimulus to British scientific and engineering progress by applying its present powers to effect modification of patent law.

Patent Law Amendment. Jl. Instn. Elec. Engrs., vol. 57, no. 277, Dec. 1918, pp. 64-71. Report of patent-law committee adopted by conference of representatives of 30 leading scientific and technical societies, convened by Instn. Mech. Engrs.

The Patent Situation in the United States. Mech Eng., vol. 41, no. 2, Feb. 1919, pp. 147-149 and 199. Report of Patent Committee to the National Research Council.

See also MINING ENGINEERING, Mines and Mining (Laws); ELECTRICAL ENGINEERING, Generating Stations (Legal Liability)

LIGHTING

Industrial Lighting

Artificial and Natural Industrial Lighting, C. E. Clewell. Elec. World, vol. 73, no. 1, Jan. 4, 1919, pp. 22-25, 8 figs. Their interrelations considered; predetermination of artificial lighting requirements; variation in natural lighting intensities; importance of daylight factor; methods of measurement.

Engineering Aspects of Industrial Lighting, C. E. Clewell. Elec. World, vol. 73, nos. 2 and 6, Jan. 11 and Feb. 8, 1919, pp. 68-71 and 260-262, 7 figs. Jan. 11: Industries should take advantage of studies made under stress of war conditions to promote efficiency of production; specific data now available which aid in selection and location of lighting units. Feb. 8: Economic considerations of the accident rate; relation to coal conservation; well-lighted versus poorly-lighted aisles; desirability of more widespread and intelligent use of reflectors for all lamps.

Mill Lighting

Modern Lighting and Power Installation for Canadian Knitting Mill. Elec. Rev., vol. 74, no. 4, Jan. 25, 1919, pp. 127-130, 7 figs. Electrical equipment complete and designed to minimize fire and accident hazards; details of lighting and power facilities.

Progress in Mill Lighting Practice, H. H. Magdsick. Textile World, Jl., vol. 55, no. 2, Jan. 11, 1919, pp. 401 and 403, 5 figs. State and Federal regulations; developments in accessories.

Street Lighting

The Street Lighting of the City of Buffalo, W. F. Schwartz. Am. City, vol. 20, no. 1, Jan. 1919, pp. 48-50, 4 figs. System comprises type C nitrogen-filled lamps, luminous arcs, pendent magnetite arcs, and enclosed carbon arcs, as well as gas lamps of Welsbach boulevard and ornamental types, and gasoline lamps. Number and cost of each type are given.

Yard Lighting

Light as an Aid to the Movement of Materials, A. L. Powell and R. E. Harrington. Ry. Elec. Engr., vol. 10, no. 1, Jan. 1919, pp. 9-13, 7 figs. Expedition of freight handling at transfer platforms and piers. Abstract of paper before Illum. Engr. Soc.

PUBLIC REGULATION

Plant Management

Industrial Economy (Economia Industrial), V. Posada Gavira. Boletin de Minas, vol. 10, nos. 7-9, Sept. 30, 1918, pp. 129-149, 1 fig. Coördination and harmonization of the technical, economical and human elements in industry by central administration, standardization and specialization.

Public Works

A National Department of Public Works, C. E. Grunsky. Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 16-17. Advisability of creating department of public works to be represented in President's cabinet. Gain in efficiency is claimed over present distribution of engineering work under five different departments.

Street Cars

The National Aspect of the Public Utility, Franklin T. Griffith. Jl. Elec., vol. 42, no. 2, Jan. 15, 1919, p. 78. Question of higher street-car fare discussed from standpoint of what may legitimately be done to keep them low.

RECONSTRUCTION

British Plans

England's Vast Plans for Peace Work, Carroll E. Williams. Mfrs. Rec., vol. 75, no. 3, Jan. 16, 1919, pp. 90-92. New shipyards built in record time; building of concrete ships; recommendation of British reconstruction committee on relations between employers and employees; reconstruction of iron and steel business.

Engineering Problems

The Economic Duties of the Engineer, W. R. Ingalls. Eng. & Min. Jl., vol. 107, no. 4, Jan. 25, 1919, pp. 184-190. Engineering problems in reconstruction.

Engineering Societies

What Engineering Societies Should Do to Assist in Providing Work for Soldiers and Others Who Will Soon Be Out of Work. Bul. Affiliated Eng. Societies Min., vol. 3, no. 12, Dec. 1918, pp. 221-222. From Eng. & Contracting.

France

America and Reconstruction in Europe. Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 18-19. Plans of directors and representatives of large power stations and electric lighting plants situated in devastated regions of France; work done by British Ministry of Reconstruction; post-war preparations in Spain.

Helping France an Aid to America, John V. Schaefer. Iron Trade Rev., vol. 64, no. 3, Jan. 16, 1919, pp. 207-208. Sending of vast stores of army construction material and experts to help rehabilitate country urged as a means of solving our labor problem, securing war loan and laying foundation of future trade.

Reconstruction Plans

Industrial Relations After the War, Henry P. Kendall. Textile World Jl., vol. 55, no. 2, Jan. 11, 1919, pp. 121, 247 and 249. Need of constructive plan acceptable to all; basic principles that should control.

The Human Factor in Industry, A. P. M. Fleming. Jl. Instn. Elec. Engrs., vol. 57, no. 277, Dec. 1918, pp. 47-56. Means which make for improvement in material prosperity of those engaged in industry; pressing problems in industrial reconstruction.

Research

Science and the After-the-War Period, George K. Burgess. Jl. Wash. Acad. Sci., vol. 9, no. 3, Feb. 4, 1919, pp. 57-70. Importance, during transition period, of proper balance and distribution of scientific forces; advisability of retaining more than a nucleus of an organization of scientific men in service of Government and especially in military and naval establishments.

Scientific Leadership

Human Instincts in Reconstruction, William Henry Smyth. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 89-91. Suggests leadership of a national council of scientists as means for directing forces of human instincts.

Steel Trade and Shipbuilding

The Steel Trade and Shipbuilding Competition, E. T. Good. Cassier's Eng. Monthly, vol. 54, no. 6, Dec. 1918, pp. 342-345. Interdependence of steel trade and shipbuilding industries; warning against separation of their common interests and against German dumping methods.

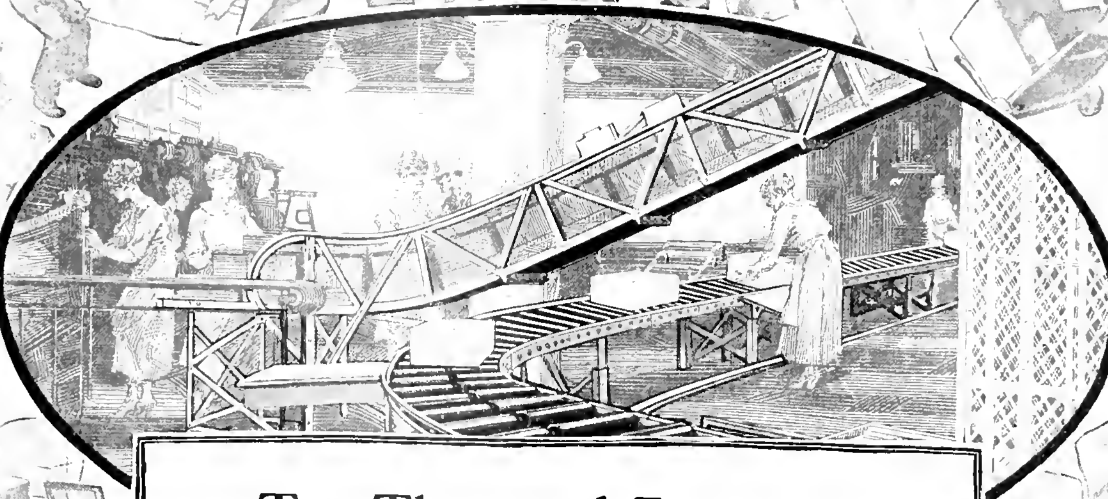
War Developments

War Developments in Industry, Kellaway. Engineering, vol. 106, no. 2763, Dec. 13, 1918, pp. 672-673. Address before Industrial Reconstruction Council, November 1918.

SAFETY ENGINEERING

Accidents and Output

Welfare and Safety. Cassier's Eng. Monthly, vol. 54, no. 6, Dec. 1918, pp. 316-324, 4



Ten Thousand Footsteps You Could Have Saved

WE hear a great deal about overhead charges — but there isn't much said about *underfoot* expense. How much of it is there in your plant? How much does footwork eat into your profits? How much man-power do you employ in toting, carrying and fetching, that *could* be doing a man's real work in production? Yesterday, one man alone took ten thousand footsteps that could have been saved by Lamsonizing your factory.

Lamson Conveyors are the mechanical toters and carriers. They put a stop to footwork and *underfoot* expense. They reduce overhead charges. They collect and deliver parts from one machine room to another. They tote merchandise. They assemble orders and take the goods to the shipping room — and from there to truck or freight-car.

Lamson Conveyors take heavy castings or fragile china to the place that you want them to go. They can't tire. They never lag. They can't make mistakes. Lamson Conveyors operate with orderly, organized regularity. Their route is direct. Nothing can divert them from their work. Their daily capacity is constant—and walls or floors can't stop them.

They go through, while a man goes 'round. They make production flow smoothly and *get the goods out of the works*. The illustration pictures a Lamson Gravity Conveyor. It puts the right thing into the right hands at the right time. Its uses are almost countless.

There's a Lamson Conveying method for every peculiar business, and made to fit *requirements*. Perhaps you need only one Lamson method. It may be that you need a combination. If you are using man-power for toting, for carrying, for pushing a hand-truck, a Lamson man can quickly show you how the Lamson Idea will make a daily saving that will mean much to you—in hard cash. He'll come at your call. If you prefer, send first for our concise Conveyor Book. We'll start it toward you quick-step.

THE LAMSON COMPANY
BOSTON, MASS.

LAMSON SERVICE

Lamson Conveyors

figs. Effect of industrial accidents upon output; means whereby incidence of industrial casualties may be considerably diminished.

Cement Industry

Safety Hazards of Cement Industry, O. C. Soderquist. Concrete Mill Section, vol. 14, no. 1, Jan. 1919, pp. 11-12. Itemizes cement-mill dangers and suggests safety principles and rules.

Fire Protection

Automatic Sprinklers for Fire Protection, Arthur Bateman. Domestic Eng., vol. 86, no. 2, Jan. 11, 1919, pp. 81-83, 4 figs. Notes on their construction, installation and operation.

Grain-Dust Explosions

Experiments with Grain Dust Explosions, Earle William Gage. Am. Miller, vol. 47, no. 2, Feb. 1, 1919, pp. 137-138, 4 figs. Investigations to determine possible cause of explosion and to test various preventive measures.

Lighting

Relation Between Light Curtailment and Accidents, R. E. Simpson. Nat. Engr., vol. 23, no. 1, Jan. 19, 1919, pp. 6-8. Survey of accidents due to improper or inadequate illumination; effect of diminished lighting; suggestions. Paper presented at convention of Illum. Eng. Soc.

Overheating Workmen

The Problems of Overheating Workmen, Chesla C. Sherlock. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 506-507. Methods of protecting workmen who are in contact with high temperatures; liabilities of employer.

Safety Fuse

Use and Abuse of Safety Fuse. Eng. & Min. Jl., vol. 107, no. 5, Feb. 1, 1919, pp. 229-231. Abstracted from bul. 9 of Indus. Accident Commission, Cal.

See also RAILROAD ENGINEERING, Safety and Signaling Systems.

SALVAGE AND WASTE PREVENTION

High-Speed Steel

The Salvage of High-Speed Steel Tools. J. H. Vincent. Am. Mach., vol. 50, no. 4, Jan. 23, 1919, pp. 169-170, 4 figs. Salvaging milling cutters at comparatively small cost by method of grinding without drawing temper of cutter.

Rust Prevention

Rust Prevention as a Steel Conservation Measure, Denis O'Brien. Elec. Ry. Jl., vol. 53, no. 5, Feb. 1, 1919, pp. 243-244. Writer's experiences in removing rust from steel cars and preventing its spreading to a damaging extent.

Scrap

Saving the Waste with an Electric Furnace, C. B. Merrick. Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 30-31, 5 figs. Installation of a two-phase Rennerfelt furnace of 750-lb. capacity by Pacific Foundry Co. to utilize small pieces of waste iron such as nails, borings, etc.

Scrap Organization and Scrap Salvaging, Charles A. Reagan. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 47-48. Work of the Stores and Scrap Section of Ordnance Department; suggestions in regard to scrap segregation.

Waste Utilization

Possibilities in Saving and Utilizing Industrial Wastes, H. E. Howe. Indus. Management, vol. 57, no. 2, Feb. 1919, pp. 92-96. Points out three responsibilities of manufacturers: To use material of no higher grade than necessary for proper production of goods; to reclaim every particle where a salvaging process is known; to search for means to utilize wastes now thrown away.

TRANSPORTATION

Industrial Trucks

Shop Trucks. Am. Drop Forger, vol. 5, no. 1, Jan. 1919, pp. 18-22, 16 figs. Discussion and description of different types of industrial trucks.

Electric Truck as a Means of Shop Transportation. Can. Machy., vol. 21, no. 5, Jan. 30, 1919, pp. 103-105, 4 figs. Illustrates uses of electric storage battery trucks in industry for automatic transportation in loading and unloading ships and railway cars, and in the machine shop, tire factory, textile mill and electric wire insulating and manufacturing plants.

Industrial Electric Trucks, Tractors and Narrow-Gage Locomotives, Raymond J. Mitchell. Elecn., vol. 82, no. 2121, Jan. 10, 1919, pp. 51-57, 16 figs. Conditions under which electric trucks are to be desired; rapidity with which goods may be handled; main features of electric trucks now on the market; results achieved at the Natua Transfer Station of Pennsylvania Railway.

See also MINING ENGINEERING, Mines and Mining (Cars, Mine); MECHANICAL ENGINEERING, Handling of Materials; Hoisting and Conveying.

VARIA

Acceptances

Trade Acceptances in the Forging Trade, M. A. McCann. Am. Drop Forger, vol. 4, no. 12, Dec. 1918, pp. 475-477. Presents different phases of subject from viewpoint of salesman. Method of procedure explained.

Engineering Societies

American Engineers Locally and Nationally Associated, Alfred D. Flinn. Jl. Cleveland Eng. Soc., vol. 11, no. 3, Nov. 1918, pp. 163-173 and (discussion) pp. 173-178. Plea to engineering organizations to give earnest consideration to problem of coöperation; brief account of growth of Founder Societies and creation of Engineering Foundation; service given by the Engineering Societies Library; advisability of publishing an Engineering Societies periodical.

Engineers

What the War Has Done for Engineers, and the Part Engineers Have to Play in Reconstruction. Engineer, vol. 127, no. 3289, Jan. 10, 1919, pp. 41-42. Abstracted from the Presidential Address of R. E. B. Crompton before the Junior Institution of Engineers.

International Chapters

A New Factor in World Commerce, Richard S. Harvey. Textile World Jl., vol. 55, no. 2, Jan. 11, 1919, pp. 127 and 197. Considerations on advisability of forming international chapters for commercial corporations.

Social Problem

Organizing the State to Assist Individuals—A War Lesson (Die allgemeine Naehrpflicht in Licht der Kriegserfahrung), Max Singer. Zeitschrift des Oesterr. Ingenieur-und Architekten-Vereines, vol. 70, no. 38, Sept. 20, 1918, pp. 409-411, Part 1. Indorses the principles propounded by Josef Popper-Lynkeus, that it is the duty of the State to enable each individual to make a fair and useful living. Discusses solutions of the social problem. Part 2 in no. 39, concluded in no. 40, Oct. 4, 1918.

Industrial Technology

Alcohol

A New Opening for the Electrometallurgical Industry. The Manufacture of Alcohol from Calcium Carbide (Un nouveau débauché pour l'industrie électro-métallurgique. La fabrication de l'alcool en partant du carbure), Revue Générale de l'Electricité vol. 4, no. 24, Dec. 14, 1918, p. 934. A current of acetylene is passed over dilute solution of sulphuric acid having mercury salts as catalyser; resulting acetaldehyde is boiled and vapor passed over layer of finely powdered nickel. From Chemische Technische Wochenschrift, vol. 23, p. 55.

Ammonia

Commercial "Concentrated Ammonia-Liquor" and Its Impurities, H. G. Colman and E. W. Leoman, Jl. Soc. Chem. Indus., vol. 37, no. 24, Dec. 31, 1918, pp. 319T-323T and (discussion) 323T-324T. Analyses of samples from different plants.

Barium

Future of the Barium Industry—A Protective Tariff Required, Hugh Rollin. Mfrs. Rec., vol. 75, no. 3, Jan. 16, 1919, p. 97. Importance of industry and its present undeveloped stage in U. S. Paper before Am. Inst. Chem. Engrs.

Benzols

Analysis of Commercial "Pure" Benzols, F. Butler Jones. Jl. Soc. Chem. Indus., vol. 37, no. 24, Dec. 31, 1918, pp. 324T-327T, 2 figs. Experimental determination of depression of freezing point of benzene occasioned by presence of carbon bisulphide, thiophen, toluene and paraffin. A graph gives volume percentages of four solutes in terms of observed temperatures and specific gravity.

By-Products

Relation of By-Products to Chemical Industries, W. H. Blauvelt. Gas Age, vol. 43, no. 1, Jan. 1919, pp 19-21, 2 figs. Industries built up by Semet-Solvay Co. to utilize by-product chemicals.

Carbide

Practical Points on Carbide Sizes. Jl. Acetylene Welding, vol. 2, no. 7, Jan. 1919, pp. 330 and 354. Method of classification according to sizes; relative value of different sizes of carbide. From Bulletin du Journal Suisse d'Acétylène.

Coal-Gas Products

Some Observations concerning (a) Liquid Purification of, and (b) the Simultaneous Recovery of Sulphur and Ammonia from Coal Gas, P. Parrish. Gas Jl., vol. 144, no. 2897, Nov. 19, 1918, pp. 413-418 and (discussion) pp. 418-420, 4 figs. Brief historical account; theoretical phases of processes; design and arrangement of plants; details of Trepex washer; principles governing dissociation; treatment of waste gases. Paper before Southern district Assn. Gas Engrs. & Mgrs.

Coal-Tar Industry Products, British

Progress in the British Coal Tar Industry, J. B. C. Kershaw. Gas Age, vol. 43, no. 2, Jan. 15, 1919, pp. 77-79, 2 figs. English practice in tar distillation and treatment of light oil fraction with dilute caustic soda; brief note on American methods of working up.

Coloring and Lacquering

Approved Practice in Coloring and Lacquering, James Sleetman. Brass World., vol. 14, no. 11, Nov. 1918, pp. 315-317, 6 figs. (Fourth and concluding article.)

Dust Recovery

Dust Recovery from Gas Scrubber Water. Blast Furnace, vol. 7, no. 1, Jan. 1919, p. 48, 1 fig. Dorr thickener installed in blast-furnace plant to provide automatically for settling of dust from gas scrubbers.

Enamels

The Control of the Luster of Enamels, Homer F. Staley. Jl. Am. Ceramic Soc., vol. 1, no. 9, Sept. 1918, pp. 640-647. Effect of crystallization, viscosity, concentrations, sulphur compounds and index of refraction on brilliancy of enamel. Suggestions given are based on considerations regarding chemical and physical phenomena taking place in manufacturing processes.

Fertilizers

Valuation of Fertilizers, J. Alan Murray. Jl. Soc. Chem. Indus., vol. 37, no. 23, Dec. 16, 1918, pp. 317T-318T. Proposes scheme of valuation based on formula, $x = k + np$ where x is price, k cost of production, p percentage of fertilizing ingredients, and n a coefficient which depends upon x and k.

France

Recent Progress and Future Possibilities of the Chemical Industry in France (Les progrès récentes et l'avenir des industries chimiques en France), Paul Razons. Génie Civil, vol. 73, no. 22, Nov. 30, 1918, pp. 429-433. Pharmaceutical products; petroleum distillation; conditions of growth for industry. (Concluded.)

Gas Manufacture

New Signaling Pyrometer a Means of Contending Against Effects of Inferior Labor. Am. Gas Eng. Jl., vol. 110, no. 2, Jan. 11, 1919, pp. 36-37, 2 figs. Lights inform attendant when damaging variation is approached.

The Utilization of Waste Heat in Gas Works (Die Gewinnung und Verwertung der Abwaerme im Gaswerksbetriebe). A technical and economic study by Director Wenger. Journal fuer Gasbeleuchtung, vol. 61, no. 43, Oct. 26, 1918, pp. 509-513, 3 figs. Continued from p. 501. Concluded Nov. 2. Description of experiments made to secure a higher yield of coke from coal. Waste heat used for heating water of municipal bathhouse.

Annual Report of Technical Inspection of Swiss Gas Works (Geschaeftsbericht des Technischen Inspektorates schweizerischer Gaswerke), Journal fuer Gasbeleuchtung, vol. 61, no. 43, Oct. 26, 1918, pp. 505-509, 2 figs. Covers 94 of the 96 gas works of Switzerland and describes equipment used, economies introduced to offset partly the excessively high cost of fuel, accidents, extraction of tar; safety rules and suggestions for further improvements.

Glass Pots

Observations on Apparent Causes of Failure of Lead Glass Pots, A. F. Gorton. Jl. Am. Ceramic Soc., vol. 1, no. 9, Sept. 1918, pp. 648-659. Examination of remains of pots leads writer to conclude that cracking and corrosion are chief causes of failure. Cracks attributed principally to insufficient preheating and corrosion to slagging action of iron on clay.

Helium

The Production of Helium from Natural Gas, Frederick G. Cottrell. Mech. Eng., vol. 41, no. 2, Feb. 1919, pp. 155-158 and 188, 6 figs. Reviews recent work in liquefaction and separation of gases and production of helium for use in balloons.

Lime

Reconstruction and Peace Time Problems of Lime Industry, Charles Warner. Concrete, Cement Mill Section, vol. 14, no. 1, Jan. 1919, pp. 7-9. Address by representative of War Service Committee on Lime at Peace Preparedness Congress.

Nitrogen Products

Nitrogen Industry in Germany during the War (L'industrie de l'azote en Allemagne pendant la guerre). Revue Générale de l'Electricité, vol. 5, no. 2, Jan. 11, 1919, pp. 75-76. Details of partial application of Birkeland-Eyde process and more extensive application of Ostwald process.

Industrial Electrochemical Manufacture of Nitrogenous Compounds: Nitric Acid and its Derivations, Cyanamide, Nitrides (La production électrochimique industrielle des composés nitrés: acide nitrique et derivés, cyanamide, azotures), Jean Escard. Revue Générale de l'Electricité, vol. 4. Scheme of installation for manufacturing nitric acid and nitrates from the air. Following furnaces and processes for producing synthetic nitric acid are described: Birkeland-Eyde, Schonherr, Pauling, Moscicki, Kilburn-Scott and Helbig. Dec. 28: Manufacture of cyanamide by reaction of nitrogen on calcium carbide; fixation of nitrogen in boron, magnesium and calcium nitrides; preparation and properties of these compounds.

Fixation of Nitrogen. Jl. Soc. Automotive Engrs., vol. 4, no. 1, Jan. 1919, pp. 16-17. Electric-arc process; building of concrete dam 100 ft. high and 1 mile long at Muscle Shoals to deliver 500,000 hp. for nitrogen-fixation work; cyanamid and Haber processes.

Note on the Bucher Cyanide Process for the Fixation of Nitrogen, Eugen Posnjak and H. E. Merwin. Jl. Wash. Acad. Sci., vol. 9, no. 2, Jan. 19, 1919, pp. 28-30. Experiments with varying amounts of sodium carbonate, carbon and iron; object to determine whether sodium cyanide was formed by Bucher's reaction.

Potash

Various Methods of Obtaining Potash. Commercial Fertilizer, vol. 17, no. 6, Jan. 1919, pp. 42-46. Developments since 1860.

Rubber

Imitation Caoutchoucs or Vulcanized Oils (Les caoutchoucs factices ou huiles vulcanisées), André Dubosc. Chemie & Industrie, vol. 1, no. 7, Dec. 1, 1918, pp. 727-732. Historical note of development; processes of manufacture; classification.

Railroad Engineering

ELECTRIC RAILWAYS

Braking, Regenerative

Brake System with Recuperation of Energy for Vehicles Operated by Single-Phase Commutator Motors (Système de freinage avec récupération d'énergie pour véhicules actionnés par moteurs monophasés à collecteur), Behn-Eschenburg. Revue Générale de l'Electricité, vol. 4, no. 23, Dec. 7, 1918, pp. 877-881, 5 figs. Description and theory of system adopted at Oerlikon Construction Works for the Saint-Gothard locomotives, which permits operation of brakes with recuperation, at all loads and speeds. A coil of known reactance is only apparatus added to normal installation of motor. Also abstracted in Elecn., vol. 81, no. 2118, Dec. 20, 1918, pp. 708-710, 4 figs.

Coasting Clock

The Electric Coasting Clock. Ry. & Locomotive Eng., vol. 32, no. 1, Jan. 1919, pp. 22-23, 3 figs. Instrument which records actual number of minutes an electric train is operated without use of power or brakes.

Government Ownership

Public Ownership the Obvious Policy for Electric Railways, Richard McCullough. Elec. News, vol. 28, no. 1, Jan. 1, 1919, pp. 27-28. Analysis of present situation; advantages of public ownership to public and investor. Paper before Elec. Ry. Assn.

Locomotives

Oscillations of Electric Locomotives (Oscillations des locomotives électriques), P. Leboucher. Revue Générale de l'Electricité, vol. 4, no. 24, Dec. 14, 1918, pp. 914-930, 35 figs. Mathematical analysis of forces developed in members when continuous torque is transmitted by a crank.

Motor-Generator Sets

Performance of Motor Generator Sets for the Chicago, Milwaukee & St. Paul Ry., F. T. Hague. Elec. Jl., vol. 16, no. 2, Feb. 1919, pp. 47-52, 11 figs. Power-factor curves of synchronous motor, temperature curves at full load and 1.5 load, and direct current short-circuit test at 9.25 load. Special reference is made to commutating machinery of large units.

Track Circuits

The Influence of Zinc Ties on Track Circuits. Ry. Age, vol. 66, no. 5, Jan. 31, 1919, pp. 305-306. Report of discussion at the convention of Ry. Signal Assn.

ELECTRIFICATION

Advantages

Railroad Electrification Facts and Factors, A. J. Manson. Ry. Elec. Engr., vol. 10, no. 1, Jan. 1919, pp. 3-4, 1 fig. Reason for adoption of electric motive power and advantages obtained from its use.

C., M. & St. P.

Chicago, Milwaukee and St. Paul Electrification in Washington, W. A. Scott. Elec. Rev., vol. 74, no. 1, Jan. 4, 1919, pp. 1618, 1 fig. Principal features of power, feeder and trolley lines, substation and locomotive equipment.

France

The Partial Electrification of the French Southern Railway (L'électrification partielle des chemins de fur de la Compagnie d'Orléans). Génie Civil, vol. 74, no. 1, Jan. 4, 1919, pp. 4-9, 4 figs. Program of the Paris & Orleans R. R. Conference before the Société d'Encouragement pour l'Industrie Nationale.

South Africa

S. A. R. Annual Report. S. A. Min. Jl. & Eng. Rec., vol. 28, pt. 1, no. 1416, Nov. 16, 1918, pp. 227-228. Electrification and control of shipping in South African Railways. From report of general manager of railways and harbors.

Western States

Transportation and Western Power Problems, John H. Lewis. Jl. Elec., vol. 42, no. 1, Jan. 1, 1919, pp. 14-15. Suggestions in regard to railway electrification and development of navigable streams.

EQUIPMENT

Cinder-Handling Plant

A New Type of Locomotive Cinder-Handling Plant. Ry. Age, vol. 66, no. 5, Jan. 31, 1919, pp. 319-320, 2 figs. Description of a plant for the Pittsburgh and Lake Erie at Hasleton Yard, Youngstown, O., which includes an inclined hoistway to a storage bin.

Coaling Station

New Philadelphia and Reading Coaling Station. Ry. Rev., vol. 64, no. 5, Feb. 1, 1919, pp. 171-176, 6 figs. Plant arranged to handle both anthracite and bituminous; elaborate sand-handling features; general description of what is believed to be the largest concrete coaling station in the world.

FOREIGN

British

British Railways Under War Conditions. Engineer, vol. 126, no. 3283, Nov. 29, 1918, pp. 454-455, Railwaymen with the colors. (Tenth Article)

Government Ownership, British

Nationalization of British Railways. Ry. Gaz., vol. 29, no. 24, Dec. 13, 1918, pp. 671-674, 1 fig. Factors bearing on policy of railroad Government ownership; discussion of basis for arriving at price which will be fair alike to State and shareholders.

Peru

Peru and Its Principal Railways, Clayton Sedgwick Cooper. Ry. Rev., vol. 64, nos. 1 and 2, Jan. 4 and 11, 1919, pp. 1-5, 6 figs. and pp. 61-65, 8 figs. Geography and history of railway construction in Andes.

LOCOMOTIVES

British Express

The New Express Engines of the London & South-Western Railway. Ry. Gaz., vol. 29, no. 14, Dec. 13, 1918, pp. 662-669, 13 figs. Sectional drawings, photographic illustrations, general dimensions and data of 4-6-0 passenger locomotives recently completed at Eastleigh Works.

Diesel-Electric

Diesel-Electric Locomotives (Automotrices Diesel-électriques). Bulletin Technique de la Suisse Romande, year 44, nos. 14, 15, 16 and 17, July 13 and 27, Aug. 10 and 24, 1918, pp. 129-132, 137-140, 145-149 and 157-158, 13 figs. Extensive descriptions of mechanical arrangement and electrical schemes. A Diesel engine operates a d.c. dynamo; current from dynamo feeds traction motors; Ward-Léonard system followed. Abstract in Revue Générale de l'Electricité, vol. 4, no. 23, Dec. 7, 1918, pp. 891-896, 6 figs.

Feedwater Heating

Locomotive Feed Water Heating, H. S. Vincent. Ry Mech. Eng., vol. 93, no. 1, Jan. 1919, pp. 44-47, 4 figs. Discussion of exhaust-steam and waste-gas methods of preheating for locomotive boilers. (Second article.)

Fireboxes

A New Departure in Firebox Construction. Ry. Rev., vol. 64, no. 2, Jan. 11, 1919, pp. 47-51, 5 figs. Means of taking advantage of principle of radiant heat transfer.

Lubricators

Force Feed Lubricator. Ry. & Locomotive Eng., vol. 32, no. 1, Jan. 1919, pp. 11-12, 1 fig. Records obtained with Schlacks system of forced-feed lubrication as applied to locomotives.

Mallet

The U. S. Standard Light Mallet Type Locomotive. Ry. Age, vol. 66, no. 5, Jan. 31, 1919, pp. 290-292, 4 figs. 2-6-6-2 wheel arrangement with weight on drivers of 358,000 lb. and tractive effort, compound, of 80,000 lb. Description with principal data and drawings.

Mallet Type Locomotive for Utah Railway. Ry. Rev., vol. 64, no. 3, Jan. 18, 1919, pp. 85-86, 1 fig. Description with principal data of articulated compound built for heavy freight and pusher service.

Mountain Type

Mountain Type Locomotives for the Atchison, Topeka & Santa Fe. Ry. & Locomotive Eng., vol. 32, no. 1, Jan. 1919, pp. 3-4, 1 fig. Particulars of 4-8-2 type recently completed at Baldwin Locomotive Works.

New Zealand Narrow Gage

Express Locomotives for 3-ft., 6-in. Gauge. Engineering, vol. 106, no. 2760, Nov. 22, 1918, pp. 576-579, 31 figs. Principal data, drawings of details, test results and general description of certain locomotives on New Zealond Government Railways.

Pennsylvania 2-10-2

Heaviest 2-10-2 Type Built for Pennsylvania Lines. Ry. Age, vol. 66, no. 4, Jan. 24, 1919, pp. 249-251, 4 figs. Principal data, drawings and description.

Rock Island 2-10-2

Rock Island 2-10-2 Locomotive. Ry. Mech. Eng., vol. 93, no. 1, Jan. 1919, pp. 41-43, 5 figs. New designs of cab and spark arrester; grease lubrication used on crossheads and trailer.

Stokers

New Locomotive Stoker Tested Out on Erie. Ry. Age, vol. 66, no. 3, Jan. 17, 1919, pp. 202-204, 4 figs. Mechanical distribution of coal; maintains light fire and reduces cinder and standby losses.

The Elvin Mechanical Stoker for Locomotives. Ry. Rev., vol. 64, no. 4, Jan. 25, 1919, pp. 132-134, 4 figs. Important features are minimum power requirements and a mechanical means of fuel distribution.

Switches, Geared

Lima Locomotive in Switching Service With the Tennessee Coal, Iron and Railway Company. Ry. & Locomotive Eng., vol. 32, no. 1, Jan. 1919, pp. 10-11, 2 figs. Service given by geared locomotive in industrial switching; its special advantages.

Tenders

Canadian Pacific Railway Locomotive Tenders. Can. Ry. & Marine World, no. 251, Jan. 1919, pp. 11-12, 4 figs. Coal container with slope and bottom sheets independent of tank. Coal automatically delivers itself at shovel sheet without coal passer.

Thermic Siphons

Chicago, Milwaukee & St. Paul Railway Test of Locomotive Equipped with the Nicholson Termic Syphons. Ry. & Locomotive Eng., vol. 32, no. 1, Jan. 1919, pp. 7-9, 1 fig. Principal dimensions, data and performances of two engines. Firebox of one was equipped with Nicholson thermic syphons supporting brick arch; other had ordinary type of arch supported on four 3-in. arch tubes.

Tires

Shrinkage of Locomotive Tyres. Ry. Gaz., vol. 29, no. 25, Dec. 20, 1918, pp. 703-704, 1 fig. Methods adopted at Doncaster Works for determining tire shrinkage and for checking allowance of tires.

U. S. Standard

Two More Standard Locomotives. Ry. Mech. Eng., vol. 93, no. 1, Jan. 1919, pp. 25-30, 12 figs. Heavy 4-8-4 and light 2-10-2 types are well proportioned and have essentially same boiler.

Standard 2-10-2 and 2-8-2 Type Locomotives. Ry. Rev., vol. 64, no. 1, Jan. 4, 1919, pp. 7-12, 9 figs. Principal data and drawings with general description. Two government standard engines whose boilers come nearest interchangeability.

New Locomotives of Standard Design. Boiler Maker, vol. 19, no. 1, Jan. 1919, pp. 1-2, 4 figs. Dimensions of four locomotives recently delivered to U. S. R. R. Administration. Totals of boiler-heating surfaces vary from 1891 to 4285 sq. ft.

NEW CONSTRUCTION

Avlona-Monastir

Avlona-Monastir Railroad Project (Proyecto del ferrocarril Avlona-Monastir). Revista de Obras Publicas, year 66, no. 2257, Dec. 26, 1918, pp. 645-647, 2 figs. General plan for consolidation of various lines into a Trans-Balkan Italian System with ferry boat service across Otranto Canal. From Giornale del Genio Civile.

Kalka-Simla

The Kalka-Simla Railway and Rolling Stock. Engineer, vol. 126, no. 3283, Nov. 29, 1918, pp. 455-458, 18 figs. General illustrated description of railway and of rolling stock.

Katanga

The Katanga Railway. Engineer, vol. 126, no. 3285, Dec. 13, 1918, pp. 501-504, 17 figs. Description of its construction, some engineering features and equipment.

OPERATION AND MANAGEMENT

British

British Railways Under War Conditions. Engineer, vol. 126, no. 3286, Dec. 20, 1918, pp. 528-529. The dispatch of the expeditionary force. Vol. 127, no. 3289, Jan. 10, 1919, pp. 38-39. The first six months.

Freight Handling

Proper Methods of Handling Freight, E. P. Nowlin. Ry. Rev., vol. 64, no. 1, Jan. 4, 1919, pp. 5-6. Introducing scheme of reorganization whereby to reduce loss and damage expense.

French

French Railroads During the War (Los ferrocarriles franceses durante la guerra) Boletin de Minas, vol. 10, nos. 7-9, Sept. 30, 1918, pp. 106-110. Organization and operation. Executive direction of each road in hands of a commission composed of a military officer and a technical expert. From documents published by Chamber of Commerce, Paris, June, 1918

Post-War Conditions

The Railway Situation Created by the War (La crisis ferroviaria antes de la guerra y situacion creada por esta). Revista de Obras Publicas, year 66, no. 2246, Oct. 10, 1918, pp. 509-514. Points out critical financial condition of railways in Spain and generally throughout the world, shown by constantly diminishing scale of profits due to rising expenses for fuel, labor and materials. Financial results obtained by railway working in France, England and Germany for period 1901-1913 are given in tabular form.

Supervision

Supervision, J. L. Wilkes. Ry. Club of Pittsburgh, vol. 18, no. 1, Dec. 19, 1918, pp. 6-17 and (discussion) pp. 17-26. Duties of railroad supervisors; qualifications required to fill position completely; suggestions to supervisors in regard to efficiency in discharge of their functions.

U. S. Railroad Administration

The Federal Railroad Administration of the United States, W. M. Acworth. Ry. Gaz., vol. 29, no. 24, Dec. 13, 1918, pp. 651-660. Historical account of conditions in the railroads during the years of the war, specially since the Government took over their operation. Compiled from newspapers, unofficial reports, private correspondence, and public documents.

PERMANENT WAY AND BUILDINGS

Landslip

A Railway Landslip. Times Eng. Supp., no. 530, Dec. 1918, p. 253. Incidents attending movement of wall at Wembley on Great Central Ry.; method of reconstruction.

Montreal Tunnel

The Canadian Northern Railway's Montreal Tunnel from an Economic Point of View, H. K. Wicksteed. Can. Ry. & Marine World, no. 251, Jan. 1919, pp. 1-5, 1 fig. Economical considerations which decided on selection of tunnel route at Montreal with general reference to economical aspect of tunnel construction in railway lines.

Spikes

Screw-Spikes versus Dog-Spikes. Indian Eng., vol. 64, no. 16, 17, 18, 19 and 20, Oct. 19, 26, Nov. 2, 9, 16, 1918, pp. 223-224, 237-238, 251-252, 265-266, 279-280. Reports of experience on Indian railways of comparative efficiency of dog-spikes and screw-spikes for hard and soft wood sleepers. Following points are touched: holding power, gage keeping, creep holding, ease of maintenance and estimated comparative costs, relative advantages in construction, and relative cracking effect on sleepers. (To be continued.)

Water Tanks

Concrete Railway Water Tanks. Ry. Gaz., vol. 29, no. 26, Dec. 27, 1918, p. 728, 2 figs. Details of type commonly used for settling basins

RAILS

Corrugation

Rail Corrugation. Ry. Gaz., vol. 29, no. 26, Dec. 27, 1918, pp. 725-728, 3 figs. Wheel tire is provided with groove, the corners of which present angular cutting edge or edges. This form is said to prevent tendency of rails to develop corrugation.

ROLLING STOCK

Couplers

Development and Construction of Standard Couplers. Ry. & Locomotive Eng., vol. 32, no. 1, Jan. 1919, pp. 5-6, 4 figs. Review of work done by committees of Master Car Builders' and Master Mechanics' Assns. to standardize various parts and contour of couple.

Northern Pacific Box Cars

Northern Pacific Builds Box Cars. Ry. Mech. Eng., vol. 93, no. 1, Jan. 1919, pp. 37-40, 7 figs. Interesting design of underframe and end on cars being constructed in company shops.

Timber

Use of Treated Timber in Car Construction. Ry. Age, vol. 66, no. 5, Jan. 31, 1919, pp. 295-298. Influence of decay on life of wooden car parts, methods of treating and results secured. From a report presented at the convention of the Am. Wood Preservers' Assn.

Trucks

Car Trucks, L. Brown. Can. Ry. Club, vol. 17, no. 9, Dec. 1918, pp. 17-28 and (discussion) 28-35, 1 fig. Manufacture and mounting of wheels; uses of Master Car Builder's standard mounting; preparation of journal bearings and dust guards; requirements of bolsters; location of brakes.

SAFETY AND SIGNALING SYSTEMS

Car Repairmen

To Prevent Injuries to Car Repairers, H. W. Johnston. Official Proc. Car Foremen's Assn., Chicago, vol. 14, no. 3, Dec. 1918, pp. 13-25, 4 figs. Records of accidents on N. Y. C. R. R. show that accidents are minimized by careful observation of practices of employees and thoughtful instruction of new men as to hazards peculiar to work; hence responsibility for accidents is placed on foremen.

Grade Crossings

The Prevention of Accidents at Grade Crossings, C. L. Addison. Am. City, vol. 20, no. 1, Jan. 1919, pp. 7-10, 1 fig. Plan of the grade-crossing publicity campaign conducted by Long Island R. R. Co.; means of grade-crossing protection.

SHOPS

Balboa Shops

War Time Work at Balboa Shops, Panama Canal, R. D. Gatewood. Am. Mach., vol. 50, no. 5, Jan. 30, 1919, pp. 191-194, 11 figs. A brief description of some of the great variety of work being done at the Balboa shops.

Supervision

Efficient Supervision of Railroad Shops, Frank McManamy. Boiler Maker, vol. 19, no. 1, Jan. 1919, pp. 4-5. Locomotive mileage increased by speedy repair work at roundhouse; essentials of adequate supervision; responsibility of executives.

Welding

Arc Welding in Railroad Shops, B. C. Tracy. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 887-898, 20 figs. Describes more important applications of electric welding in making locomotive repairs.

West Burlington Shops

West Burlington Shops of the C. B. & Q. Ry. Mech. Eng., vol. 93, no. 1, Jan. 1919, pp. 5-16, 21 figs. Equipment and operation of new erecting and machine shop, blacksmith shop and power plant.

SPECIAL LINES

Narrow-Gage Railroads

Narraw-Gage Railroads (Chemins de fer à voie étroite), G. Mangin. Génie Civil, vol. 73, no. 26, Dec. 1918, pp. 504-510, 32 figs. Material used in construction of German strategical military railways. Gage 23.6 in. (60 cm.). Data taken from inspection of evacuated areas. Organization of road construction given from official documents left in field by retreating Germans. Supplements article in Génie Civil, vol. 72, no. 14, Apr. 6, 1918, p. 229.

STREET RAILWAYS

Emergency Work

Some Emergency Special Work Construction, Thomas B. McMarth. Elec. Ry. Jl., vol. 53, no. 3, Jan. 18, 1919, pp. 145-146, 4 figs. Indianapolis company utilizes acetylene cutting and thermit welding in building up curve crosses.

Fares

Is the Zone System the Fare Solution? Thos. Conway, Jr. Elec. News, vol. 27, no. 24, Dec. 15, 1918, pp. 29-31. Comparison of fare collection and regulation systems used in U. S. Paper before Am. Elec. Ry. Assn. Also in Street Ry. Bul., vol. 18, no. 12, Dec. 1918, pp. 519-521.

Franchises

Features of Service-at-Cost Plan Franchise. Elec. News, vol. 28, no. 1, Jan. 1, 1919, pp. 29-30. Ordinance containing following principal provisions: General transfer system; complete control of service and operation by city; right of city to reroute; authority of council to order extensions and establish new and additional routes; and franchise tax to be paid to city.

Motors, High-Power

High Power Motors in Tramway Service (Sur l'emploi de moteurs puissants par les tramways), Lucien Pahin. Industrie Electrique, year 27, no. 636, Dec. 25, 1918, pp. 464-467, 6 figs. Equipment of 95-hp. Westinghouse motors used by the Compagnie de Chemins de fer de Paris.

Skip Stops

Skip-Stop Proves Safety Measure. Electric Traction, vol. 15, no. 1, Jan. 15, 1919, pp. 4-6, 3 figs. Diagrams showing reduction in hazard of collisions and boarding and alighting with skip-stop operation, prepared from records of Detroit United Ry.

Tests

Car Equipment Service Tests Determine Fitness of Apparatus, C. W. Squier. Elec. Ry. Jl., vol. 53, no. 3, Jan. 18, 1919, pp. 128-133, 12 figs. Method of making operating tests and heat runs; how sections of track can be best laid out to represent actual service requirements; organization necessary for proper test force; results obtained in specific case.

Track Circuits

Leakage Resistance of Electric Railway Roadbeds, E. R. Shepard. Elec. Ry. Jl., vol. 53, no. 4, Jan. 25, 1919, pp. 172-178, 7 figs. Results of tests covering a period of more than three years made upon railway tracks in Washington, D. C., and upon short sections of experimental track on the Bureau of Standards grounds.

Track Construction

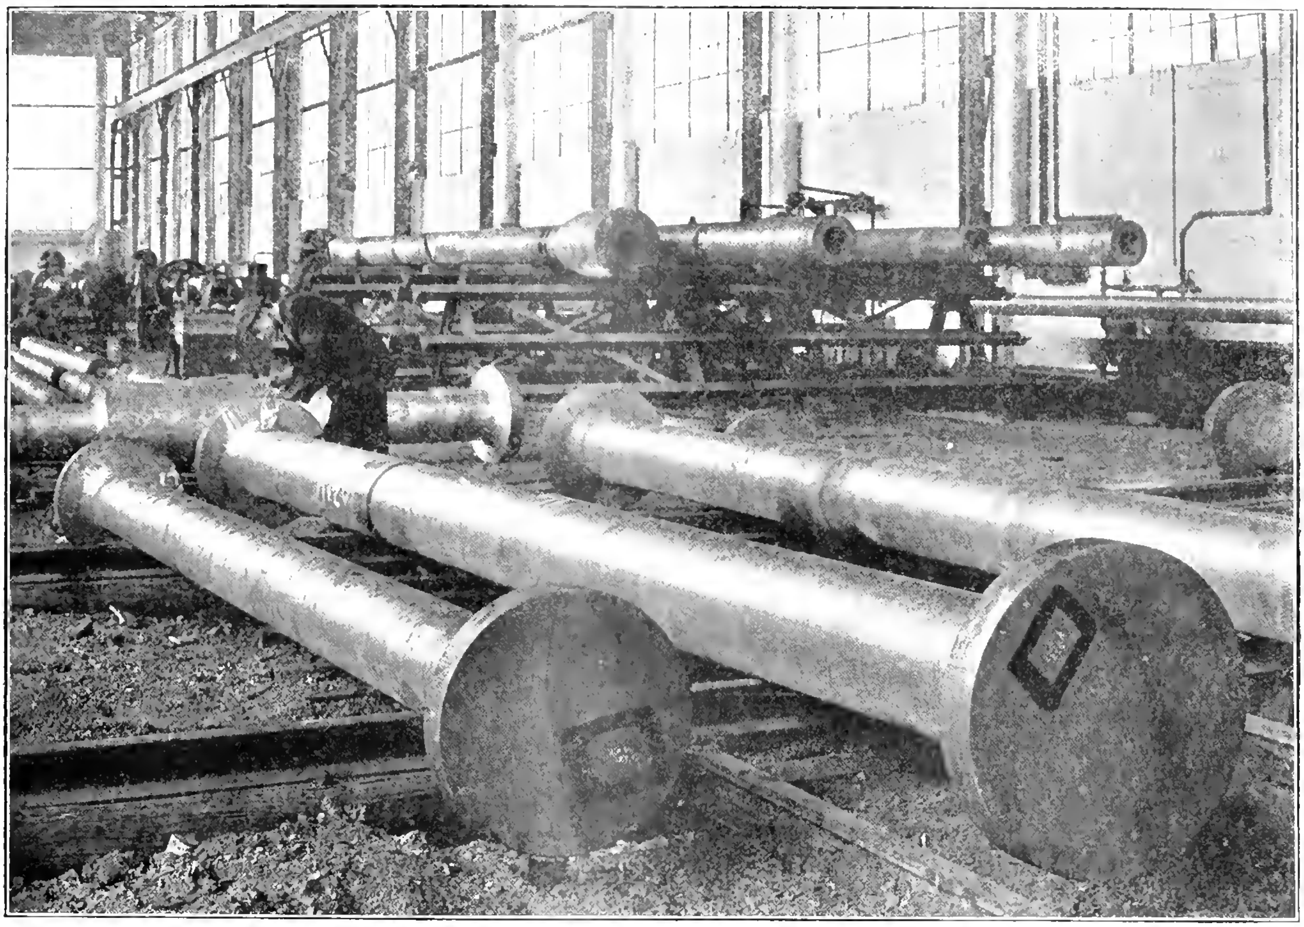
Removing Old Paving for New Track Construction, C. W. Geiger. Elec. Traction, vol. 15, no. 1, Jan. 15, 1919, pp. 30-31, 8 figs. To cut through asphalt a flange was heated and shrunk onto roller of a heavy steam-roller; flange was then sharpened so as to cut down through asphalt when roller was run over it.

TERMINALS

Cleveland Union Station

Union Depot Project for Cleveland, W. E. Pease. Jl. Cleveland Eng. Soc., vol. 11, no. 3, Nov. 1918, pp. 179-185 and (discussion) pp. 185-191. Studies of traffic movements undertaken at New York preliminary to designing some of its terminals; application to conditions in Cleveland.

CAMDEN



COMING THRU

our shops we can see all types and sizes of forgings. Some are smooth forged, some rough turned and some finished complete. We call them all

CAMDEN FORGINGS

If you could but see this variety and could but know of our product and of us, there would surely come a time when you would say,

"SEND CAMDEN THAT FORGING INQUIRY"

BUYERS' MEMO

High and Low Carbon Bars

Analytical Chemistry

Method of Least Squares Applied to Estimating Errors in Coal Analysis, J. D. Davis and J. G. Fairchild. Department of Interior, Bur. of Mines, Tech. Paper 171, 36 pp., 6 figs. Following limits of error are calculated: for sampling, 0.20 per cent; for ash determination, 0.40 cent; for moisture determination, 0.20 per cent; for heating-value determination, 0.75 per cent. Thus writers conclude that limits allowed by committee on coal analysis of Am. Soc. Testing Materials represent values within which a large percentage of errors will actually fall.

Flame Reactions

Flame Reactions: Selenium and Tellurium in the Hydrogen-Air Flame, Jacob Parish. Jl. Phys. Chem., vol. 22, no. 9, Dec. 1918, pp. 640-646. Extension of writer's previous experiments (Jl. Phys. Chem., 22, 430, 1918) to behavior of selenium dioxide, tellurium dioxide, hydrogen telluride, and of elements themselves, in hydrogen-air flame.

Physical Chemistry

Physical Chemistry and Its Bearing on the Chemical and Allied Industries, James C. Philip. Jl. Roy. Soc. Arts, vol. 67, nos. 3450 and 3452, Jan. 3 and 17, 1919, pp. 94-102 and 122-131, 1 fig. Jan. 3: Factors which determine equilibrium in a reversible reaction; thermodynamic equation expressing influence of temperatnre on equilibrium constant of a reaction, and its relation to heat effect of reaction. Jan. 17: Laws and principles governing absorption of gases and dissolved substances.

Structure of Matter

The Atomic Weight of Lead from Samarskite, Arthur L. Davis. Jl. Phys. Chem., vol. 22, no. 9, Dec. 1918, pp. 631-639. Separation of lead from samarskite, its purification, and determination of its atomic weight by means of analyses of lead chloride; parallel experiments with ordinary lead and comparison of relative values under same conditions of experimentation; correlation of results with theory of radioactive changes involved by determination of percentages of uranium and thorium.

The Determination of the Molecular Complexity of Liquid Sulphur, Alex. Mitchell Kellas. Jl. Chem. Soc., vols. 113 and 114, no. 671, Dec. 1918, pp. 903-922, 4 figs. Series of experiments to determine surface tension of liquid sulphur between melting point and boiling point by means of capillary tubes.

Ultra-Violet Light

Ultra Violet Light. Its Application in Chemical Arts—XX, Carleton Ellis and A. A. Wells. Chem. Engr., vol. 26, no. 13, Dec. 1918, pp. 505-506 and 521. Ultra violet absorption of aliphatic ketones and aldehydes. Compilation of researches by different experiments.

MATHEMATICS

Elliptical Functions

Elementary Solution of the Inversion of Elliptical Functions (Solution élémentaire du problème de l'inversion des fonctions elliptiques), René Garnier. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 22, Nov. 25, 1918, pp. 748-750. Generalization of Landen's transformation.

Logarithms

Logarithms of Hyperbolic Functions to Twelve Significant Figures, Frederick E. Pernot and Baldwin M. Woods. Univ. of Cal. Publications in Eng., vol. 1, no. 13, Nov. 16, 1918, pp. 297-467. Tables of logarithms to base 10 of three principal hyperbolic functions for range from 0 to 2 with tabular interval of 0.001, and auxiliary tables of log (sinh x/x) and log (x/tanh x) for range from 0 to 5 with same tabular interval.

PHYSICS

Capillary Layers

Thickness and Structure of a Capillary Layer of a Liquid in Contact with Its Saturated Vapor (Die Dicke und Struktur der Kapillarschicht einer Fluessigkeit in Beruehrung mit ihrem gesattigten Dampf), G. Bakker. Annalen der Physik, vol. 54, no. 20, 1917, pp. 245-295, 5 figs. Discussion of potential function of the forces of attraction. Application to thermodynamics. Comparison of theoretical results in the experimental determinations made on gases, hydrocarbons, water, alcohols, including their freezing points. Mathematical treatment.

Compressibility of Solutions

Compressibility of Aqueous Solutions, Especially of Urethane, and the Polymerization of Water, Theodore W. Richards and Sven Palitzsch. Jl. Am. Chem. Soc., vol. 41, no. 1, Jan. 1919, pp. 59-61, 1 fig. Compressibilities of aqueous solntions of urethane were measured at 20 deg. cent. over pressure range from 100 to 300 megabars, as were also surface tension, specific volume and viscosity. Bearing of results on theory of Harold Whiting ascribing polymerization to water is emphasized.

Heat Conductivity

Experiments on the Heat Conductivity of Gases (Experimentelle Untersuchungen ueber die Waermeleitfaehigkeit der Gase), Sophus Weber. Annalen der Physik, vol. 54, no. 21, 1917, part 1, pp. 325-356, 9 figs.; no. 22, part 2, pp. 437-462, 2 figs. Theory and correction factors employed in accurate determinations of heat conductivity using an electric calorimeter which is a modified Schleiermacher apparatus, applied to air and pure gases at various pressures and suitable for other insulators. For dry air with convection and CO_2 eliminated, $K_0 = 0.000056S1$ gram calories, deg. cent., sq. cm. In part 2 is given the heat conductivity of hydrogen, neon, helium, argon, nitrogen, oxygen, methane, CO_2, N_2O. Tests were conducted at the incandescent lamp works of N. V. Philips, Eindhoven, Holland.

Internal Friction

On the Interior Friction of Quartz Fibers at Low Temperatures (Remarque sur le frottement intérieur des fils de quartz aux basses températures), C.-E. Guye and P. Barbier. Archives des Sciences Physiques et Nautralles, vol. 46, Dec. 1918, pp. 326-328. Experiments to determine cause of slow variation of internal friction as temperature diminishes from +80 to —194 deg. cent.

Radiations

The Gamma Ray Activity of Thorium, D. Herbert N. McCoy and G. H. Cartledge. Jl. Am. Chem. Soc., vol. 41, no. 41, Jan. 1919, pp. 50-53. Determination of Th D; The ratio in order to ascertain whether combined mesothorium and thorium D activities would give total γ activity.

Sound Waves, Reflected

Submarine Range-Finding by Means of Reflected Sound Waves. Sci. Am., vol. 120, no. 4, Jan. 25, 1919, pp. 67 and 82. Modification by Elias Ries of his apparatus for accurate positioning of icebergs. Subaqueous device consists of two megaphone receivers pivoted at ends of horizontal arm and a sound projector mounted in center; operation similar to that of aerial apparatus.

THE LARGE STEAM TURBINE

Development of Large Units to Meet Modern Power Requirements—Records of Performance—Notes on Design and Construction

By J. F. Johnson,[1] Pittsburgh, Pa.

THE remarkable growth of the electric-power industry during recent years has been paralleled by an equally remarkable development of steam-turbine-driven generating units. So rapid has been this development that frequently before the first machine of a new design was completed another of materially greater capacity and higher efficiency was being designed.

While machines of 15,000 kw. capacity were put into operation as early as 1908, their use did not become general until 1913; and yet today nearly every one of what may be called our large generating stations has at least one unit of 30,000 kw. capacity or larger.

Has this growth been natural and healthy, or has it been forced? Will the tendency be toward larger units or will a reversion to smaller sizes occur? If such reversion occurs, will it be the result of faulty engineering, born of overconfidence on the part of the builders or users of the apparatus, or because units of 30,000 kw. and larger are too large for the present and immediate future requirements of our large power-generating stations?

In our chief industrial centers, the electric-power industry has attained its broadest development. Here the appeal of "Do It Electrically" has gained a universal response. As a result power consumption per unit of area has reached high values and this has encouraged the formation of large public-service companies, both by means of development, and by means of consolidation of smaller ones. Moreover, a careful analysis of the present applications of electric power will not disclose a likelihood of serious decrease in any of them. On the other hand, there are many applications in which marked future growth seems certain. Important among these are the separation and purification of metals, the use of the electric furnace in metallurgy, and the electrification of our present steam railroads. There can be no doubt that the electric power industry is today only in the midst of a rapid and healthy growth.

In designing machines of large capacity, the selection of the number and sizes of units in a station of given capacity is most important since this selection materially affects the total cost of power generated. If the sizes of units be too small, the cost per kilowatt of the completed station will be greater, the maintenance and operating expenses higher, the efficiency lower, and the reliability at least no greater than if the proper sizes are used. On the other hand, if the units be too large, the cost per kilowatt installed may be too great because of the greater reserve capacity required, and the efficiency may even be lower by reason of the units operating at loads too far below their points of best efficiency.

Take for example a district with a maximum peak requirement of 600,000 kw. To insure proper reliability it is decided to generate in three stations of approximately equal sizes. Assume that these stations will normally always operate in parallel and that there will be one spare unit for each five in service during the peak. If 20,000-kw. units were used, there would be 30 operating and six spares, a total of 36 units, 12 in each station. If 30,000-kw. units were used, there would be 20 operating and four spares, a total of 24 units, eight in each station. If 40,000-kw. units were used, there would be 15 operating and three spares, a total of 18 units, six in each station. If 60,000-kw. units were used, there would be ten operating and two spares, a total of 12, four in each station.

If, in order to remove from this consideration of ideal size of units conditions imposed by the design of the apparatus, it is assumed that, irrespective of the size, the reliability, efficiency, and purchase price per kilowatt will be the same, then the best results are to be expected with either the 40,000- or 60,000-kw. sizes, because the installation and operating costs would be less per kw.; the efficiency higher because of the higher efficiency of the larger units; and the reliability greater because of the smaller number of operations of starting and stopping and cutting in and out of service of units necessary.

In so far as conditions affected by the design of units are concerned, it is quite generally appreciated that in sizes up to at least 30,000 kw. capacity higher efficiency at the same cost per kilowatt is obtainable purely by reason of the larger size, and a still higher efficiency for a slight increase in cost per kilowatt; and it has been quite conclusively demonstrated that as high a degree of reliability is obtainable in these larger units as in the smaller ones. Fig. 1 shows the approximate relative steam-consumption rate of units varying from 5,000 kw. to 40,000 kw., but all designed for the same cost per kilowatt.

Appreciating the need of generating units of large capacities in the future growth of the electric power industry, the engineering staff with which the writer is associated took up several years ago the work of designing such machines, assured themselves of their feasibility, and advocated their use. A number of them have been in operation several years, and their expected excellence as to reliability and efficiency has been fully verified.

Record of Performance of Large Turbine Units

Up to the present time 14 units have been sold, varying in capacity from 30,000 to 70,000 kw. maximum. Of these 10 have been placed in service and seven of them have been in service for periods varying from 1 to 5 years. The record of these machines in operation should emphatically remove any doubt as to the commercial possibility of units of large capacity, and satisfactorily prove that at least within limits not yet reached, increase in size need not impair reliability, and may improve efficiency.

The first three of these units, which are exact duplicates of each other, were sold to the Interborough Rapid Transit Company of New York. They are of the two-cylinder, cross-compound, pure reaction type; 30,000 kw. maximum rating with point of highest efficiency at 25,000 kw., operating with 205 lb. steam pressure, 120 deg. fahr. superheat and 29 in. of vacuum referred to 30 in. The high-pressure cylinder operates at 1500 r.p.m., and the low-pressure at 750 r.p.m.

The first one was put in service December 30, 1914, the second in February and the third in August, 1915. Very elaborate and exact steam-consumption tests were conducted by the purchaser on the first of these units.[1]

These units have been operating on an average of from 16 to 20 hours per day, on fluctuating railway loads of from 10,000 to 30,000 kw. With the first and third no trouble has been experienced and they have been ready at all times for any service within their designed capacity except during periods of inspection. In the case of the second the labyrinth packing on the balance pistons of the high-pressure element has failed three times, requiring renewal of some parts. The cause of these failures was supposed to have been improper adjustment, but investigations following the third failure indicated excessive lost motion in the thrust bearing and heavy distortional stresses due

---

[1] Engr. Turbine Dept., Westinghouse Elec. & Mfg. Co., Mch. Works. Mem.Am.Soc.M.E.

Abstract of paper presented at a meeting of the Philadelphia Section of The American Society of Mechanical Engineers, November 26, 1918.

[1] See paper by Messrs. H. G. Stott and W. S. Finlay, Jr., presented at May 1916 meeting of New York Section of the A.S.M.E.

to rigid bracing of the steam pipe near the turbine as the probable causes.

The fourth unit, placed in operation in the Northwest Station of Commonwealth Edison Company, Chicago, in September 1917, consists of a tandem-compound, pure reaction turbine, direct-connected to a single generator. It has a rating of 30,000 kw. with an overload capacity of 5000 kw. operating with 220 lb. steam pressure, 200 deg. superheat, 29 in. of vacuum, 1200 r.p.m. (See Fig. 2.)

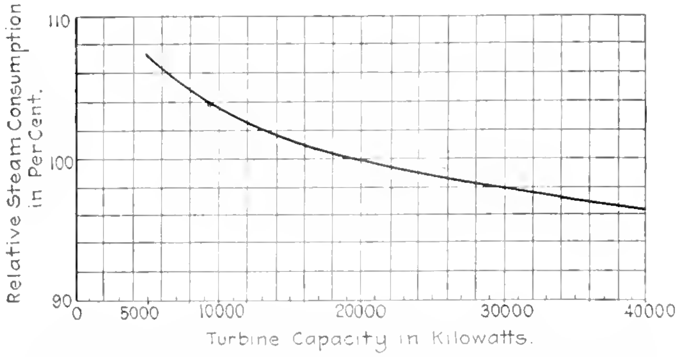

Fig. 1 Relative Steam Consumption for Units of Various Capacities Designed for Equal Cost per Kilowatt

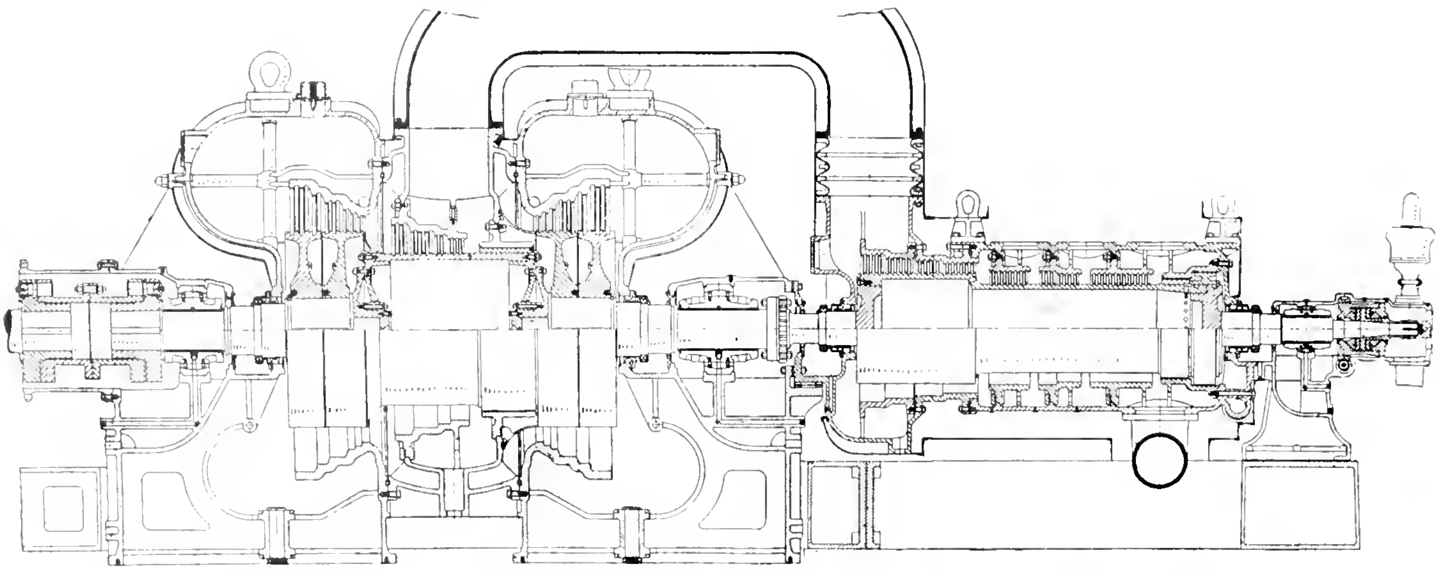

Fig. 2 30,000-Kw. Tandem-Compound Reaction Turbine, Commonwealth Edison Co., Chicago

A few hours after being put into service, subsequent to completion of erection, the labyrinth packing on the low-pressure element failed, due to buckling of the turbine cylinder, caused by rigid piping connections between the two surface condensers, which are bolted rigidly to the two exhaust openings on the turbine, and thus preventing the condensers from translating with the turbine as its temperature increased. Temporary repairs were made locally and the unit put in service in about four weeks. It has been operating almost continuously since carrying loads as high as 40,000 kw. In one instance it was kept on the line for 71 days and then taken off only in order to clean the condenser. Material for making permanent repairs to the labyrinth packing was shipped to the station within a few months after the accident, but the purchaser has not yet given permission to take the unit out of service long enough to install it.

The fifth unit, a 30,000-kw. pure reaction single-cylinder machine, operating on 200 lb. steam pressure, 100 deg. superheat, 29 in. vacuum, was placed in operation in the Gold Street Station of the Edison Electric Illuminating Company of Brooklyn, in October, 1917. Owing to congestion in the shops and urgency of shipment, this turbine was not operated prior to shipment. The overspeed test was made after installation. No correction of balance was necessary, and with the exception of a few leaks in the oiling system, and the breaking of a defective gear on the oil-pump drive, no trouble of any sort has been experienced. It has been available for service at all times and has been operating approximately continuously, except over Sundays and when necessary to clean the condensers, at average loads of approximately 23,000 kw., and peak loads as high as 32,000 kw. (See Fig. 3.)

The sixth unit, placed in service in December, 1917, in the Kent Avenue Station of Brooklyn Rapid Transit Company, is a duplicate of the fifth machine. Immediately after its installation a rebalancing of both turbine and generator rotors was necessary. After having been in service approximately 10 months, the thrust bearing overheated and wiped some, but did not damage any other part of the machine. When opened for inspection it was found that the labyrinth packing strips, which were made of an aluminum alloy, were considerably corroded by the action of strong alkalies used at this plant for treating feedwater; and two rows of blading in the high-pressure portion of the machine were found to have been damaged at some previous time, probably by foreign matter or a defective blade.

The seventh unit is a 40,000-kw., 60-cycle, cross-compound machine, installed in the Brunot's Island Station of the Duquesne Light Company, and placed in service in December, 1917. (See Fig. 4.) The high-pressure element of this machine operates at 1800 r.p.m., and the low-pressure at 1200 r.p.m. This unit has been in regular service carrying loads normally of from 30,000 to 40,000 kw. and peaks as high as 50,000 kw. On February 18, 1918, while operating the machine to correct the balance of one of the generators, the main bearing at the coupling end of the high-pressure turbine burned out, apparently due to interruption of oil service to that bearing. This let the spindle down sufficiently to cause rather heavy blade rubs throughout the machine. The bearing was rebabbitted and the machine put back into service without any other work being done except rechecking the clearances and placing a balance weight on the spindle to correct for the weight rubbed off the blades.

In July the generator was damaged by electrical trouble, and while this repair was being made, both elements of the turbine were dismantled. The high-pressure rotor was returned to the shops and the damaged blading replaced and rebalanced. New blading was also installed in the stator to restore original clearances and original efficiencies. Inspection of the low-pressure element revealed several broken blades which were defective and had slightly damaged the rest of the blading in their rows, requiring replacement of approximately $1\frac{1}{2}$ rows of blading on each end of the machine.

The eighth unit, practically a duplicate of the seventh, rated at 45,000 kw. maximum, was placed in service for the Narragansett Electric Light Company in Providence in January, 1918. In

placing this machine in service the labyrinth packing on the high-pressure was damaged, due to improper adjustment, which necessitated temporary repairs, keeping the machine out of service until about March. Since then no trouble has been experienced except some distortion of the couplings caused by a series of violent short-circuits. Permanent repairs to the labyrinth packing have been made and new coupling parts are to be installed in the near future. In the meantime the old parts are operating satisfactorily without any evidence of distress. This machine operates on loads as low as 5,000 kw., and has carried a peak load of 50,000 kw. for periods of from four to five minutes.

The ninth unit is a 70,000-kw., three-cylinder, cross-compound, 25-cycle machine, installed for the Interborough Rapid Transit Company in New York. The one low-pressure element was placed in service April 18, 1918, operating on high-pressure steam. The high-pressure element was placed in service August 21, operating in connection with the low-pressure already installed, and the second low-pressure element was placed in service October 9.

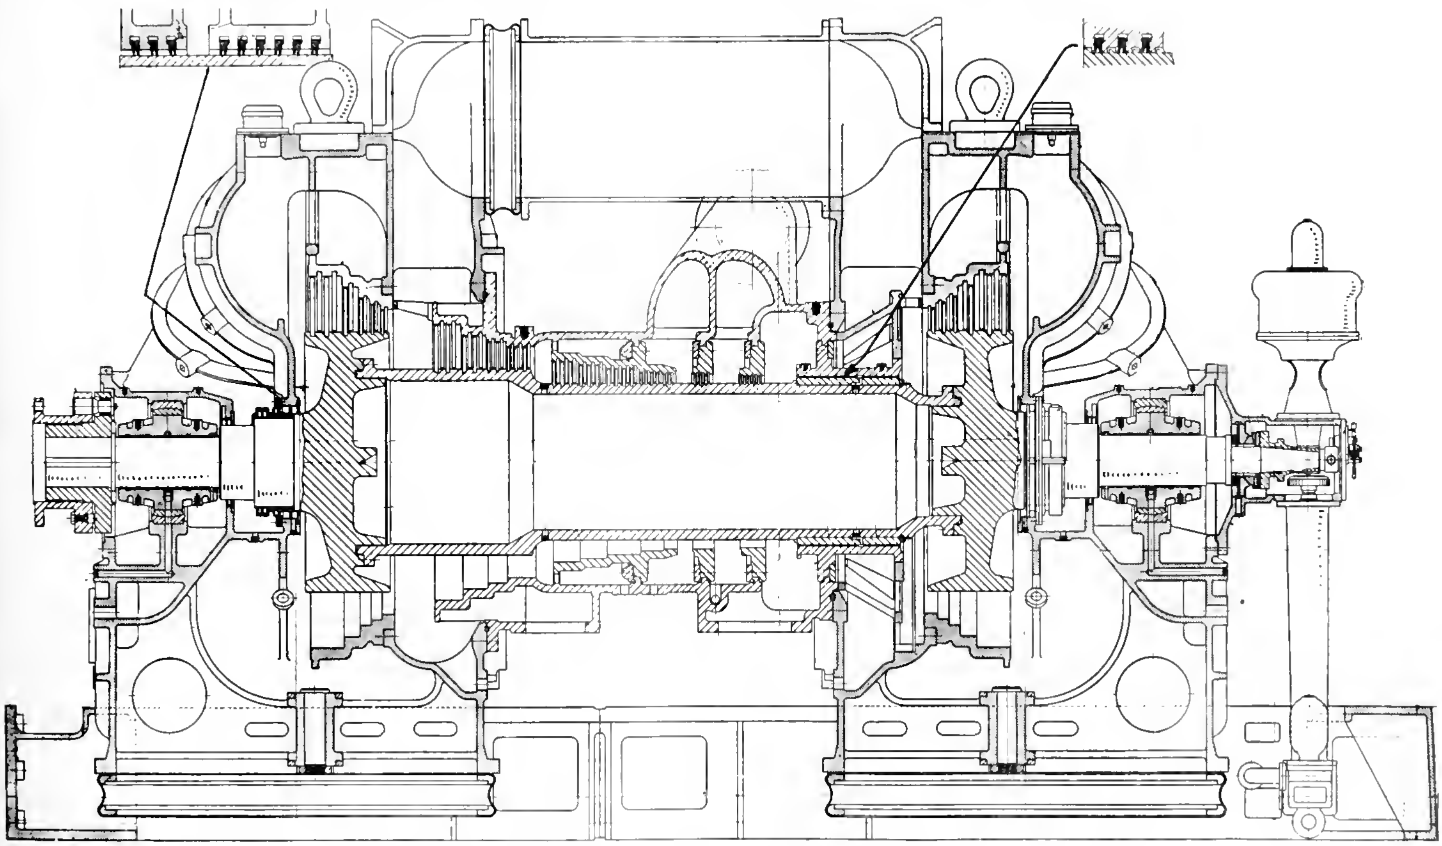

Fig. 3 30,000-Kw. Single-Cylinder Reaction Turbine, Edison Electric Illuminating Co., Brooklyn

Some intermittent vibration trouble appeared on the first low-pressure machine, the cause for which was found to be lack of sufficient clearance on one of the spindle rings, causing distortion during expansion. After this was corrected no further trouble was experienced except the breaking of a few defective blades on the intermediate stage of the second low-pressure element. This unit is equipped with a controlling mechanism for cutting any element out of service, either automatically or manually, without disturbing the other two. These features have been given a thorough tryout, and have verified all expectations as to flexibility. In regular service it has carried loads as high as 55,000 kw. with swings up to 61,000 kw. This turbine is shown in Fig. 5.

While these records do not show perfection in all respects, they do exhibit sufficient evidence to prove that no inherent or basic defects in design or difficulties in construction or operation have been encountered.

With one exception no important part of any one of these units has ever been returned to the works for replacement, alteration, or repair. The high-pressure rotor of the Duquesne Light Company unit was returned to the shops for checking for truth and reblading.

Notes on Design and Construction

The theoretical design of a steam turbine is in itself quite simple. The proper steam path for any assumed rate of steam flow, given the number of stages and areas through each for any assumed blade velocity and ratio of steam velocity to blade velocity, may be determined with the aid of a steam table or sufficiently accurate Mollier diagram.

The successful practical design, however, is quite involved, comprising many problems worthy of the highest engineering skill. Many conflicting factors must be judiciously combined in order to secure the best design and one which will best serve the intended purpose.

In this as in all other arts, experience is the great teacher, and highest success is attained only after years of growth and adherence to the same basic design, the principles of which must be right and therefore susceptible of the highest development.

To begin with, the engineer must have a clear vision of his ideal—his turbine made perfect in every detail. This must be the standard toward which he constantly strives, deviating from it only as compelled to in compromising between conflicting factors. In this ideal *reliability* and *general operative excellence* must stand out as the dominating characteristics, because above all things the machine must be dependable to deliver its rated capacity of kilowatts upon demand; second to this comes *efficiency,* because it must in competition with other units yield a profit for the owner; and third comes *cost*, because the unit must be salable in competition.

Steam Areas

The first and perhaps greatest single problem is suggested in the theoretical design: it is to provide areas suitable to accommodate the enormous increase in volume of the steam while passing through the turbine. Assume steam supplied at the throttle at 250 lb. gage pressure and 150 deg. superheat. This enters the first stage at a pressure of about 255 lb. absolute and specific volume of 2.28 cu. ft. per lb. (allowing 10 lb. drop through the throttle and inlet valves). It leaves the last stage at 380 cu. ft.

per lb. when 28½ in. is maintained by the condenser, and 550 cu. ft. per lb. when 29 in. is maintained; that is, the volume when exhausting to 28½ in. vacuum is 166½ times, and when exhausting to 29 in. is 241 times as large as it is at the entrance. This means that if the rate of steam flow is such as to require an 18-in. steam inlet pipe; and if its velocity were maintained the same through the exhaust as through the inlet pipe then, when expanding to 28½ in. vacuum, the exhaust opening would have to be 19 ft. 4 in. in diameter, and when expanding to 29 in. vacuum 23 ft. 4 in. in diameter. If, further, the mean diameter and exit angle of all the rows of blading be the same and the ratio of blade speed to steam speed be the same in each, thereby keeping the theoretical efficiency of all stages equal, and if these blade and steam speeds be so chosen as to fix the height of blades in the first stage at one inch, the last row would have to be approximately 13 ft. 10½ in. if designed for 28½ in. vacuum, and 20 ft. 1 in. if designed for 29 in. vacuum.

The impracticability of adhering to such proportions in actual designs is obvious.

Rotor Speed and Blade Proportions

Here is where the combining of conflicting factors begins. In the first stages the areas and blade heights should be kept large in order to reduce the losses, and in the low-pressure stages they must be sacrificed on account of practicable limits of mechanical design. In single-cylinder machines where the blading is all on the same spindle, the problem becomes doubly difficult.

The first determination is that of rotative speed which is usually not difficult to make since the frequency of the generator restricts the permissible speeds to a few and these are rather widely separated. The limiting capacities at the various permissible rotative speeds for which generators can be built must also be considered, although at the present time the practicable limits of turbines and generators are reached at approximately the same capacities except in the case of single-phase generators. With these the limiting capacities are very much less than with polyphase generators.

The chief factor in the selection of the rotative speed is the design of the last row of blades with reference to height, diameter and exit angle, because this is the most important stage in the entire turbine. In it the mechanical stresses and fatiguing effect of vibration, the B.t.u. drop, and physical dimensions, are all greatest. Consequently, upon it depends largely the reliability, efficiency, and cost of the unit.

Here must be considered the alternatives of a higher rotative speed with the low-pressure stage made multiflow as against a slower rotative speed and single-flow construction.

The length of blades must not be excessive with reference to the diameter, not only because of the higher stresses in the blades and rotor, but also because the difference in velocity of the blades at their tips and at their roots, as well as the difference in blade spacing, will, if too great, materially impair the efficiency.

On the other hand, if the area through the blades be restricted, the steam velocity will become too high and the bearing losses too great. If this restriction is carried to the extreme, the steam in passing through the last row of blades may reach its critical velocity without expanding entirely down to the condenser pressure, in which event the remainder of the expansion takes place in the form of an explosion upon leaving the blade passages, and from it only a small percentage of the energy is recovered.

In order, therefore, to secure the most satisfactory design for the last stages, and to permit the stresses or physical dimensions with the ever-present cost from becoming prohibitive, several compromise features should be employed.

The first of these consists of increasing the rotor diameter and blade heights, until the safe limit of stress is reached, keeping the blade height within approximately one-fourth of the rotor diameter as a limit of good practice. The materials of which the rotor and blades are made will of course determine the safe stres-

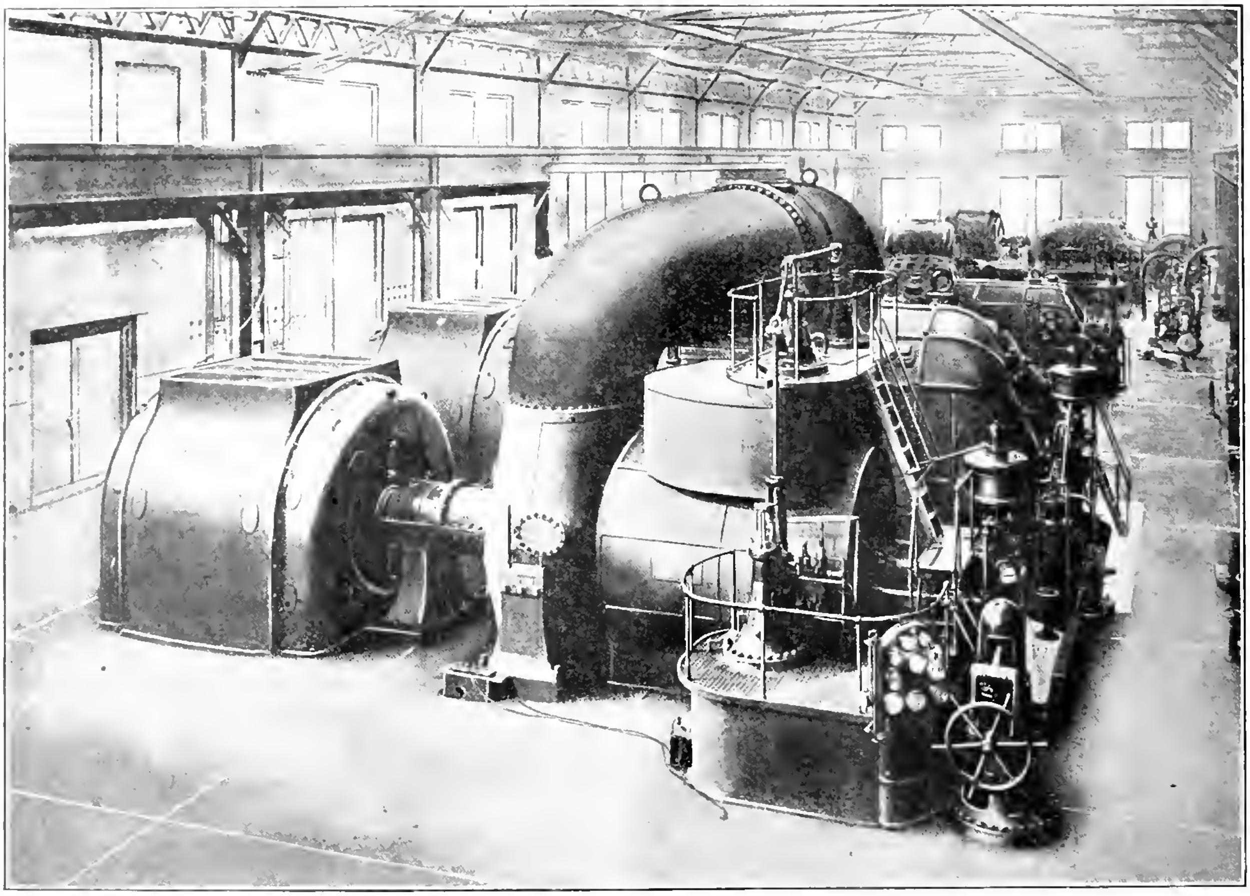

FIG. 4 40,000-KW. CROSS-COMPOUND TURBINE AND GENERATOR, DUQUESNE LIGHT CO. BRUNOT'S ISLAND STATION

ses, and on account of the great import of safety and reliability in these parts, only good quality of plain or 5 per cent nickel low-carbon steels should be used. These are commercially common materials, uniform in quality and do not require sensitive heat treatments.

For rotors cast or forged, steel having a tensile strength of 70,000 lb., true elastic limit of 28,000 to 30,000 lb. and elongation of 18 per cent. in 2 in. may be stressed to 20,000 lb. per sq. in., and for blades, 5 per cent nickel steel having a tensile strength of 85,000 lb., and true elastic limit of 35,000 lb., may be stressed to 25,000 lb., both at 20 per cent overspeed. The stresses at normal operating speed will therefore be 13,900 and 17,350 lb., respectively, and the factor of safety against rupture approximately five.

Increasing the diameter not only permits increasing the blade height, but also the steam speed without materially affecting the efficiency, by reason of the increase in blade speed. There is, however, a slight falling off in efficiency with the higher speeds even though the ratio of blade speed to steam speed be kept practically constant, because the actual velocity of the steam with reference to the blade being greater, the frictional losses will be greater.

The second compromise consists of increasing the steam-passage area through the blades by changing the blade shape. This change increases the angle between the direction of steam flow from the blade and the direction of the blade, and a slight impairment of efficiency results. However, this loss is slight compared to the gain from the higher ratio of blade speed to steam speed resulting from the increased area. This practice is standard on practically all condensing machines built for high vacuum.

Multiple Stages

The third compromise consists of permitting the steam speed to increase without a corresponding increase in blade speed, thereby decreasing the ratio of blade speed to steam speed and increasing the leaving losses. This compromise may properly be employed up to the point where the loss of efficiency will justify the increased expense of greater blade areas which may necessitate dropping to a lower rotative speed, or employing multiple stages.

Two or more low-pressure stages in multiple in connection with a single high-pressure stage are used when the required areas cannot be obtained with a single stage at the rotative speed chosen, and when it is more feasible to employ multiple stages than a lower rotative speed. Other considerations favoring multiple stages are reduced physical dimensions of the exhaust chambers, thus simplifying both the ribbing and bracing necessary to maintain the proper rigidity, and eliminating difficulties incident to shipping large units.

The design of the higher stages usually involves only an equitable selection of diameters, blade speeds, and steam speeds. Keeping these low, results in low stresses and high efficiency, but large number of stages and high cost; while keeping them high reduces the length, weight, and cost, but increases the stresses and impairs the efficiency.

If the steam volumes in the first stages are relatively small for the rotative speed employed, as would be occasioned by the use of high steam pressure or low rating, a double velocity-stage impulse element may often be employed to advantage; the advantages secured being reduction of length, increased diameter, reduced pressure and temperature inside the main cylinder, and adaptability for varying overload capacity, but not increased efficiency nor decreased cost.

Rotor Proportions

Having fixed the rotative speed to secure proper design of the low-pressure stages, and the diameters and steam speeds of the high-pressure stages to give the highest economy, the length of the rotor may become excessive, necessitating its division into two parts in order to maintain requisite reliability. These parts may be arranged either in tandem form, driving a single generator, or in cross-compound form, driving two generators. When arranged cross-compound it will often be found advantageous to increase the rotative speed of the high-pressure element, thus gaining reduced physical dimensions, weight, and cost, without sacrifice of efficiency or reliability. The multi-cylinder construction is especially desirable in the employment of high steam pressures and superheats in that the high-pressure turbine structure is small and there is no danger of stress complications resulting from wide temperature differences and no transmission of heat through the cylinder walls from the high-pressure to low-pressure stages. It has a further advantage in these days of increasing steam conditions since a unit may be designed for given steam conditions and later redesigned for materially higher conditions, the redesign being carried out entirely in the high-pressure element.

In units of 60,000 kw. or larger, the three-cylinder cross-compound construction employing one high-pressure and two low-pressure elements possesses the advantages of high efficiency and reliability without employing excessively large structures, and has greater flexibility than is possible with either of the other constructions. This flexibility, enabling the high-pressure element to operate with either low-pressure element, or either of the three elements to operate alone, admirably adapts it for us in systems not yet large enough to permit employing a single unit of such

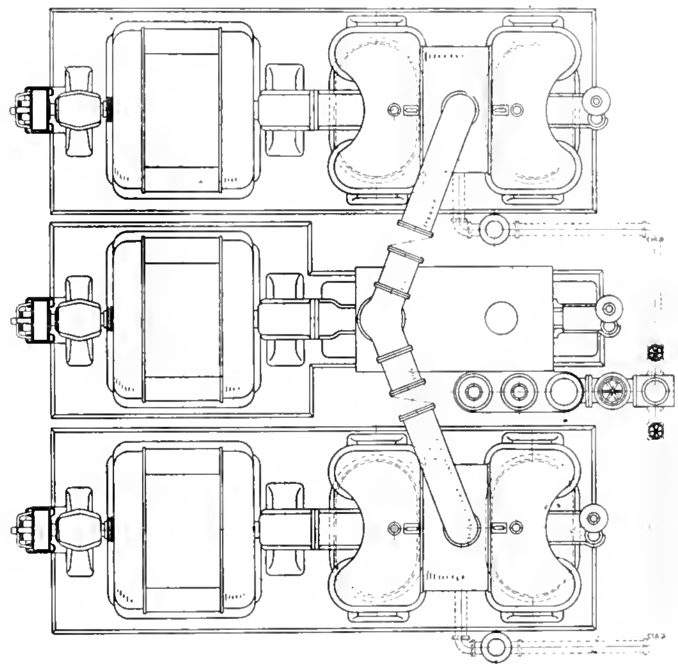

Fig. 5 70,000-Kw. Three-Cylinder Cross-Compound Turbine, Interborough Rapid Transit Co., New York

large capacity. These units may be provided with a control mechanism by means of which either of the elements may be taken out of service either automatically or manually, and the remaining ones carry loads up to the maximum ratings of their generators. The low-pressure elements, when operating on high-pressure steam direct, may be made to carry loads for short periods considerably in excess of the rated capacities of their generators.

Construction Details

Reliability and general operative excellence of a large turbine are largely dependent on the excellence of design of details such as the blading and blade fastenings, provisions for maintenance of clearances and alignment under all possible variations of operating conditions, bearings and oiling system, control mechanism, glands, couplings, and protective devices against overspeeding. The standard practice with regard to these as applied to all large units built by the company with which the writer is connected will be here given.

All low-speed reaction blading in which the stresses do not exceed about 15,000 lb. per sq. in. at 20 per cent overspeed are made of a special bronze composed chiefly of copper and a small percentage of tin and phosphorus. Upon the base of each blade a

foot is forged, and the cross-section of the blade near its base taperingly increased, adding approximately 40 per cent to its area at the point of attachment. These blades are installed in double dovetail grooves by means of specially constructed spacers or interlocking pieces, the spacers being locked in the groove and the feet of the blades locked underneath the spacers. In larger sizes where it becomes difficult to drive up the blades and spacers tight enough to insure perfect fitting between the parts and perfect filling of the grooves, compound side wedges are employed to secure the requisite tightness.

The chief destructive element of all blading is vibration caused by the flow of steam and by vibration of the entire rotor when operated under conditions of defective balance or alignment. The

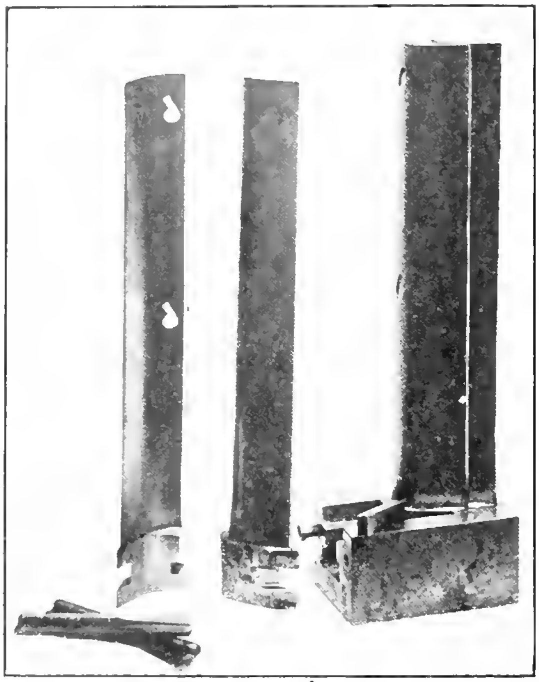

FIG. 6 METHOD OF INSTALLING HIGH-SPEED BLADES

thickening of the blade section near its base serves to very considerably reduce the amplitude of its vibration and to prevent concentration of deflection with its attendant crystallization at the point of attachment, where the ordinary blade is weakest. Blades for higher speeds, in which the stresses may go as high as 25,000 lb. per sq. in., are drop-forged of a very pure electric-furnace iron containing about 5 per cent nickel. They are installed in grooves as shown in Fig. 6.

The spacers are made integral with the blades, and compound side wedges are used to insure a tight fit at the top of the groove and protect the reduced portion of the blade foot against vibrational stresses. Impulse blading when used is installed in the same manner.

All blades are lashed together to minimize the vibration and maintain uniform spacing. Blades up to 4 in. in height have a single lashing near the top, from 4 in. to 12 in. have two, and those above 12 in. three.

A proper design of the turbine stator so as to insure maintenance of clearances and alignment under all possible variations of operating conditions, such as reduction of steam pressure and total or partial loss of superheat or vacuum, is difficult but essential. In such large structures the amount of expansion and contraction due to temperature changes is considerable, and usually occurs simultaneously with important stress changes caused by varying stage pressures, consequently there is no friction of rest to overcome and a comparatively slight uneven temperature change or unbalanced stress will cause a distortion.

The introduction of high vacuum, bringing with it large diameters in the low-pressure stages and enormous exhaust chambers, necessitates a considerable amount of carefully devised ribbing and bracing in order that the bearings supported in the exhaust chamber structures will under all conditions remain concentric with the stationary blade- or nozzle-carrying elements.

Fig. 7 shows such reinforcing. Cast-in braces when employed are always provided with an open joint which is made up after the rough machining and annealing have been done, thus avoiding all distortional stresses.

The main cylinder castings are made as plain, simple and symmetrical as possible, and the blade-carrying elements are almost invariably cast and finished separately.

The turbine cylinder is always supported on the bedplate by means of chairs or pedestals engaging it as near the center line as possible, and independent of temperature changes caused by varying load or operating conditions. The steam chest and throttle valves are supported on springs so as to move freely with the turbine, consequently the alignment of the main turbine and generator bearings is not affected by these changes.

Practically every turbine element contains three bearings; two to support the rotor, and one to maintain the longitudinal alignment. The supporting bearings consist of heavy cast-iron shells lined with babbitt and split horizontally to facilitate removal. They are so bored that for two-thirds of the circumference the minimum clearance between the bearing and journal is approximately 0.020 in., the journal being normally supported and guided by less than the lower third of the bearing circumference. This large clearance reduces to a minimum the power lost and heat generated in the bearing. The journal speed is not allowed to appreciably exceed 100 ft. per sec. and pressure 100 lb. per sq. in. projected area. A sufficient quantity of oil is supplied through

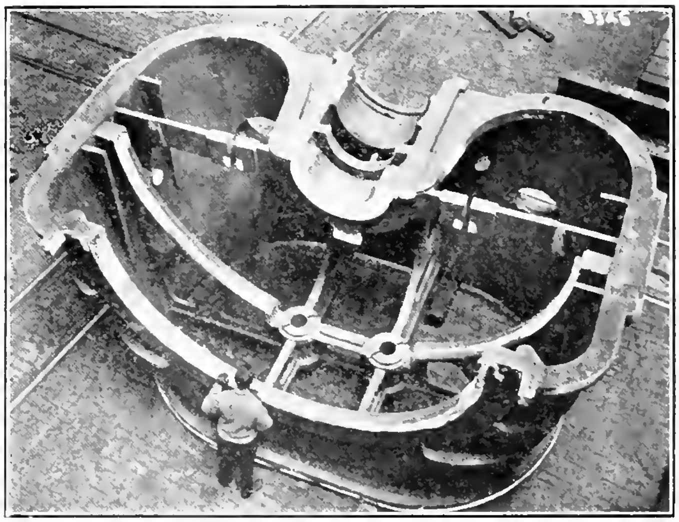

FIG. 7 RIBBING AND BRACING OF LOW-PRESSURE CHAMBER

a longitudinal groove in the top of the bearing to provide both lubrication and cooling; consequently no water cooling of the bearings is necessary. The oil pressure normally carried on the bearings is 5 lb. gage, although they will continue to operate satisfactorily as long as the oil supply is sufficient to keep the oil groove filled without any pressure whatever. The bearing is of course self-aligning, being provided with four large spherically machined pads (one each at the top, bottom and either side), which fit a spherical supporting ring in the housing. Underneath each of the four pads several sheet-steel liners of varying exact thicknesses are placed to enable easy and accurate adjustment of alignment. For example, to change the alignment 0.010 in. either vertically or horizontally a 0.010-in. liner is taken from underneath one pad and placed underneath the opposite one.

The alignment bearing is of the Kingsbury type, modified in detail design to best serve the requirements of the turbine upon which it is employed. This is believed to be the most perfect form of bearing yet devised for the purpose.

The oil-circulating and cooling system maintains an ample supply of oil at approximately 60 lb. pressure for operating the

governor-controlled valve mechanism, in addition to supplying all bearings at approximately 5 lb. pressure. It is designed with special reference to positive circulation, effective cooling, straining, and settling for separation of foreign matter or impurities, accessibility for thorough cleaning and longevity of the lubricating qualities of the oil. It consists of a cooler, strainer box, settling and separating reservoir, direct-driven pump, and a separate steam-driven auxiliary pump, together with the necessary piping. It ordinarily has a capacity of approximately 1000 gal. The oil flows by gravity from the settling reservoir into the oil pump from which it is delivered under 60 lb. pressure to the valve operating mechanism, thence to the oil cooler, bearings, strainers, and back to the reservoir. A spring-loaded valve located close to the valve-operating cylinder by-passes the surplus high-pressure oil direct to the oil cooler. Units in which a considerably greater quantity of oil is required for lubrication than for operating the valve gear are provided with double pressure pumps to reduce the power required, and the stress on the oil. Under normal operating conditions the maximum temperature of the oil is from 140 deg. to 150 deg. fahr.

The oil cooler is built along the lines of an ordinary surface condenser, and employs regular straight condenser tubes. Every part, including the inside and outside surfaces of the tubes, is readily accessible for thorough cleaning so that the original efficiency of the cooler may be restored at every cleaning. The cooling water makes a sufficient number of passes to raise its temperature close to that of the oil so as to decrease the quantity required.

The strainer box contains three strainers of different meshes which may be removed and cleaned while the unit is in service. If they are allowed to become choked up, the oil will overflow them without interrupting the circulation.

The reservoir is designed to cause impurities and foreign matter to settle to the bottom from whence they cannot get into the oil pump suction, but may be drawn off either manually or automatically to a filtration system.

The oil pump is of the reciprocating-plunger type, direct-driven from the main governor spindle, and is accessible for inspection or repairs without complete removal from the turbine.

Since constant voltage and frequency are insisted upon by public-service companies, good governing of a turbine unit becomes important. The governing mechanism must be extremely sensitive, positive, and quick to adjust itself to small or large changes in load and at the same time rugged, reliable, and unaffected by such variations as occur in ordinary wear and care. For these reasons the following several features of design are employed.

On account of the power required to operate the large valves, some form of fluid pressure relay mechanism is necessary. For this the regular turbine lubricating oil under suitable pressure has proven most satisfactory.

The governor, which is of the flyball type, is made very large and powerful so that it can control the oil relay valve with ease and accuracy. It has a minimum number of moving parts and is made as frictionless as possible by the employment of hardened knife-edge bearings in all connections between the weights and clutch. It is driven from the main turbine rotor through worm and wheel gears at a speed of approximately 300 r.p.m.

Unavoidable inaccuracies in machining of the oil relay control valve, friction and lost motion in the governor and valve linkage, and inertia of the operating fluid are the chief obstacles to good regulation, since the speed must change sufficiently to move the governor weights far enough to overcome all these before there will be any response from the valves, and when they do move they will probably overtravel. These difficulties have been overcome by giving the linkage, adjacent to the governor, a small positive oscillating motion, sufficient to overcome any reasonable lost motion and inaccuracy of the relay control valve, and still cause a very slight oscillation of the main inlet valves. The oil relay control valve and high-pressure-oil by-pass valve are placed as close to the operating cylinder as possible, and a positive or constant-volume oil pump is used. The oil flow is therefore continuous in nearly all of the piping to and from the oil-operating cylinder. Consequently the slightest change in speed will be quickly responded to by a proper change in steam flow.

To prevent leakage of steam or air where the rotor shaft passes through the casing, combination labyrinth and water glands are used. These constitute an ideal sealing arrangement. They are absolutely tight and permit no leakage of steam, vapor, or water into the engine room. They require no adjustments for varying load conditions, and do not depend upon the operation of any automatic devices. There is no mechanical contact between stationary and rotating parts, and therefore no wear. They are extremely simple in design, require no special attention, and are as durable as any other part of the machine.

The simple water gland being ill adapted for operation against high pressures or at speeds very much less than normal, the labyrinth is added to enable establishing a vacuum before starting up, and also to reduce the pressure on the water gland when the pressure against which the gland must seal is high. The operation is very simple. In starting up, high-pressure steam is turned on the labyrinth glands. When about three-fourths speed is reached, the water is turned on and the steam off.

The coupling between the turbine and generator is of a flexible-pin type, and has important advantages over the solid-claw type which it replaced. Sufficient elasticity is provided in the pins to distribute the shocks produced by heavy short-circuits and both the pins and bushings are renewable in case excessive wear takes place.

Ratchet teeth are machined into the circumference of the coupling flange, in connection with which a barring-over device is employed to turn the rotor for inspection or for connecting or disconnecting the two halves of the coupling.

In order to secure the maximum protection against overspeeding, all the steam entering the turbine is made to pass through the primary governor-controlled inlet valve; consequently, if this one valve is kept in proper operating condition it is impossible for the speed to get beyond the control of the governor, regardless of whether or not the overload valves leak or stick. Should either the governor or primary inlet valve become inoperative, a small but powerful overspeed stop mechanism installed in the end of the rotor shaft will come into operation at approximately 10 per cent overspeed, and release the pressure on one side of two small steam pistons which normally have full steam pressure on both sides of them. The resulting movement of one of these pistons will release the main spring on the main throttle valve, causing it to close quickly and the other will admit high-pressure oil to the valve operating cylinder, and close if possible the primary inlet valve.

Reports of several disastrous explosions of aluminum dust in manufacturing establishments induced the Bureau of Mines to investigate the physical and chemical properties of the dust with special regard to inflammability and to the problem of extinguishing fires and of minimizing the force of explosions once started. The results of this investigation together with a review of the literature on the subject are published in the Bureau's Technical Paper 152.

It is reported that aluminum dust burns quietly when in a pile, but if this pile be disturbed in such a manner as to raise a cloud of the dust into the air, the burning takes place with explosive violence. Also, that if a dust cloud already formed having a density within the explosive limits be ignited, a violent explosion results. Moisture is said to be most dangerous if the dust has become heated; hence, as the dust is hygroscopic, a proper system of ventilation is strongly recommended as a precautionary measure. It is equally pointed out that if, when the dust starts to burn from whatever cause, water be added to the mass, hydrogen will be liberated and a terrific explosion result. In one case on record a violent explosion resulted from pouring molten aluminum through a screen into a bucket of water.

The tests did not show the exact conditions under which ignition of the aluminum dust is obtained, but it was concluded that it may ignite at temperatures even lower than those necessary for the ignition of 200-mesh standard Pittsburgh coal dust.

Refrigerating Plant Efficiency

By Victor J. Azbe,[1] St. Louis, Mo.

The cost of ice and of refrigeration is a composite figure of many different expenses coming under the heads of manufacturing, selling and general expenses. The cost of fuel is usually the largest item, and it may easily represent the difference between profit and loss.

During the last two years the cost of fuel per ton of ice has doubled, and many plants are now paying $1.50 to $2.00 per ton of ice for fuel alone. In spite of these conditions the majority of refrigerating plants are very wasteful of fuel as a result of improper design, run-down equipment or poor operation. While the possible savings are enormous and can usually be secured with little effort and slight expenditure, the necessity for improving equipment and operating conditions is not realized in the majority of plants.

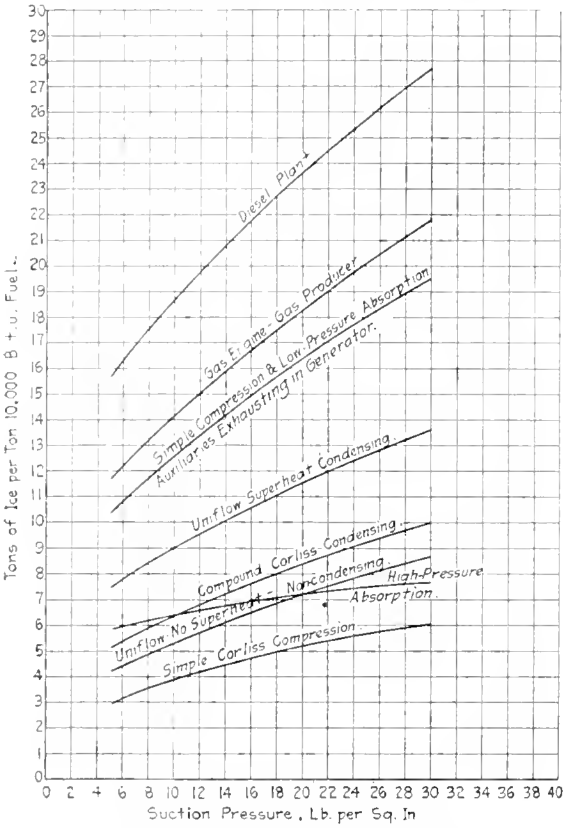

Fig. 1 Relative Efficiency of Various Ice-Plant Installations

It should be the aim to improve the economy of the plants from year to year by making necessary improvements to reduce costs of fuel and labor. Fuel cost, while most important, is not all-important, however, and there are ice plants having a very high fuel economy that are losing money. A high efficiency must be maintained generally in the design of the plant, in its load factor and in its labor and sales organization. There are far more plants making on the average, per year, 1.5 to 2.5 tons of ice per ton of fuel than plants making 5 tons, having simple non-condensing plants in mind.

In this paper the writer expresses himself frequently in terms of tons of ice per ton of 10,000 B.t.u. fuel, to equalize the value of the various fuels (semi-bituminous, bituminous, lignite, oil, etc.), since by a simple recalculation it places them on a common basis.

As the load factor of most refrigerating plants varies greatly, the boiler installation should be such as to give flexibility of operation. In small plants arrangements should be made to reduce the grate surface during the winter periods. Each boiler must be equipped with a draft gage, and the draft should be maintained at the minimum and varied with the load. The boiler setting should be high, even with return tubular boilers, with a space of from 4 to 5 ft. between grate and boiler shell, and the combustion chamber should be so arranged that the benefit of this increased space is obtained. Gases tend to take the shortest path, and with most of the combustion-chamber space devoid of drop walls there will be circulation of the gases and many eddy currents or dead spaces.

Any fuel can be burned if proper provisions are made—shavings as well as oil or semi-bituminous coal. The selection mostly depends upon cost and availability. Lignite, for example, is a most excellent fuel for localities such as Texas. Burning this under return tubular boilers efficiencies were obtained of 63 to 68 per cent.

Prime Movers

The prime mover most generally used in refrigerating plants is the Corliss non-condensing steam engine. Next in order are the compound Corliss, electric motor, oil engine, and uniflow steam engine. If this order were reversed, however, enormous sums of money would be saved to ice manufacturers, for the following reasons:

In selecting the prime mover for an ice plant, the two most important items to consider are efficiency at rated load and efficiency at half load. While the average Corliss non-condensing engine consumes 20 per cent more steam at half load than at full load, the uniflow engine uses only about 8 per cent more. This is of great importance because of the great variations of load factor. Many engines can be found operating at one-eighth cut-off. This is the reason, also, why a steam cylinder should be adapted to the back pressure at which the compressor operates. It is most unwise to have a steam cylinder large enough for economical cut-off at 25 lb. suction pressure when the pressure to be maintained is 15 lb. or less.

Fig. 1 shows the results to be expected from various types of installations. The allowance made for auxiliaries ranges from one-half to one horsepower per ton of ice, depending upon conditions. The condenser pressure was taken at 185 lb. gage, and it was assumed that at the suction pressure given the machine would operate at about full load.

In small plants preference should ordinarily be given to the use of superheated steam, since as high an economy may be obtained from a uniflow non-condensing engine operated with superheated steam as from a compound Corliss condensing engine using saturated steam, and the former equipment is a great deal simpler and necessitates less auxiliary power. Furthermore, the steam-consumption curve is flat and the efficiency of the plant will be maintained during the winter time.

Superheaters can be installed with facility even in existing installations, and since the gain is greater with simple non-condensing engines, uneconomical ice plants will derive great benefit from this procedure.

In order to gain in economy, a simple engine is often made to operate as a condensing engine. As a result, the temperature difference in the cylinder is increased and the cut-off is shortened, which increases the wall area at cut-off as compared to volume. This greatly increases cylinder condensation, which is directly proportional to the temperature difference and the area exposed. It therefore seldom pays to operate such a machine at more than 20 in. of vacuum, and if the plant is to be changed over to condensing operation, it is best to replace the simple Corliss by com-

[1] Consulting Engineer, St. Louis, Mo. Assoc.-Mem.Am.Soc.M.E.

Abstract of paper presented at the Annual Meeting December 1918, of The American Society of Mechanical Engineers.

pound cylinders or by a uniflow engine and leave the rest of the machine intact.

Under proper conditions the ideal and most efficient prime mover for the ice manufacturer is the Diesel oil engine. By "proper conditions" is meant conditions of oil supply and cost, and kind of operating force to be employed. It cannot be overemphasized that with the Diesel engine a high-grade engine-room force must be maintained, and especially during the overhaul period.

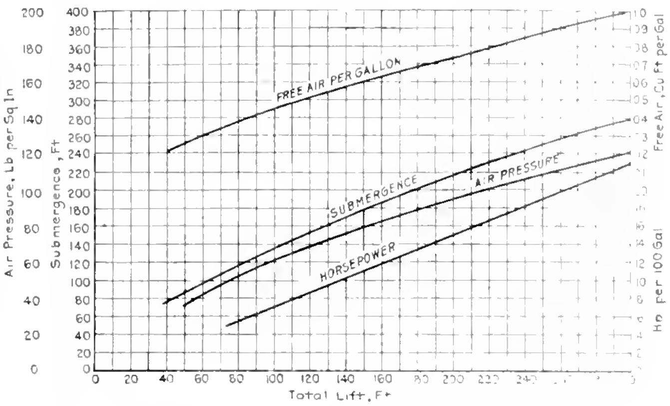

FIG. 2 STANDARD AIR-LIFT PERFORMANCE

If the men in charge are intelligent, the Diesel engine is a very dependable unit. There is a plant in California that produces a ton of ice for 5 gal. of fuel oil, and this not under the best conditions. There are oil-engine installations on record, not necessarily Diesel engines, that have given a ton of ice for less than 10 cents fuel cost, with oil at 2 cents a gallon.

Table 1 gives the average results obtained with Diesel engines over a long period. The net work produced was 1,119,801 kw-hr. The auxiliary power represented the power required for injection in the air compressor, and in the water-jacket circulating pumps. The load factor having been highly variable, the results are not quite as good as they otherwise would have been, consequently the figures may be taken as being conservative and dependable.

In many localities electric power can be obtained cheaply, and when this is the case electric drive is to be favored. The main advantage of an electric installation is that high efficiency can be obtained through the whole load-factor range and that economy increases as the load factor drops, contrary to the condition in ice plants.

Induction motors are not very well adapted for ice-plant work because of the high speeds required for high efficiencies. Synchronous motors, on the other hand, have characteristics that make them ideal, even for direct connection to refrigerating machines. Their efficiency curve is quite flat and their efficiency is rather high at part loads.

An electrically driven raw-water plant is a great deal simpler than a steam-driven plant. Many factors which influence plant efficiency are eliminated, and consequently the operating man does not have to be as high grade as for the efficient operation of steam plants. Labor cost and repair expenses and the cost of real estate, buildings and machinery are all less. Dependability is also fair, and with proper installation as good as in the case of a steam plant.

AUXILIARIES

The curse of most ice plants is the auxiliaries. In many cases the steam consumption of the auxiliaries is as great as that of the

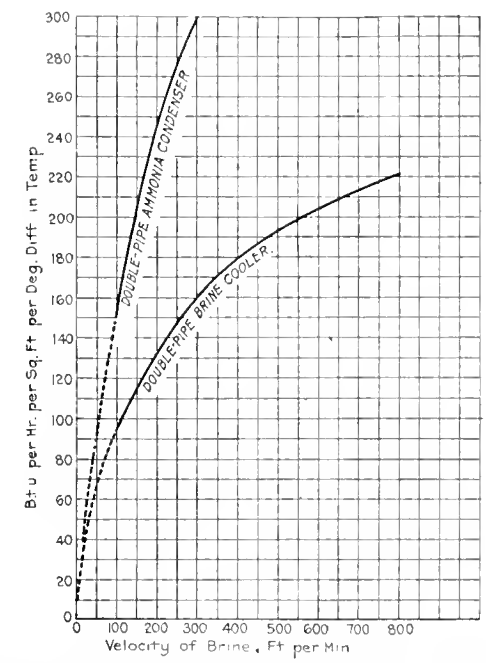

FIG. 3 HEAT TRANSMISSION WITH DOUBLE-PIPE BRINE COOLERS AND AMMONIA CONDENSERS

engine running the compressor. In a certain ice plant of 100 tons capacity the following auxiliaries were found in operation: Electric-light engine; duplex circulating pump for ammonia condenser; duplex circulating pump for steam condenser; duplex brine pump; duplex boiler-feed pump; ice-hoisting compressor; single-stage single-steam-cylinder deep-well compressor; agitator engine and cooling-tower fan engine.

One of the most uneconomical auxiliaries as usually operated is the air lift. This statement is meant as no reflection upon the air-lift pump as such, but on the way in which it is usually operated. Fig. 2 shows the performance of properly designed air lifts; the efficiency decreases somewhat as the lift increases, but should not be less than 60 to 80 per cent, whereas, actually in some cases it will be found as low as 20 per cent; the trouble is usually too great or too little submergence.

It is seldom advisable to use an air-lift pumping system for

the circulation of water over the steam condenser because of the increased head required. The use of a cooling tower is ordinarily to be preferred, and any water needed for make-up may be taken from the air-lift system and passed over the distilled-water and liquid-ammonia coils, thus cooling the latter below the temperature of the circulating water proper.

For driving auxiliaries, electric current from generators driven by uniflow engines it to be preferred in the majority of installations, and the various units must be selected with a view to obtaining a flat efficiency curve between half and full loads; all motors on the larger units should have variable speed control. Duplex steam pumps or steam-driven deep-well pumps should not be used except possibly as a reserve.

Wet versus Dry Compression

Theoretically, dry compression is inferior to wet, both in regard to refrigeration produced per pound of ammonia circulated and the work required for compression. The difference in economy ranges between 6 and 10 per cent, being greater with low suction pressures and high condenser pressures. Practically, however, dry compression is the more economical; that is, it is capable of producing a greater amount of refrigeration per horsepower expended. The reason for this discrepancy is that when wet gas is admitted into the cylinder the liquid is not suspended, but accumulates at the bottom of the cylinder. There it evaporates so slowly during the compression stroke that the evaporation continues after the discharge valve opens, and often even after it again closes when the piston is upon the return stroke, thus causing a certain amount of reëxpansion loss which tends to reduce compressor capacity. Any liquid that evaporates after the discharge valve opens is utterly wasted.

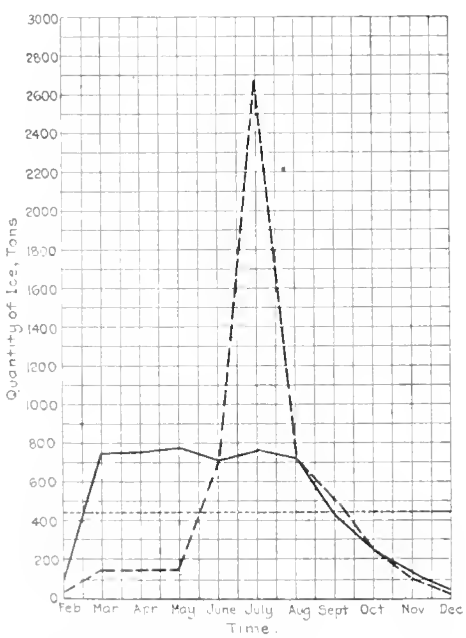

Fig. 4 Effect of Ice Storage on Extreme Load Factor Variations

That there is no benefit in wet compression, as ordinarily practiced, is proven by the compression curve and its relation to the adiabatic and isothermal curves when the machine is operated wet, even to such an extent that the discharge gas leaving the compressor is saturated. In such cases the compression curve will only slightly approach the isothermal, which proves that most of the cooling of the gas by evaporation of the liquid is done after the compression valve opens and thus no benefit accrues from that time on. Liquid and vapor flow separated within the same pipe the same as in the case of saturated steam.

So long as theory indicates an advantage in wet compression, it would seem that further studies and experiments regarding its successful application are justified. Could not some method be devised to atomize the liquid before it reaches the compressing cylinder, or to inject it in the form of a spray during the compression stroke? In any event, precautions must be taken not to introduce liquid into the cylinder in an undivided state, otherwise dangerous accidents are likely to follow.

Wet compression is not only beneficial upon thermodynamic principles, but posesesses a number of other advantages. By its use the temperature difference in the cylinder is reduced by practically two-thirds, which greatly lowers the cylinder superheat and consequently should increase the volumetric efficiency of the machine. Further, with wet compression far less oil is required for lubrication, and the oil does not vaporize, and thus is

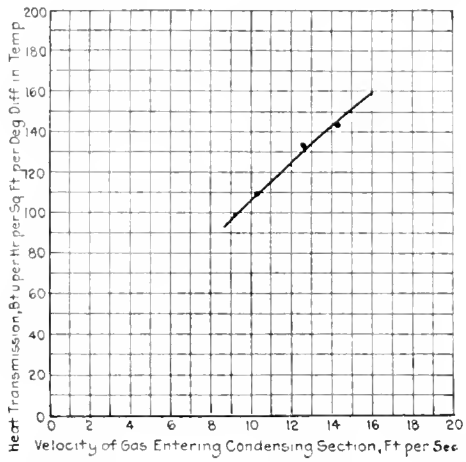

Fig. 5 Effect of Velocity Upon Heat Transmission

easily kept out of the condensing and evaporating coils. Wet compression represents also a saving in ammonia and, in addition, permits a somewhat lower condenser pressure.

Ice Tanks

All the details incidental to the process of ice making should be so regulated as to secure a high rate of heat transmission, coupled with a low temperature difference. The ice tank is a most important member of the ice plant. As far as handling is concerned, great improvement can be made. In a certain plant in St. Louis it was arranged to hoist a row of eighteen 200-lb. blocks by one operation, and the blocks were all thawed and dumped at the same time.

Circulation of the brine in the freezing tank is a very important item. This circulation is at times produced by centrifugal pumps, but ordinarily by propeller agitators. Often these agitators are very inefficient and tend more to churn the brine than to circulate it. It is ordinarily difficult to determine what the circulation in an ice tank is, due to the fact that the speed of the brine varies and its velocity in the lower part of the tank is not the same as in the upper part. About the most practical way is to measure the difference in the height of the brine in the tank on the suction and discharge sides of the bulkhead close to the agitator. With tanks as ordinarily constructed, 1 in. difference of level for each 10 cans of tank length is assumed by the writer as a standard. This method should be fairly accurate since brine flow is the result of difference in level.

In agitating the brine, its level should never be below the level of the water in the can. Too low a brine level will greatly reduce the capacity of the tank and also the plant efficiency. A wide, shallow hole in the top of the block toward the end of the freezing period is always an indication that the can is too full or the brine too low.

Since with long tanks or very strong agitation, considerable brine level difference is produced, in some cases as much as 5 in., it is best to construct long ice tanks with agitators on each end. Brine velocity is helpful in two ways; it increases heat transmission between the brine and the can, and between the evaporating coil and the brine.

The average transmission of heat from the ice in the can to the

brine outside is very poor, only about 2.5 B.t.u. per deg. per hr. per sq. ft., due to the insulating effect of the ice. The thicker the ice, the slower the heat exchange, consequntly tank brine velocity has not nearly so great an effect upon heat transmission on the can side as it has on the coil side. The heat transmission between ammonia and brine through metal is between 10 to 20 B.t.u. per sq. ft. per hr. per deg. This comparatively low figure is primarily due to the superheating of the gas in the coil, which causes one side of the surface to be dry, and secondarily, to the low brine velocity.

Fig. 3 gives York Mfg. Co. curves showing heat transmission with double-pipe brine coolers and ammonia condensers. The curves were extended by dotted lines to show probable transmission at low velocity. These curves purely from their characteristics show the importance of velocity, an item which from the economy standpoint is certainly worthy of very careful investigation.

Ammonia Evaporating Systems

With expansion coils in ice tanks and cold-storage rooms a high heat transmission is very desirable, and it can be obtained

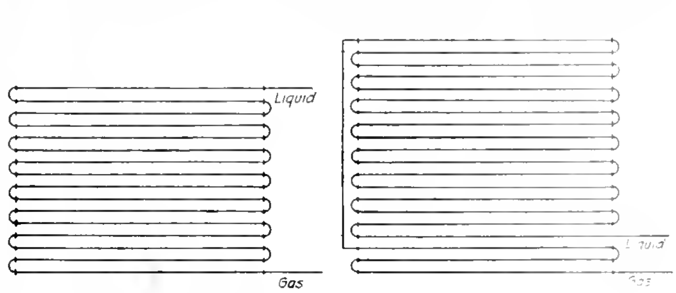

Fig. 6 Ammonia Condenser Types

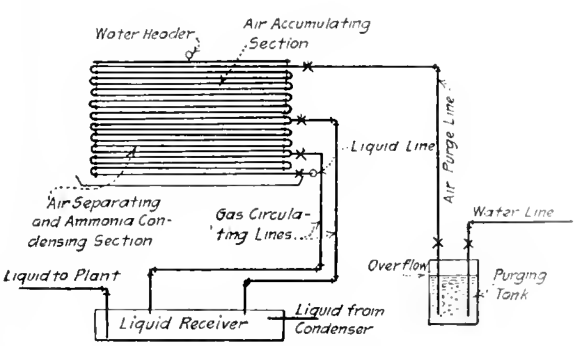

Fig. 7 Non-Condensable Gas-Purging Arrangement

inside of the pipes either by flooding them or using a high gas velocity. The objection to high gas velocity in this connection is pressure drop, which for thermodynamic reasons is rather more important on the evaporating side than on the condensing side. For this reason, the length of the evaporating coil should be limited so that the velocity will never exceed the average figure of 500 ft. per min. Some tank coils are 1500 ft. long and their rather high velocity causes a great pressure drop. For long tanks 2-in. pipe is to be preferred, since the relative surface of $1\frac{1}{4}$-in. and 2-in. pipe is in the ratio of 1 to 1.5, while the sectional area is in the ratio of 1 to 2.2. Coils should be short so that they are thoroughly effective, and even flooded coils should be as short as possible. The size of suction lines leading to the machines should be governed by permissible gas velocity, friction, and radiation loss.

Ice Plant Load Factor—Ice Storage

Ice storage is profitable in most cases if the storehouse is filled to capacity during the winter and emptied entirely in the summer. The cost of storehouse will be from \$6 to \$12 per ton capacity and the investment will net a substantial return in most cases. The objections to it are the cost of refrigeration for the storage and the increased cost of handling the ice.

As far as plant economy goes, the value of ice storage is due to the equalization of the load factor. That is, the plant can be operated at higher rate during slack seasons and there may not be the necessity for forcing the plant beyond its economical limit in summer. The ice plant and ice storage can be so proportioned that the plant will have a load factor of 80 to 90 per cent, while without ice storage it would be only about 40 per cent, taking the whole year into consideration.

The small ice vault, or daily ice storage, exerts also quite an influence upon plant economy and it cannot be overemphasized that it is advantageous to make it amply large. The idea is to remove ice from tanks as quickly as possible—to use ice tanks for storing ice is a very poor practice.

In Fig. 4 the full line represents the output of ice; the broken line indicates the sale of ice, and the dotted line the proper rate of manufacturing ice. These curves were plotted from the figures actually obtained in a plant. An exact determination of the proper rate of manufacturing ice will permit stopping the plant altogether for a certain time and attending to repairs.

To operate with low suction pressure is far less economical than is indicated by the analysis of compressor performance alone, for the reason that the economy of the engine is also affected by the reduction of load. For this reason, when the condenser pressure drops off during the cold season it is doubly important that the suction pressure be increased and the machine maintained fully loaded. The practice of shutting down one or more ice tanks in winter should be strongly condemned, and no tank should be shut off (except in case of absolute necessity) until the back pressure is at the highest point. Efforts should be made to maintain a back pressure of 30 lb. in winter, and the plant should be designed with that in view. The largest loss is occasioned by the non-adjustment of the various elements to the load factor.

The various rooms or tanks in an ice plant should either be maintained at the same temperature or designed especially for low temperatures. To try to maintain one or two rooms at a low temperature and sacrifice the economy of the whole plant is bad practice, since the suction pressure will always correspond to the lowest temperature. The temperatures should be maintained uniform. When this is not possible, and the difference in the various temperatures is great, then either a multiple effect or a booster compressor should be installed.

Forecoolers and Multiple-Effect Receiver

In a well-designed and efficiently operated ice plant the water to be used for ice making is cooled down to within a few degrees of the coldest circulating water, or ordinarily to a temperature of 70 or 80 deg. fahr. This water then passes into the forecooler to be precooled by ammonia. The heat absorbed by the forecooler can be anywhere up to 30 per cent of the total heat to be extracted in making ice, and the water will be cooled down to about 40 deg. fahr. There are two methods of forecooler refrigeration: by feeding liquid ammonia directly into a coil, or by passing wet return gas from the tank through the water cooler. The first has the advantage that it can be connected to a machine working independently from the freezing tank and thus enable the maintenance of very high suction pressure. The only advantage of passing the suction line through the forecooler is that the expansion valves on the tank can be kept open wider, thus insuring that the freezing coils will work throughout their whole length without danger of getting any liquid to the machine. But this same thing can be accomplished far better by means of liquid separators and it is of greater advantage to use the high suction pressure which is possible with direct feeding.

Refrigerating plants should also be equipped with double-pipe liquid precoolers, cooling the liquid from the temperature of the coldest circulating water down to the temperature corresponding to the highest suction pressure used. In this connection a multiple-effect liquid receiver can also be used, by means of which a greater amount of work can be done at high suction pressure than by the use of the double-pipe cooler alone.

Every refrigerating plant should have an auxiliary compressor for high-pressure work. The size of this compressor may be relatively small for the reason that it will operate at double its rated capacity. One of the most valuable inventions ever made in the refrigerating field is the multiple-effect compressor, which allows gas of higher suction pressure to enter the cylinder after it has been filled with gas of a lower pressure.

Ammonia Condenser

There is no reason for a condenser pressure as high as 200 lb. It always indicates improper conditions, and even in a hot climate the condenser pressure should be below 175 lb.

The cooling tower should cool the water within three degrees of the wet bulb. The relative positions of the condenser and cooling tower should be such that five to six gallons of water can be pumped economically; that is, the pressure due to the head should be less than 15 lb. The condenser should give a heat transmission of at least 150 B.t.u. per sq. ft. per hr. per deg. There should also be sufficient surface, and if the condenser gives better results, less than the specified surface will be needed. In actual practice, results ordinarily are far inferior, due to the water being too warm, to the lack of a sufficient amount of water or of the required condensing surface, to the use of a poor type of condenser, or to the presence of oil or air in the condenser or scale on the outside.

The condenser should be located on the roof of the building, with the cooling tower immediately underneath and so placed that the coils will be parallel with the prevailing direction of the wind in the summer.

The cooling of the water over the condensers is important, not only because it simplifies the action of the cooling tower, but also because it produces a greater temperature difference between the wataer and the ammonia and thus lowers the condenser pressure. Theoretically the ideal arrangement would be for the initial and final temperatures of the water to be the same. This is often realized in winter and is also quite possible in summer in a dry climate with good wind velocity and sufficient condenser surface. It is important to protect atmospheric condensers from the sun.

Condensing coils give a much greater heat transmission per degree difference in temperature than evaporating coils. Better results are obtained with the double-pipe condenser than with the atmospheric because of the higher water velocity of the former. Taking into account the question of initial cost, however, an atmospheric condenser, well exposed, should give, for the same expenditure, as good results as the double-pipe condenser.[1]

TABLE 2 AMMONIA CONDENSER PERFORMANCE

No. of test	1	2	3
Type of condenser	A	B	B
Internal surface per stand, sq. ft.	174	222	216
Refrigeration per stand, tons	13.8	5.7	6.5
Surface per ton of refrigeration, sq. ft.	12.6	39	33.2
Water on, deg. fahr.	73	93	84

Entering velocity condensing section, feet per second	6	2.4	2.7
Mean heat transmission per deg., sq. ft. per hr., B.t.u.	155	91.6	26

[1] For articles on Performance of Ammonia Condensers see *A. S. R. E. Journal*, November 1914, and July 1918.

Table 2 gives the results obtained from tests performed upon condenser sets in actual operation. Type A was a counter-current flooded atmospheric condenser. Type B was a condenser installation consisting of ordinary atmospheric condensers with three superheat pipes at the bottom of each stand. The result in Tests 2 and 3 were obtained with type B. When Test 2 was conducted the condenser surface was very clean both inside and outside and the condenser was free from any non-condensable gases; this probably accounts for the favorable performance secured. The values in Test 3 fairly agree with the ordinary performance of condensers similar to B. The writer possesses data of tests performed upon a dozen of these installations, which show practically the same figures.

Fig. 5 presents the effect on the transmission of heat of the velocity of the water in the pipes of a condenser. The points in the graphs were plotted from values obtained with a 12-pipe condenser of the drip-pipe type.

The velocity of the water in the pipes of a double-pipe condenser may be increased by allowing a greater amount of water to flow through them. The gas velocity increases when the height of the stand is increased by the addition of more pipes. In selecting between high and low condensers, however, other factors must be considered in addition to the water or gas velocity. Generally speaking, high condensers are preferable when the available water is cold.

When a condenser is operated with superheated gas, this should not enter at the top of the stand, as is often done in practice. Type B in Fig. 6 is a convenient form of condenser for use with superheated gas.

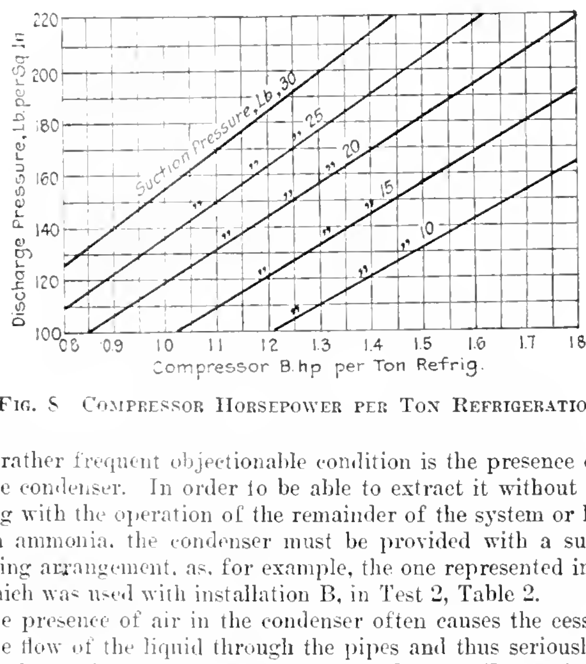

Fig. 8 Compressor Horsepower per Ton Refrigeration

A rather frequent objectionable condition is the presence of air in the condenser. In order to be able to extract it without interfering with the operation of the remainder of the system or losing much ammonia, the condenser must be provided with a suitable purging arrangement, as, for example, the one represented in Fig. 7, which was used with installation B, in Test 2, Table 2.

The presence of air in the condenser often causes the cessation of the flow of the liquid through the pipes and thus seriously impairs the efficient performance of the condenser. The author has had occasion to observe in certain plants he inspected that the condenser pressure dropped 20 to 30 lb. after the air was removed from the system.

Fig. 8 shows distinctly how the compressor horsepower per ton of refrigeration increases with rising condenser pressure, and decreases with rising suction pressure.

Fig. 9 shows how the consumption of condenser water per minute per ton of refrigeration increases as its temperature range over the condenser is decreased, it being assumed that for each ton 350,000 B.t.u. must be removed per 24 hours, inclusive of the heat equivalent of the compressor horsepower.

Cooling Towers and Spray Systems

The economy of a refrigerating plant depends largely upon the temperature of the water circulated in the condenser. Water for ammonia-condensing purposes can be obtained from deep or

surface wells, flowing streams or city distribution systems; or by recirculating water that is being cooled in forced-draft, natural-draft or atmospheric cooling towers or spray cooling systems. Which method is to be preferred depends upon the temperature of the water, the dependability of the supply and the relative pumping level. The cost of pumping water from wells is ordinarily so great that a recooling system is preferred.

The proper construction of a cooling tower is far more important in a refrigerating plant than in a steam plant. In the latter we can get 25 in. of vacuum with water at 105 deg. fahr.; but in the refrigerating plant, with the same temperature, the ammonia condenser pressure would be about 280 lb.

The limit of atmospheric cooling depends upon the wet-bulb temperature. The rate of cooling depends upon the vapor-pressure difference between the dewpoint and the temperature of the cooling water as modified by the wet-bulb depression. Roughly speaking, each degree of water temperature is equivalent to three pounds of condenser pressure.

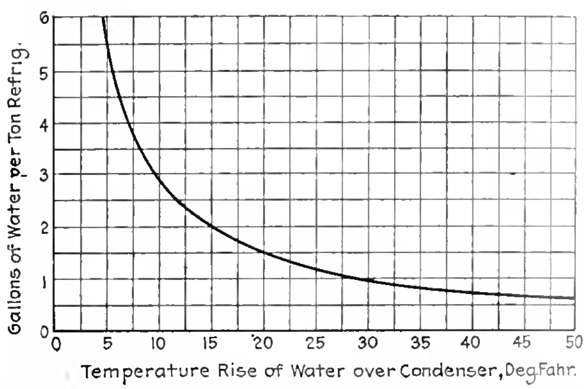

Fig. 9 Temperature Rise of Water Over Condenser with Various Amounts of Water and No Atmospheric Cooling

The use of a properly designed cooling tower is preferable to pumping water from a well, except when the well water is very cold. In summer, in even the hottest and most humid parts of the United States, the temperature of the water in the cooling tower will hardly ever be 85 deg. fahr.; it will ordinarily be below 80 deg. fahr. and in winter 50 deg. fahr. and even less. In fact, with a cooling tower it is not impossible to obtain in winter a condenser pressure of 65 lb., while with well water, the temperature of which keeps more uniform throughout the year, the pressure is higher in winter. The towers should not be built square but rectangular, twice as long as they are wide, and should be placed so that the wind strikes on the longer side.

The proper relative position of the cooling tower, as regards the condenser, is a most important feature. It must be remembered that the auxiliary power should be kept down to the minimum of ½ hp. per ton of ice, also that if the head is reduced more water can be pumped with the same power and thus lower condenser pressures are obtained. In many plants the cooling tower and the condenser are placed on the same level with the result that two circulating pumps are operated in place of one. The relative position of the cooling tower and the condenser should always be one above the other, with the preference of the condenser being in the higher position, since unobstructed air access is more important with an atmospheric condenser than with a cooling tower. Both are more conveniently located upon a roof.

The spray system has recently been introduced in connection with ammonia condensing systems and very good resuls are being obtained. Its cooling efficiency varies from 45 to 70 per cent, depending upon humidity, wind velocity, fineness of spray and pressure at the nozzles. In the calculations which must be made for designing a spray system, however, it is advisable to figure its operating efficiency at 50 per cent. This value has been assumed in the preparation of the curves in Fig. 10, which show the value of the temperature of the water before spraying and the corresponding values after spraying, for various wet-bulb temperatures.

The advantage resulting from the use of a spray system in an ammonia condensing installation is that it reduces the power required, because a spray system does not involve the action of a fan, and a pressure at the nozzle of only six or seven pounds, that is, the equivalent of a tower 14 ft. high is sufficient. Also, the cost of construction and maintenance is less for a spray system than for a cooling tower.

Distilled- and Raw-Water Systems

The advisability of using water evaporators should be carefully considered before adopting a raw-water system in a steam plant. Where the quantity of the available water is such that raw-water ice cannot be made successfully, the installation of evaporators is highly desirable.

There are two types of evaporators, high-pressure and vacuum. Under proper conditions both give satisfactory service and neither one develops as much trouble from the formation of scale as is ordinarily assumed. The writer knows of evaporators operated successfully in a region where the water contains a large amount of salt, a large amount of carbonates, and considerable calcium and magnesium sulphate. Of course, they will have to be cleaned and blown off the same as a boiler, but their use contributes to securing a high economy and simplifies the operation of the plant.

It may be added that a plant short of distilled water is wasteful, as also is the plant that wastes distilled water. A simple steam-driven ice plant should have just enough distilled water to make the ice.

Ammonia Conservation

The chief sources of ammonia loss are blow-outs, careless purging, and leaky stuffing boxes. The first can be prevented by testing the system and keeping up with repairs continuously. Condensers, ice tanks and coils should be frequently inspected, repaired when found deficient, and tested with air of not much above atmospheric temperature. Leaks develop in the stuffing boxes through carelessness in packing them or from the bending of the rod. The only remedy is strict supervision, education of the workmen and the granting of bonuses.

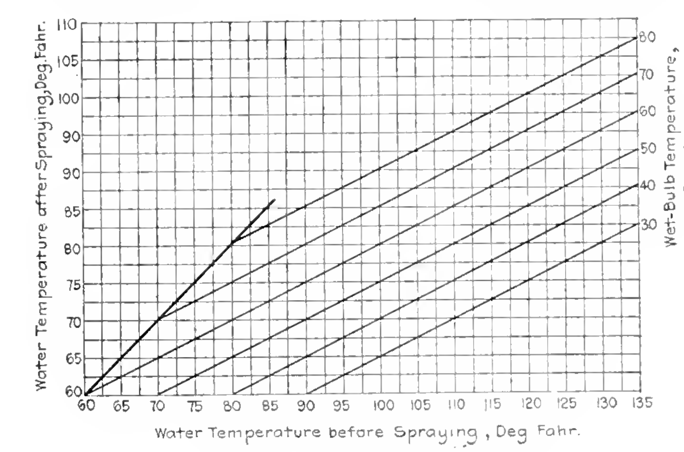

Fig. 10 Performance of Spray System

Bonuses

Bonus systems in ice plants may include bonuses paid for fuel economy, ammonia conservation, quality of ice, quantity produced and service.

The economy and ammonia-consumption bonuses are the most important, but they are defined with difficulty. In regard to economy bonuses, the best system of granting them is devised by taking the quntity of fuel used per tons of ice made in one season as an expected minimum at which no bonuses will be given, and then making a very thorough examination of the plant for the purpose of ascertaining the possibilities of increasing the output. For instance, in an ice plant making 15,000 tons of ice per year

at the rate of 1.5 tons of ice per barrel of oil, a thorough examination proved that with a slight reconstruction and improved operation, 2.3 tons of ice per barrel of oil could be expected; accordingly, Table 6 was drawn up, giving the value of the savings made and the bonus, which was taken as 20 per cent of the saving effected. The monetary value of the saving was based upon the cost of oil, in this case 80 cents per barrel.

The percentage of saving to be paid out as economy bonus will depend upon the size of the plant, the facility of making the saving, the magnitude of saving possible and the cost of fuel, but will range from 50 per cent in small plants to 10 per cent in large plants, or in plants where large savings are possible. Every plant should have an economy standard and the aim should be to do better every year.

TABLE 3 BONUS OUTLINE

Tons of Ice per Bbl. of Oil	Saving, per Cent	Cost of Fuel per Ton Ice, Dollars	Total Saving, Dollars	Bonus, Dollars	Clear Saving, Dollars	Tons of Ice per Ton of 10,000 B.t.u. Fuel
1.5		0.533		...	....	4.8
1.6	6.2	0.50	495	99	396	5.16
1.7	10.9	0.475	870	174	696	5.49
1.8	16.7	0.444	1335	267	1068	5.81
1.9	21.0	0.421	1680	336	1344	6.13
2.0	24.9	0.40	1995	399	1596	6.46
2.1	28.5	0.381	2280	456	1824	6.78
2.2	31.2	0.363	2550	570	2040	7.10
2.3	34.7	0.348	2775	555	2260	7.42
2.4	37.5	0.333	3000	600	2400	7.75
2.5	40.0	0.32	3195	639	2556	8.07

The bonus outline should be simple so the men can understand it, otherwise their interest will be greatly reduced. The bonus should be preferably paid at the end of the season, although this depends upon conditions, and any man leaving the company during the season without a good reason, or any man discharged through fault of his own, should forfeit the bonus.

The ammonia-consumption bonus should not be based only upon the amount of ammonia purchased, but rather upon the amount of ammonia in the system at the beginning and end of the season, as apparent from the liquid receiver plan gage and the amount introduced during the season.

Quantity bonuses are usually granted when the plant is operating above its rated capacity.

Quality bonuses are based on the number of good blocks of ice made, with a deduction equal to two blocks for every poor block turned out.

The service bonus consists of a certain sum which is given to the faithful employees at the end of the season. It can be based upon the earnings of the plant and be thus converted into a profit-sharing bonus; this becomes every day more advisable with the present labor situation and the high cost of operation.

DISCUSSION

Fred Ophuls spoke regarding two-stage ammonia compression. He stated that during the last few years two-stage compression had been used in refrigerating plants where it was desired to cool brine down to 10 or 20 deg. below zero (fahr.). With the higher brine temperatures, 10 to 20 deg. above zero, as used in ice-making plants, the advantage of compound compressors was not so great, and it was still a question whether in this case the increased friction of the two-stage machine did not wipe out the saving derived from compounding. There was, of course, an opportunity in ice-making to cool down the water at a high and favorable intermediate ammonia evaporating pressure, such as 40 lb. gage, but this would not exceed 20 per cent of the total work and should be done in more efficient water coolers than those used heretofore.

Regarding Mr. Azbe's statement that theoretically wet compression was more economical than dry compression, Mr. Ophuls believed the opposite to be true, as would be apparent from a careful analysis of the entropy diagram, as well as from accurately made tests. He said that in wet compression it was necessary to feed extra liquid to the compressor to take up the heat of compression, which meant an increase in volume to be handled by the piston, and therefore an increase in horsepower. He held that dry compression, in which the suction gas reaches the compressor inlet as near its saturation temperature as possible, was the most economical method known today.

Edward N. Trump spoke on the increased steam economy obtained with the uniflow type of engine over the former types in which the initial steam condensation was considerable owing to the fact that the steam on entering came in contact with a relatively cool surface. In the uniflow engine the steam traveled only in one direction, the wall and head temperature was much higher, and therefore the cylinder condensation was almost eliminated, so that a 150-hp. engine non-condensing would use only 18 lb. of steam per i.hp-hr., and condensing, 11 lb. of steam, if the steam was supplied at 125 lb. pressure. Its consumption curve was also very much flatter than with a Corliss engine, and the surface within the cylinder was kept very small. At light load the uniflow engine was therefore nearly as economical per horsepower as at full load. Again, it made very little difference in the total heat consumption whether the steam was highly superheated or dry saturated.

Halbert P. Hill[1] spoke in favor of the electrically operated ice plant, driven by a constant-speed synchronous motor direct-connected to the ammonia compressor. He said such motors were now obtainable for speeds as low as 50 r.p.m. without excessive cost, and that their efficiency was higher than with any other type.

George A. Horne also was in favor of electric drive, because it was mutually advantageous to both the user and the central station. The central stations had to maintain large equipments to take care of peak loads during the winter. Ice and refrigerating plants required most of their power in summer. For a number of years the central stations in large cities had offered to such plants "off-peak" contracts at attractive rates. This off-peak period might extend over two to four months in winter, during which time the customer agreed to use from 4 to 8 p.m. not to exceed 20 per cent of the preceding maximum demand. Any current used in excess of this must be paid for at a high rate, but with judicious management this penalty did not arise. In fact, it was found in two 500-ton plants that the shutting down of the main compressors for four hours was hardly noticeable in well-insulated cold-storage rooms filled with chilled goods, and even in a pipe-line system there was so much reserve capacity stored up that the heat influx during such idle time could be easily removed when the machines were started at 8 p.m. In other words, an interruption of 4 hours out of 24 proved to be entirely practical, so long as the auxiliaries were kept going, and thus large ice and refrigerating plants were in position to secure a rate as low as 0.9 cent per kw-hr.

An interesting utilization of the energy available in the steam jets emitted from the soil in volcanic regions is found at Larderello, Italy, where a central plant of 16,000 hp. is operated continuously and distributes current to Florence, Livorno and Grosseto.

The Larderello region is extensively covered with volcanic formations, the most wonderful being the so-called "soffioni," which are certain volcanic vents emitting powerful jets of very hot steam. By boring holes, powerful jets at a pressure of two to three atmospheres have been obtained. The first utilization of this steam was made in 1905 when the steam ejected at the Nenella fissure was applied to a 40-hp. engine. Later in 1912 satisfactory results were obtained with a 300-hp. turbo-alternator. The subsequent increase in the price of coal, especially during the years of the war, has stimulated the exploitation of the thermic energy of these soffioni on a much larger scale. As other substances are emitted with the steam, among them sulphuric acid, the steam from the soffioni is used only for heating. Three turbo-alternators of 3000 kw. each are supplied with low-pressure steam from boilers heated by the natural steam which is piped and carried to them.

ECONOMICAL SECTION OF WATER CONDUIT FOR POWER DEVELOPMENT

By CARY T. HUTCHINSON,[1] NEW YORK, N. Y.

THE literature of water-power engineering accessible to the writer does not include a discussion of the method of determining the economical section of a water conduit for supplying water to a power plant.

In what follows a formula for the best slope and size of conduit is deduced, which takes into account in a practical manner the construction costs, the value of the power recovered, and the rate of returns expected on expenditures made, as well as the other physical conditions of the problem. The resulting relation between the best area and the quantity of water is shown in Fig. 2, for chosen values of factors entering the problem, and it is pointed out how, by a simple modification of the graphs of this figure, the relation for other costs and unit prices can be easily determined. One interesting result is that for a flume, or for any conduit, for which the increment cost for increasing the capacity by a relatively small amount is proportional to the surface, the best speed of flow of the water is constant, independent of the size of the conduit.

The economical section is evidently that resulting in the greatest net earnings of the power plant under the conditions controlling the market where the power is delivered. Inasmuch, however, as this section must be determined in advance of complete knowledge of market conditions, it is clear that only an approximation can be made, and that a ready method to determine the variation in net earnings for a large range of sections and shapes of water conduit may be useful.

Assuming that a certain shape and slope of water conduit is fixed upon provisionally, the question is whether some change either in the slope or in the shape or size of the section will result in an increase in net earnings. Any increase in the dimensions of the conduit will obviously entail an increase in construction cost, and hence an increase in annual charges. This increase in annual charges is limited, practically speaking, to interest, amortization and profit, inasmuch as only small changes in a quantity which itself is a small part of the total are under consideration. For instance, under ordinary conditions the loss in the water conduit may vary from, say, 5 per cent to 10 per cent of the total power; it is a variation of possibly 25 per cent one way or the other in this 5 per cent or 10 per cent that is involved.

It is therefore evident that no increase in operating charges, or maintenance, or repairs need be considered, and that the changes in design of the conduit should carry charges only for interest, amortization, and profit. An allowance for profit on the additional expenditure must be included, since every dollar invested should earn its share of profit as well as its fixed charges.

The increase in power resulting from an increase in the size of the conduit brings in a certain addition to gross earnings. Against this, in theory, should be charged the costs of operation and maintenance on the additional equipment and machinery required to deliver this power to the market; but for the same reasons stated in considering the water conduit, all these charges against the additional gross earnings may be ignored in this analysis, as they are negligible in amount, due to the fact that the increase in the power output is small. There would, in fact, be no increase in operating charges, and under practical conditions there would be no increase in equipment, and therefore no increase in fixed charges on equipment.

The matter then reduces to the comparison of the additional gross earnings from the power recovered by an increase in the size of the conduit on the one hand, and the additional interest, amortization, and profit on the cost of the enlargement of the conduit on the other.

The determination of additional power is simple, involving merely the overall efficiency from the water to point of delivery. A consideration of the value of this increased power is a matter of judgment on the part of the engineers and executives of the enterprise, giving attention to the market conditions under which the power is sold, and particularly to the load factor.

The determination of the additional cost of the conduit, however, is more difficult, inasmuch as this cost depends in theory not only on the area of the cross-section of the conduit, but also upon its shape; that is, upon the hydraulic radius or the wetted perimeter. The relation between the area and the wetted perimeter differs, for example, for a rectangular, a circular or a hexagonal conduit, and cannot be expressed in a simple equation to cover all shapes of conduit. The practical way to handle the problem is to fix upon one shape of conduit, determine the economical area and slope for this shape, and then follow out a similar procedure for such other shapes as may be practicable in the case under consideration. This determination being made for the several possible shapes, the best result is then selected.

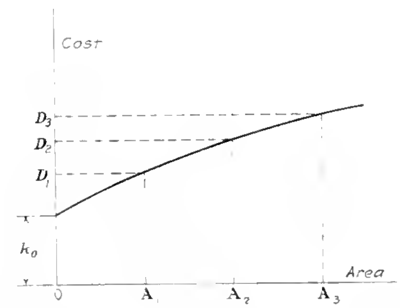

FIG. 1 RELATION BETWEEN SECTIONAL AREA OF CONDUIT AND COST

The procedure indicated in the foregoing general discussion can be expressed symbolically as follows:

Let Q = flow in sec-ft., taken as constant
L = length of conduit, ft.
A = area of conduit, sq. ft.
s = slope of conduit, ft. per ft. of length
r = hydraulic radius of conduit, ft.
w = wetted perimeter of conduit, ft.
v = speed of flow, ft. per sec.
C = constant in the Chézy formula
e = efficiency from water to point of delivery $\times$ 0.085.

Then the power loss p in the conduit in kilowatts will be

$$p = eQsL \qquad [1]$$

In this equation s is the variable, and any change of p is due to a change of s and is expressed by

$$dp = eQLds \qquad [2]$$

If m is the annual value of one kilowatt under the ruling conditions, then

$$mdp = meQLds \qquad [3]$$

is the added gross (and net) earnings due to the change in s.

As to the cost of increasing the capacity of the conduit, the flow is assumed to be given by the Chézy formula

$$v = \frac{Q}{A} = C(rs)^{0.5} \qquad [4]$$

The best size of conduit is to be determined for a known value of the flow Q; that is, in Equation [4] Q is to be taken as constant. In this case,

$$\frac{dQ}{ds} = 0$$

and

$$\frac{dA}{ds} = -\frac{2}{5}\frac{A}{s}; \quad \frac{dw}{ds} = -\frac{1}{5}\frac{w}{s}; \quad \frac{dr}{ds} = -\frac{1}{5}\frac{r}{s} \qquad [5]$$

[1] Consulting Engineer. Mem. Am. Soc. M. E.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

With Q constant, a change in s can be offset by a change in either A or r, or in both: that is, either the size or the shape of the conduit can be varied to keep Q constant.

There is no way of expressing a general relation between A and r, but for any chosen shape, as, for example, a rectangle or semicircle, the area is proportional to the square of any linear dimension: that is,

$$A = ar^2 = wr = \frac{w^2}{a} \ldots\ldots\ldots\ldots\ldots\ldots [6]$$

The value of a, of course, varies, but for usual forms the differences are not great, and the influence of changes in a on the economical section is slight; in fact, it can be shown that for the best section

$$A \propto a \; [illegible]$$

for the conditions of Equation [7a]. Table 1 gives values of a

TABLE 1 VALUES OF SECTION CONSTANT a FOR VARIOUS SECTIONS

Shape of Section	Hydraulic Radius	Cross-Section	Section Constant a	Section Constant $\sqrt{a}$
Semicircle, radius $=r$	$r/2$	$\pi r^2/2$	2π	2.51
Square, side $=d$	$d/3$	d^2	9	3.00
Half-square, depth $=d$	$d/2$	$2d^2$	8	2.83
Hexagon, half-full, depth $=d$ 	$d/2$	$\sqrt{3}d^2$	$4\sqrt{3}$	2.55
Prism: 				
Tan $\alpha = 1/1.5$, $b = 4d$	$0.72d$	$5.5d^2$	10.6	3.26
Tan $\alpha = 1/2$, $b = 10d$	$0.83d$	$12d^2$	16.0	4.00

for the usual shapes. For preliminary calculations $a = 9$ may be used.

The cost of a water conduit can be expressed as a constant, representing the cost of a large part of the preliminary work and plant, plus an amount depending on the size and surface area. In general, the cost per foot may be expressed by

$$D = k_0 + kA^n \ldots\ldots\ldots\ldots\ldots\ldots [7]$$

where D = cost per foot, dollars
k_0 = constant part of cost per foot
k = a constant
n = an exponent whose value lies between 1 and 0.5.

In any specific case, when all the conditions are known, estimates of the total cost per foot of the conduit should be made for three or more different cross-sections; plotting these values will enable both k and n to be determined.

For example, let Fig. 1 represent the cost per foot for a certain conduit; then k_0 is given at once by the curve, and from

$$\frac{D_2 - k_0}{D_1 - k_0} = \left(\frac{A_2}{A_1}\right)^n$$

n is determined. Each pair of points should be used and the value of n found. The values of n and k_0 being known, k may be obtained from

$$k = \frac{D_1 - k_0}{A^n}$$

Other methods could be used. The gist of the matter is that the accurate way is to make detailed estimates for several cross-sections and determine the constants from an analysis of these estimates.

Two extreme cases simplify the formula: First, when the increment cost is proportional to the area, as in a heavy rock cut, then

$$D = k_0 + kA \ldots\ldots\ldots\ldots\ldots\ldots [7a]$$

and, second, where the increment cost is proportional to the surface, or the wetted perimeter, as for a flume, then

$$D = k_0 + kA^{0.5} \ldots\ldots\ldots\ldots\ldots [7b]$$

These are considered later.

If i represents the total rate of returns expected on all expenditures on the property, including interest, amortization and profit, then

$$I = iL(k_0 + kA^n) \ldots\ldots\ldots\ldots\ldots\ldots [8]$$

gives the total returns from this investment, and a change ds in s calls for a change in returns of

$$dI = niLkA^{n-1}\frac{dA}{ds}\,ds \ldots\ldots\ldots\ldots\ldots [9]$$

or, from Equation [5],

$$dI = -\frac{2niLkA^n}{5s}\,ds \ldots\ldots\ldots\ldots\ldots [10]$$

This saving, due to an increase in s, must be at least equal in value to the power lost, and indeed should exceed it by some margin; this margin can be included in the overall rate of return i, and therefore

$$dI = mdp \ldots\ldots\ldots\ldots\ldots\ldots [11]$$

Substituting in [11] from [10] and [3], there results

$$5meQs = 2kniA^n$$

Substituting further from [6] and [4], namely,

$$s = \frac{v^2}{C^2 r} = \frac{v^2}{C^2(A/a)^{0.5}}, \text{ and } Q = Av,$$

gives finally

$$A^{n-0.5} = \frac{2.5mea^{0.5}}{nikC^2}\,v^3 \ldots\ldots\ldots\ldots\ldots [12]$$

This may also be written

$$A^{(n+2.5)} = \frac{2.5mea^{0.5}}{nikC^2}\,Q^3 \ldots\ldots\ldots\ldots\ldots [13]$$

If

$$N = \frac{2.5mea^{0.5}}{nikC^2} \ldots\ldots\ldots\ldots\ldots\ldots [14]$$

then

$$A^{(n+2.5)} = NQ^3 \ldots\ldots\ldots\ldots\ldots\ldots [15]$$

The best way to handle this equation for engineers is by logarithmic plotting. From [15]

$$\log A = \frac{\log N}{(n+2.5)} + \frac{3}{(n+2.5)}\log Q \ldots\ldots\ldots [16]$$

When n is known, this can be readily plotted for any range of Q desired. As an illustration, assume:

$$m = \$10,\ e = 0.67 \times 0.085 = 0.057$$
$$i = 0.15, \quad C = 120$$

then

$$N = \frac{10^{-3} \times 2}{nk}$$

If, further, $n = 0.75$ and $k = \$0.10$,

$$N = 10^{-2} \times 2.67$$

and

$$\log A = \frac{\log 10^{-2} \times 2.67}{3.25} + 0.925 \log Q$$
$$= -0.485 + 0.925 \log Q \ldots\ldots\ldots\ldots\ldots [18]$$

Fig. 2 is the logarithmic graph of Equation [18] for values of Q from 100 to 10,000, in four parts; for the line BC the ordinates are to be multiplied by 10 and the abscissæ by 100; for CD, by 100 and 100; for DE, by 100 and 1000; for EF by 1000 and 1000—all as indicated by the figure. From this figure, Table 2 is readily computed.

TABLE 2 VALUES COMPUTED FROM FIG. 2

Q	A	V	r	s (Ft. per 1000)
100	23	4.35	1.60	0.830
500	100	5.00	3.34	0.520
1,000	191	5.22	10.50	0.180
2,500	450	5.56	16.70	0.128
10,000	1,650	6.08	33.30	0.077

Two special cases are of particular interest: First, when $n = 0.5$ and the increment cost is proportional to the surface; this would approximate the case of a flume or a concrete-lined canal in earth. Here

$$A^3 = NQ^3$$

and, since $v = Q/A$,

$$v^3 = \frac{1}{N} \dots\dots\dots\dots [19]$$

or there is one best speed of flow independent of the size of conduit. This is a somewhat surprising result.

The second case is when the increment cost is proportional to the amount of excavation, as for a costly rock cut: here $n = 1.0$, and

$$A^{3.5} = NQ^3 \dots\dots\dots\dots [20]$$

This can be solved either by plotting, as in Fig. 2, or as follows:

$$A^{0.5} = Nv^3 \dots\dots\dots\dots [21]$$

and

$$Q = Av$$

Calculate $A^{0.5}$ and A from [21], assuming values for v; then find Q, which can be plotted to A.

Variations in A resulting from other values of the unit costs than those used in plotting Fig. 2 can be easily taken into account without replotting these curves. Put

$$N^1 = fN$$

then

$$\log N' = \log f + \log N$$

and a length equal to $\log f/(n + 2.5)$ added to the ordinate of the curve at any point will give the value of Y for $N' = fN$. If f is less than unity the length is to be subtracted. For example, for the point P of Fig. 2, $Q = 2500$, $A = 450$, $v = 5.56$. If $f = 1.5$, then P_1 is the point where $PP_1 = \frac{\log 1.5}{n + 2.5} = \frac{\log 1.5}{3.25}$. If $f = 1/1.5$, P_2 is the point. These values are given in Table 3.

TABLE 3

N	Q	A	v
$10^2 \times 4.00$	2500	510	4.90
$10^2 \times 2.67$	2500	450	5.56
$10^2 \times 1.78$	2500	395	6.32

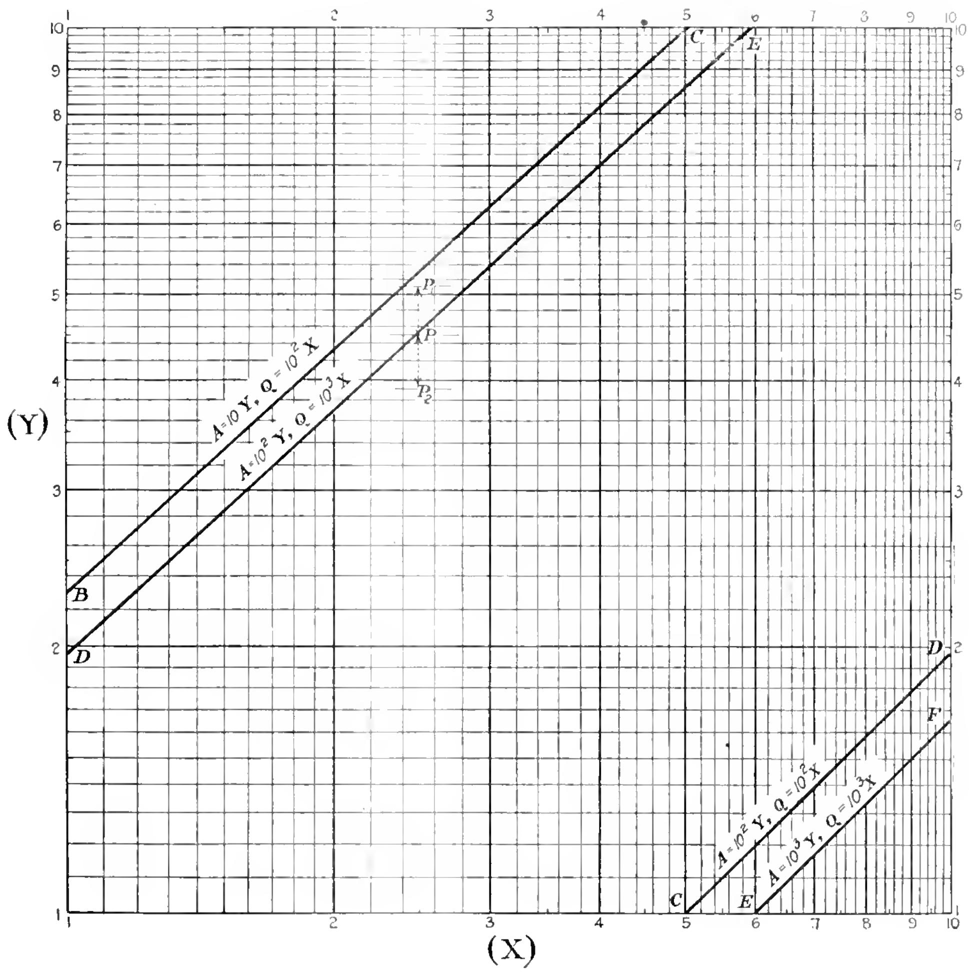

FIG. 2 LOGARITHMIC GRAPH OF EQUATION [18] FOR VALUES OF Q FROM 100 TO 10,000 SEC-FT.

The usefulness of this analysis is limited by the accuracy of the determination of n, and this in turn depends upon the definite knowledge of construction costs.

Natural gas, valued conservatively at $9,000,000, was wasted in a year in a group of Kansas and Missouri cities and towns, according to figures just gathered by the United States Fuel Administration. These figures show wastes varying from 27 to 73 per cent of the gas delivered to the gates of the cities and towns. The main cause of this great wastage is leakage due to poor construction of pipe lines.

To prevent further waste and to determine whether the fault lies with the wholesale or the distributing companies, arrangements have been made to have all wholesale meters in the affected district checked by the Division of Weights and Measures of the Bureau of Standards.

The figures of the Fuel Administration were obtained from the statistics of the wholesale companies as to the number of cubic feet of gas delivered to the gates of the cities and from the figures shown by the meters of the domestic consumers, the difference being the waste. (*Official Bulletin*, Jan. 6, 1918, p. 7)

Engineering Achievements of the Army

AMERICAN Engineers will always be remembered as the "Fighting Engineers," and yet their professional achievements during the Great War are also cause for just pride, for success has invariably attended their endeavors. During the war it is obvious that nothing could be learned of their work, but now that the struggle is over, publicity is quite proper, and an exhibition at which many war devices were shown for the first time was accordingly held at Washington, D. C., on February 21, 1919, under the direction of General Black, Chief of Engineers, U. S. A.

Before describing the various exhibits it may be well to state that the Engineering Department is charged with a great variety of duties. Throughout the war this Department not only organized and trained its own troops but also purchased, stored and supplied engineering material and equipment of every conceivable kind. The organization of the Department was also such that it could control production to meet its particular needs in the field, and early in the war, therefore, the Department found itself actively engaged in engineering research and development of new equipment.

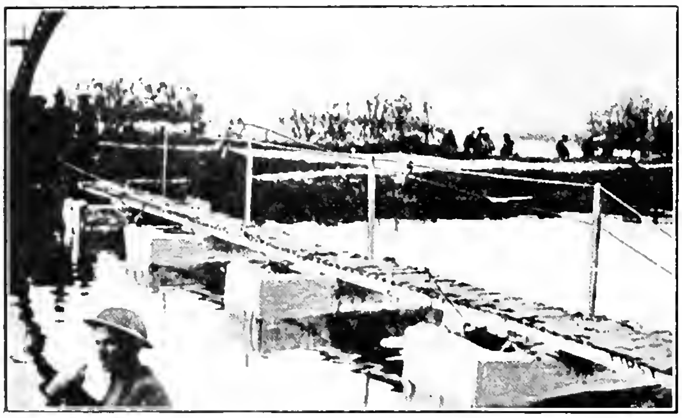

Fig. 1 Portable Foot Bridge

To carry on their work the Engineers rapidly grew from 1.6 per cent of the total army at the beginning of the war to 10.8 per cent at the end, increasing 131½ times their original size, whereas the entire army increased only 19½ times. This tremendous growth naturally demanded considerable tonnage to maintain oversea troops and it is therefore not surprising to find that at the end of the war the engineers were using 27 per cent of all shipping to France.

Railroads

One of the first difficulties encountered by the A. E. F. was the transportation of troops and supplies from French seaports to front-line trenches. The solution of this problem was shown in an interesting exhibit of photographs. Both narrow- and standard-gage equipment were shipped overseas as rapidly as tonnage could be obtained, the latter being supplied in enormous quantities.

Locomotives, tenders and cars, usually 35 at a time, were loaded completely assembled into ships. In this manner over 1300 locomotives were shipped to France and a great saving in labor, time and money thus resulted. In this connection it is of interest to note that the Atchison railroad which operates 1400 miles of track in France has but 1000 standard-gage locomotives.

The number of cars sent abroad, if placed end to end, would extend 140 miles, and if the armistice had not been signed there would have been by July next 682 miles of cars alone.

That the cost of railroad equipment could be lowered in war time seems incredible, but by adopting American manufacturing methods locomotives which were costing the French $51,000 were obtained, even at a time when the price of material was rising, for $37,000.

The narrow-gage railroad proved of great value, especially near the front, because the tracks could be more easily and quickly repaired than roads, and in addition the cost of transportation was only about one-seventh that of haulage by trucks.

Bridges

An exhibit which invited special attention was a collection of photographs showing several types of portable and pontoon bridges designed especially to support heavy loads occasioned by the introduction of the tank and heavy mobile artillery.

Portable steel bridges were manufactured in sections 10 ft. long. They are designed so as to be rapidly bolted together and thus could easily be transported on trucks; and because they can carry loads as high as 30 tons, even tanks could be driven over them. They were used extensively along the fighting fronts, as the forces advanced, to replace bridges that had been destroyed by the enemy.

The construction of the ordinary pontoon bridge was also so modified that in place of the usual loads of 3½ tons per axle the bridges were able to support a load of 15 tons per axle and in addition 30 men. These bridges can easily carry the heaviest mobile artillery, and a raft is now being developed from pontoon material which it is expected will carry the famous 30-ton tank.

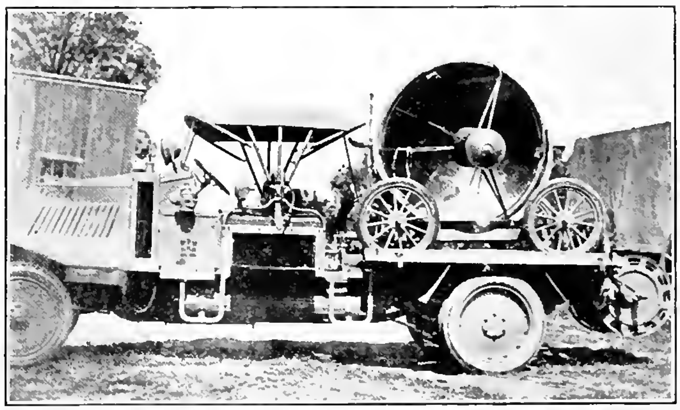

Fig. 2 60-in. Portable Searchlight on Truck ready for Transportation

Not all the design and development work was done in this country, however, for one of the most valuable bridges was a light foot type, designed and perfected by an engineer officer in France. This bridge is supported on boats made of canvas stretched on wooden frames. Duckboards form the floor. A single truck can carry 285 ft. of this bridge and it can be erected by a few men in a very short time.

In the crossing of the Meuse and the taking of the heavily fortified heights on the east of the river these bridges proved invaluable. In some cases they were put up under heavy fire, and the bridge which was thrown across the Canal de l'Est near Dun-sur-Meuse (Fig. 1) was under machine-gun and shell fire 26 hours before the infantry could cross.

Searchlights

As an example of American method of development an exhibit of searchlights showed what could be accomplished even in a short time.

At the opening of the war the Army-type searchlight had been developed only for battlefield illumination and seacoast defense. The best-known type of such lights was the 60-in. seacoast model which weighed 7500 lb. and cost approximately $10,000. By the

elimination of heavy fittings and the protecting glass doors in front and substituting Ford wheels and axles for the cumbersome old type of mounting, an equally powerful light was obtained which costs, however, but two-fifths as much, weighs but 900 lb. and can be much more rapidly manufactured. This new light is known as the portable open type, and Fig. 2 shows how easily it can be transported.

In connection with the development of these lights the subject of mirrors naturally arose, with the result that metal mirrors will perhaps soon replace all glass ones. It was found that the glass mirrors required considerable time to manufacture, and that only one firm in the United States was properly equipped to do the work. Research was at once started and metal mirrors were soon being manufactured at a cost one-third that of glass. The process is an interesting one, and is briefly as follows:

The glass portion of a mirror is first made in the usual way. This glass first receives a silver coating, and next metal is deposited on the silvered surface. When the deposit has reached the required thickness of about $^3/_8$ in. the glass is pried from the metal. Thus the glass is used only as a form, and the process can be easily repeated. Unskilled labor, it is stated, can produce very satisfactory mirrors and an adequate supply was thus assured.

These mirrors have given very satisfactory results. They run cold even when used in lights carrying from 400 to 500 amperes, and their freedom from all ordinary accidents to which glass mirrors are subject makes them very popular.

Map Production

The demand for maps of all kinds was tremendous, as military operations could not be successfully carried out unless charts were available in large quantities. An exhibit of a portable map-reproducing set which went with each division disclosed the fact that American engineers could turn out 1,300,000 maps every 24 hours. The United States Engineers' map-reproduction plant in France was said to be larger than any similar plant used by the Allies.

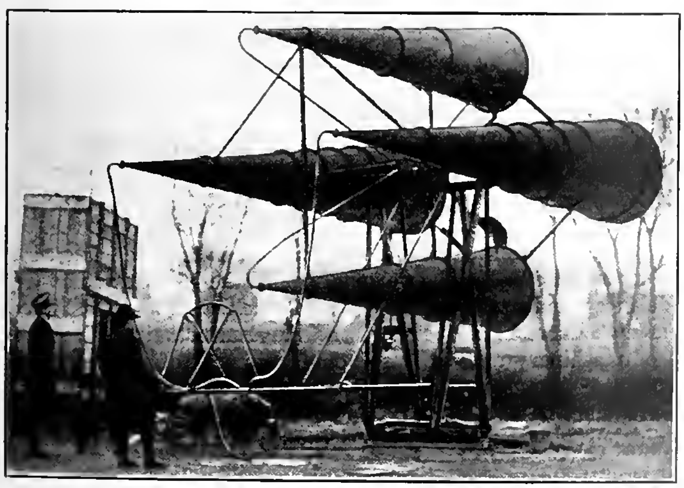

Fig. 3 Long-Horn Listening Device for Locating Enemy Aircraft

Lithographic machinery on portable truck bodies, which could be lifted from the truck and placed on the ground, thus releasing the truck for other service, were also available, and the 29th Engineers had as part of their equipment machinery of this type whose capacity was greater than that of the permanent Geological Survey map-reproduction plant in Washington.

Map production from aerial photographs was made possible by the Bagley cartograph. This machine takes three pictures at a time from an airplane, mapping a strip 3 miles long and $\frac{1}{2}$ mile wide at an elevation of 4000 ft. The pictures can be easily matched together, and an exceedingly accurate map is thus obtained.

Forestry Operations

As illustrating still another field in which the engineers were engaged, one exhibit treated of lumbering in France. In one month alone 50 million board feet of sawed lumber was produced, a pile 10 ft. high, 12 ft. wide and 6.6 miles long. Eighty thousand cords of wood were also cut, and this if piled 4 ft. high and 8 ft. wide would extend 60 miles. In addition standard-gage railway ties were produced sufficient to build a single-track road 1091 miles long.

Camouflage

Camouflage in all its various forms has been treated of time

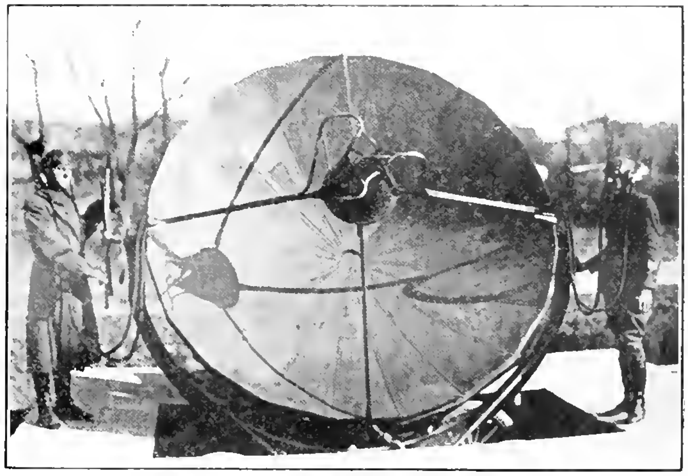

Fig. 4 American Paraboloid—A Development of the Long-Horn Set

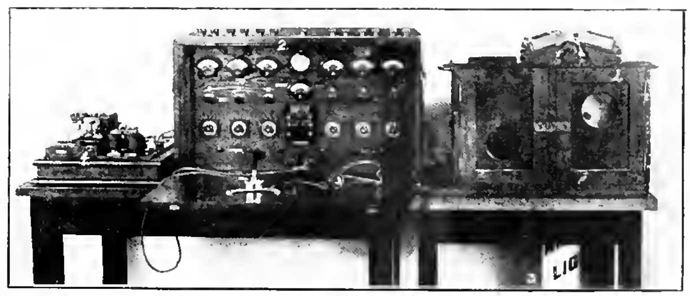

Fig. 5 Phonotelemeter—American Sound-Ranging Set for Locating Enemy Batteries

and time again, but the following facts as brought out by one of the exhibits may perhaps be of interest.

The Central Camouflage Works at Dijon produced daily 50,000 sq. yd. of camouflage cover. This tremendous output soon exhausted both the European and American supply of burlap, which formed the chief material for sniper suits, camouflage loopholes, observation posts, etc. A more economical material was soon developed and produced in the United States. This consisted of a 2-in. wire mesh partly covered with a light cloth and sprayed with paint. This proved very satisfactory and could be very easily and economically manufactured.

Listening and Sound-Ranging Apparatus

The exhibit of devices for locating mining operations, for detecting the approach of hostile aircraft, and determining the positions of the enemy guns was perhaps the most complete and entertaining of all.

Geophones and microphones, both mechanical and electrical types, were successfully used in stopping mining operations. These instruments, which operate in manner similar to the stethoscope, were developed by American engineers to such a point that their value was increased about 30 per cent.

Listening devices for determining the direction of approach of hostile aircraft at night had long been in use. The original long-horn listening device as built by the French (Fig. 3) was, however, a cumbersome affair and could be moved only with the greatest of difficulty. Again American methods came to the rescue, and an equally effective but portable apparatus of the parabolic type (Fig. 4), with the famous Ford wheel and axle again in evidence, with plaster-board detecting surfaces, was soon available; and, as might have been expected, at nearly one-third the original cost.

Perhaps the most delicate technical instrument developed and in use during the entire war was the phonotelemeter, shown in Fig. 5. This instrument not only locates an enemy battery, but it gives the caliber of the gun as well. These remarkable results are obtained merely from the report of the gun. The operation of the instrument is chiefly electrical, and, surprising as it may seem, it is not affected by rifle fire. A single set covers a 5-mile front, and it is reported that one section located 117 guns or batteries in 24 hours.

The English apparatus, known as the Bull-Tucker, makes a photographic record of the disturbance caused by the report of each gun. The French and American developments used a smoked tape for recording the firing, and to make the record permanent the tape is afterward sprayed with wax. This method gives the information desired in a much shorter time.

According to all reports, the Germans never possessed any such remarkable instrument, nor anything that could even be called similar in its nature.

It was by means of this instrument that one of the long-range guns which fired upon Paris was finally located and destroyed. After the armistice was signed, a survey taken by an American officer showed that in every case the location of enemy guns was within 20 to 30 ft. of that as determined by the phonotelemeter.

A flash-ranging device, also electrically operated, was extensively used upon the western front. This device is used in conjunction with observation telescopes for locating enemy batteries from the flash of their guns, and it proved very effective. It can be used either for day or night work.

The exhibits just described comprise the more important developments of the Engineering Department in the United States, and touch only here and there upon the activities of the Engineer Corps in France. "Over there," of course, the real construction work was done, for all fortifications, roads, railways, docks and warehouses, camps and hospitals, water-supply systems and sewers were the work of the engineers.

READJUSTMENT OF INDUSTRIES TO PEACE CONDITIONS

By JAMES D. MAGEE,[1] CINCINNATI, OHIO

BEFORE discussing the problem of readjusting to peace conditions, it will be well to recall something of the organization of modern business. In pioneer days each family was nearly self-sufficing. It produced the things which it needed to eat and wear. Now, as the result of ever greater and more complex division of labor, the ordinary man spends all of his time performing some small part in the manufacture or marketing of a product. The result of the change is greater interdependence. The individual is dependent upon the proper functioning of the whole system for the disposal of the product in which he is interested and for the possibility of purchasing the things he desires. Again, it is well to recall the method by which the decision is reached as to what will be produced. With few exceptions things are produced because some one thinks it will be profitable to produce them. That is, price levels and profit margins are relied upon to direct production.

The problem confronting us as we entered the war may be stated in general terms as follows: We had certain limited amounts of labor, land, materials and equipment. Some of the men were to be taken as soldiers and sailors. The remaining labor and resources had to be utilized to provide the food and clothing and munitions for the army and navy or equipment to make them, as well as to support the home population. The problem was how to shift labor and equipment from non-essential to essential industries. The readjustment was brought about by the appeal to the desire for profits and by the use of priorities in the supply of materials and in transportation. Any quick readjustment is difficult, but this one was made easier because it took place in connection with an almost unlimited demand for the products of industry which showed itself in rising prices.

Now we have another problem of readjustment. The men are returning from France and the training camps. The Government demand, backed by unlimited purchasing power, has fallen off. The labor, land, materials and equipment must be used to make things wanted by people in general. This readjustment will be more difficult as it will probably take place with prices falling.

The nearest analogy to this condition in our history is the situation of the North after the Civil War. Then an army of a million men was demobilized without any trouble. Agriculture, manufactures, mining and foreign trade all increased. It will be instructive to examine the two cases to find wherein they are alike and wherein different.

The cases are alike in that the fighting in the Civil War was done mostly in the South and in the present war in Europe.

Our general economic organization has become more complex since the Civil War. Specialization and division of labor have been carried to a greater degree. At present many men's chances of employment depend upon whether people will want enough of a certain article to justify some one ordering a machine which will be used in making it. This complexity makes our present problem more difficult.

After the Civil War many of the men went west to take up the free fertile land which the Homestead Act of 1862 had made available. They could take up this land and at least make a living without needing to bother about markets. At present the free fertile land is exhausted, so this easy solution is not possible. Secretary Houston proposes to reclaim and irrigate land to give to the returning soldiers, using the labor of the soldiers, in this way helping to give employment in the transition period.

After the Civil War many of the returning soldiers helped build railroads in the West. While at present there is not much need for new railroads, there is certainly a great deal of deferred maintenance which should provide employment.

The Civil War brought an increased use of agricultural machinery in the North. By this means the total product was increased, although the labor force was smaller. The increased production lasted after the war and formed the basis for an export trade in agricultural products. Much machinery was introduced in manufactures also. The present war has both intensified the use of machinery and increased our equipment of various types of plants. It remains to be seen whether our initiative will be great enough to use the plants for peace goods and develop large production as was done after the Civil War.

It is hard to form a judgment in the matter of possibilities for foreign trade. Europe had not been involved in the Civil War, and when it was over was ready to take large quantities of our exports. At present there is no question about the need for food and equipment in Europe, but the credit arrangements present a serious problem.

We are decidedly better off with regard to our monetary system than the country was after the Civil War. The inconvertible greenbacks had driven gold out of circulation and prices moved wildly. Our present monetary system is sound. Prices rose compared with pre-war prices in both cases. Prices in 1866 were higher than in 1865 and after that declined gradually.

The whole problem of readjustment is one of producing things which satisfy the new demands. People desire many things they have been forced to do without for the period of the war, and many of them, for example, the railroad employees, have greater purchasing power than they have ever had before.

Synopsis of remarks before the Engineers' Club of Cincinnati, November 21, 1918.

Heavy Field Piece With Mobile Mount

By ENSIGN C. L. McCREA,[1] U. S. N. R. F.

DURING the war the Navy Bureau of Ordnance originated a number of remarkable projects, and their success has been due in no small measure to the sound engineering principles applied in design and construction. Practically all of this development work was done by officers of the reserve force, graduate engineers and men of high standing in their profession. Among their many remarkable achievements was the design and construction of an entirely new type of mount for a high-power 7-in. gun. The evolution of this mount dates back to our entry in the war.

The Navy was naturally charged with the organization of a convoy system and ships of the *Connecticut* class were at once assigned to this duty. This of course meant that the convoy was to engage submarines that might appear, and it is generally conceded that submarine-offensive guns must be light, quick, and hard-hitting.

It was therefore decided that an improvement in the armament of the battleships could be made by substituting 5-in. 51-caliber guns for the 7-in. 45-caliber battery. This change was approved early in 1918 and the substitution of guns was begun at once. This left a number of 7-in. guns available for other service, and the urgent need of our forces in France for artillery turned attention to the possibility of placing these excellent guns in action on the western front.

The Army soon received a number of these 7-in. guns, which they mounted on railway cars especially built with a drop-frame bed so that the entire gun and its mount, exactly as it was used on board ship, could be placed on it.

This method of mounting the gun was unfortunately limited in its use by the fact that the elevation set by the naval mount, 15 deg., was still maintained, which limited the range to 14,000 yd., or about 8 miles. Furthermore the heavy trunnion pressures arising from the short length of recoil, while entirely satisfactory on board ship, were troublesome on a railway mounting, and strong outriggers and considerable bracing of the car and bed were required when the gun fired at targets at an angle to the line of the track on which it was located.

The Navy, in considering the uses to which these guns might be put, naturally first thought of placing them upon railway mounts. They planned however to give the gun an elevation of 30 deg., to lengthen the recoil and to modify the mount so that little or no bracing would be required when the gun was fired. While designs for this type of railway mount were being worked out, word was received that better use could be made of the guns if a suitable field mounting were developed, and on March 15, 1918, work was therefore started along such lines of design.

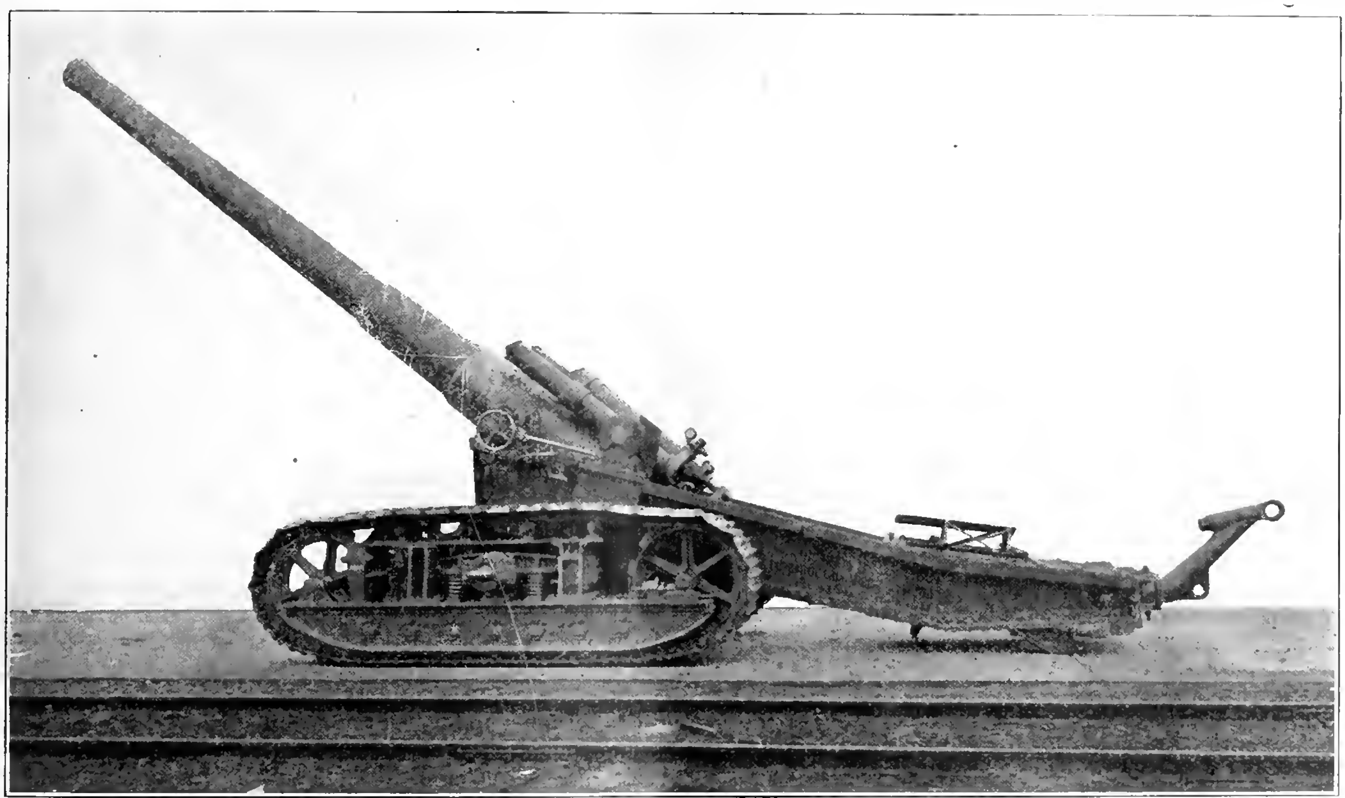

Fig. 1 High-Power 7-in. Gun with Caterpillar Mounting

The problem was to obtain a mobile field mounting for a gun weighing nearly 15 tons. The mount was also to permit transportation of the gun and mount as a unit, so that no preliminary preparation of the gun was necessary before firing. The 7-in. gun was the heaviest and hardest-hitting gun for which a mobile field mount of this kind had ever been contemplated, and in addition, the time allotted for design and construction was exceedingly short, as the mounts were desired in France before the close of the year 1918.

A study of existing designs was immediately commenced and it required but little study to show that a wheeled mount for the 7-in. gun was not practicable. The weight of the completed mount would be in the neighborhood of 70,000 lb. Assuming a 6-ft. wheel and an arc of contact of 25 deg. with the ground, the total bearing surface to carry the load would be about 6 sq. ft. This gave a ground pressure of about 6 tons per sq. ft., or 88 lb. per sq. in., a pressure of course out of the question, as the gun would undoubtedly become hopelessly mired

[1] Bureau of Ordnance, Washington, D. C.

when it encountered even slightly soft ground. Furthermore, large-wheeled mounts are difficult to place into position and correctly aim, and their tendency to roll back on firing makes rapid and continuous fire a difficult task.

In the face of these difficulties, a search was made for some better method of mounting the gun, and the principles of the so-called "caterpillar" belt for transporting the mount were suggested. Instead of wheels it was proposed to use a steel frame with rollers carrying a link belt presenting a large surface to the ground. Such a mount had never been used for a gun in which the reactions and weights were so great, and yet there appeared to be no serious objection to the idea. Sufficient strength could be given to the construction to carry the loads imposed, and preliminary calculations showed that a ground-contact area of 28 sq. ft. would be obtained, giving a pressure of 18 lb. per sq. in.—less than that of a horse. Designs for a mount of this construction were accordingly commenced.

It was hoped that a number of parts, such as the gun slide, recoil mechanism, etc., from the marine type of mount might be incorporated into the new land mount, but on consideration it appeared more desirable to lengthen the recoil of the gun as much as possible, reducing the trunnion pressure on firing, and in turn the weight of the mount, rather than to build a heavy mount capable of standing the heavy recoil forces. Furthermore, the counter-recoil mechanism was designed to return the gun to battery only at elevations up to 15 deg., and as an elevation of 40 deg. was contemplated in the new mount, a new design of counter-recoil mechanism was necessary. The designers therefore soon found that they must work from the ground up. Every part of the mount had to be newly designed, only the gun and yoke being used of the material taken from the battleships.

The Naval Gun Factory had preliminary designs for the new mount out within a fortnight. They called for a mount with caterpillar-belt wheels, a structural-steel carriage, made of shapes easily obtained, a gun slide equipped with hydraulic recoil and pneumatic counter-recoil systems and having an allowable travel of 32 in. in recoil, which reduced the trunnion pressures to approximately 120,000 lb.

The designs submitted were at least a year ahead of current development, yet they were so carefully worked out that they met with instant approval, and authority was given to proceed with the details. On May 25, 1918, the detailed designs were pronounced complete, and, shown on 164 separate drawings, were ready for submission to the bidders.

Design of the Mount

Caterpillar Wheels. The caterpillar wheels, on which the gun and carriage rest, are of the naval type. The wheel itself consists of an endless belt of cast-steel links connected by hardened pins. Each link carries a corrugated forged-steel plate which makes contact with the ground, the plates overlapping so that a continuous surface is presented. Detachable grousers are provided to prevent slipping when descending hills in rainy weather.

Within the belt are arranged the sprocket and roller wheels, all carried on a steel beam of special design. The sprocket wheels carry but little of the load, except when the gun is descending a hill or the brake is applied. Eleven truck and idler wheels, 7 below and 4 above, support the belt and carry the load.

A brake is provided to permit control of the mount when descending hills, and also to lock the caterpillar in position when the gun is set up for firing. This brake consists of a toggle joint operating on the rim of one of the sprocket wheels, and although exceedingly simple, has proved very satisfactory.

Gun Carriage. In the design of the gun carriage, standard structural shapes were utilized as far as possible, as it was realized that under existing war conditions special work could be obtained only with difficulty. The carriage consists of two side girders, cross-braced at each end to form a unit with a central well into which the gun recoils. A traversing gear is built into the rear end of the carriage to permit of accurate aim. This gear consists of a cast-steel plate which rests on the ground underneath the structural work of the trail, being held thereto by clips. A worm shaft operated by ratchet wrenches shifts the trail with reference to the plate and enables the gun to be accurately trained.

The trunnion seats are placed at the upper end of the carriage. Navy guns do not carry the trunnions attached directly to the gun, but are turned to a smooth surface on the outside. A cylindrical casting, known as the gun slide, to which the trunnions are attached, carries the gun. The gun slide also carries the recoil and counter-recoil mechanisms. These are contained in cylinders, and operate through pistons attached to the gun yoke. The slide is fitted with bronze liners, on which the gun bears when it slides in and out on firing.

In the 7-in. caterpillar mount the trunnions of the gun are mounted sufficiently high so that at maximum angles of elevation only a shallow trench about a foot in depth is required to allow clear space for the recoil of the gun.

Recoil and Counter-Recoil Systems. Recoil of the gun is taken up by means of a simple hydraulic brake, in which the energy is absorbed by forcing a mixture of glycerine and water through orifices of gradually decreasing diameter.

An elevation of but 15 deg., it will be remembered, was permitted by the mount in which the gun was carried on board ship. When so mounted springs were used to return the gun to the battery, or firing, position, and these functioned satisfactorily. The high elevation of 40 deg. permitted in the new type of mount, however, made spring return impossible.

Pneumatic system for counter-recoil return are in quite extensive use abroad, and these were investigated in the search for a proper mechanism. After a considerable study it was decided that the French type of mechanism, as used on 155-mm. guns, would do the work. In this type when the gun fires, a piston attached to the gun yoke moves backward in an airtight cylinder containing air at a pressure of several hundred pounds per square inch, and this air pressure brings the gun back when the gun has reached the end of its recoil.

The objections to the adoption of the French system were the exceedingly close limits to which it was required to machine the parts, and complications in the mechanism itself. Moreover, all the parts are arranged in one cylinder with a view to extreme compactness. Accordingly, the entire mechanism was redesigned to adapt it to American methods of manufacture.

In Fig. 1 the counter-recoil mechanism can be seen located on top of the gun slide (the recoil cylinder is located below). As redesigned, it is a combination of three cylinders, connected at the lower end by a cast bronze head. The piston attached to the yoke operates in the central cylinder. A simplified system of liquid packing is retained. The entire system is made up of shapes and materials easily secured, requires the minimum of machining, and on the whole is well adapted to American manufacturing methods.

Tests

On September 26, just one hundred days from the date the contract was placed, the first two gun mounts, complete and ready to fire, were shipped to the Naval Proving Ground, at Indian Head, Md. On their arrival the guns were first given a road test. Up hill and down they were hauled, over rough ground, and along hillsides at an angle. They proved themselves able to negotiate any ground over which the tractors themselves were able to operate. Obstructions were mowed down, and yet the weight of the gun and mount was so evenly distributed that no damage was done even to roads when it was necessary to traverse them.

The guns were proof-fired, and every expectation of the designers was fulfilled. The range of the gun, at its maximum elevation of 40 deg., was 24,000 yd., as predicted. No bracing of the mount was necessary other than a few timbers laid in the ground under the trail to distribute the load. The caterpillar tread, locked in position by the brakes, was as steady as a concrete foundation, and the gun remained steady on the point of aim even during continued firing. The counter-recoil mechanism and all the other parts of the mount functioned perfectly.

Diesel Engines and the Merchant Marine

Review of Developments on the Pacific Coast

In an endeavor to answer the question: Why is the internal combustion engine not used more extensively for marine propulsion? the San Francisco Section devoted its meeting of December 19, 1918, to a discussion of the Diesel engine as applied to the merchant marine. The papers presented were chiefly a record of past performances of motorships on the Pacific Coast, but it was also pointed out that the internal-combustion engines are rapidly assuming greater importance, and may ultimately replace the steam engine.

Bruce Lloyd, marine engineer for the Concrete Ship Section of the Emergency Fleet Corporation, discussed the attitude of the ship owner and gave valuable data of performances. George A. Dow, president of the Dow Pump & Diesel Engine Co., presented a paper on the Diesel oil engines of the motorship *Libby Maine*. Both of these papers are abstracted below.

J. H. Hanson, president of the Scandia Pacific Oil Engine Company, also read a short paper illustrated by about forty slides, covering the history and development of Diesel engines and showing some of the more recent installations on ocean-going vessels.

Perhaps the most interesting fact brought out by Mr. Hanson's remarks was the statement that there are nearly 800 motorships varying from 1000 to 12,000 tons capacity now in operation. Some of these ships are making from 40- to 50-day continuous runs covering more than 10,000 miles and carrying cargo of 11,000 tons. These ships consume during such voyages 400 tons of fuel oil instead of the usual 1500 tons of coal of the ordinary steamer, with a resulting saving of approximately 1000 tons in fuel and in addition making available another thousand tons of cargo space.

Diesel Engines on the Pacific Coast

Bruce Lloyd

The development of the steam engine, extending over a period of about one hundred years, has now reached such a stage that it is probably one of the most perfect machines that has ever been produced. The steam engine is wonderfully smooth-running and possesses great flexibility of power. And yet the ship owner is constantly being urged to discard his steam engine and install internal-combustion engines, and for the simple reason that the steam engine is not complete in itself. Its future is doomed by its necessary adjunct, the steam generator, which has never been improved so as to remove its attendant danger and other well-known disadvantages.

The space occupied by the boiler in a steamship, together with the large amount of room necessary for fuel, is the most perplexing problem that presents itself in the construction of a serviceable and economical cargo carrier. Attempts have been made to overcome this objectionable feature by placing the boilers on the upper deck of the ship, which is not so valuable for cargo space, but the fact remains that the boilers are still on board, adding at least their weight and detracting just so much from the general efficiency of the vessel.

In spite of the fact that the internal-combustion engine overcomes this difficulty and gives a tremendous advantage in cargo-carrying capacity, steam-driven vessels have been clung to with a tenacity equaled only by our forefathers in their unwillingness to discard the sailing ship and adopt the steamer. So strong was their distrust of the steam engine that it is only within the last fifteen years that owners of steamships were able to overcome their fears that the steam engine might break down and dependence have to be placed on sails, as all ships up to that time were provided with considerable sail area.

There are, however, other and perhaps more weighty reasons which prevent the ship owner from adopting the internal-combustion engine. Almost every port is provided with facilities for repairing the boilers and engines of the ordinary steamship; and engineers skilled in the operation of a steam engine are always available. On the other hand, facilities for ships whose motive power is the fuel-oil engine are not even now available.

Despite these disadvantages, however, the internal-combustion engine is rapidly being adopted by ship owners, and any reliable record of performance is at once a source of interest.

During the past two and one-half years 16 vessels on the Pacific Coast have been equipped with the Bolinder crude-oil engine, manufactured by J. C. Bolinder, of Sweden. Ten of these are so-called auxiliary ships in which the sail power predominates. All of them are engaged in overseas trade, visiting ports where fuel is either not available or only at prohibitive prices. Fuel tankage had therefore to be provided, of sufficient capacity to supply the engines, when running at full speed, for a voyage outward and homeward of nearly 17,000 miles.

These ships vary in size from 1500 to 3500 deadweight tons, and the size of the engines with which they are equipped ranges from 320 to 600 hp. These engines are of the direct reversible type. They have no camshafts or intricate gearing; a small compressor driven off the forward end of the crankshaft supplies air for vaporizing the fuel on entering the cylinder; and the reversal of the engine is affected by preignition.

The first large auxiliary ship equipped was the *City of Portland*, one of the three sister ships built and owned by the McCormick Steamship Company, of San Francisco. These vessels are approximately of 3500 deadweight tonnage and are equipped with twin engines of 320 b.hp. each. The engines have often run continuously for 45 days. The average speed maintained was 6.8 knots, but when the engines were allowed to develop their full power the speed averaged 7.5 knots. The sails were of practically no use on any of these voyages, and these vessels would more properly be designated as low-powered motorships.

The daily fuel consumption averaged 23 bbl. of oil of 24 deg. B. gravity, and for a voyage covering 17,000 miles, 1997 bbl. of fuel oil were used.

The motorships that have attracted the greatest attention, however, are the full-powered vessels, as these afford the best opportunity of comparison with steamships. Four such motorships (twin-screw) have lately been added to the fleet of W. R. Grace & Co. They are excellent examples of the possibilities of moderate-sized ships equipped with fuel-oil engines. These ships, all of the same design, are the *Santa Elena, Santa Isabel, Santa Cristina* and *Santa Flavia*, and their dimensions are as follows: Length, 235 ft.; breadth, 42 ft.; depth, 29 ft.; cargo capacity, about 2000 tons on 18 ft. 6 in. draft. The propelling machinery of each ship consists of two 320-b.hp. Bolinder engines. The main fuel supply is carried in steel tanks having a total capacity of 1770 bbl., sufficient for nearly 75 days' running, and the extensive radius over which these vessels are able to travel without refueling gives them an immense advantage over the ordinary steamer. The auxiliary machinery consists of one 15-b.hp. Bolinder engine direct-connected to a 10-kw. generator and one rotary pump of 2500 gal. capacity; also one 8-b.hp. Bolinder engine connected to a 5-kw. generator and rotary compressor. These ships carry a refrigerating plant consisting of a 1-ton Brunswick motor-driven ice machine, and each has about 600 cu. ft. of refrigerating space. All of these vessels have completed voyages to New York, via Valparaiso, calling at other South American ports and the Panama Canal—a distance of over 14,000 miles, at an average speed of 180 nautical miles per day.

The engine troubles that developed have been chiefly cracked cylinder heads and broken compressor shafts. It was noted that the fracturing of the cylinder heads always occurred while maneu-

vering the engine in entering or leaving port, and never at sea. This, it was found, was caused by the overheating of the head when the engine stopped, as the circulating pump of the water-cooling system was driven from the main crankshaft. The sudden cooling and contraction which thus took place when the engine was started again has been entirely eliminated by devising means to keep a constant circulation of water through the cylinder heads even while the engine is at rest.

The breaking of the compressor shaft which occurred in the first three installations was due to a mistake in design which was quickly and easily rectified, and there has never been a recurrence of this trouble.

A steel motorship of 3500 tons carries on a direct voyage of 8,000 to 10,000 miles nearly as much revenue-producing cargo as a steel steamer of 5000 tons of the same speed, as the following table clearly shows:

	Motorship.	Steamer.
Deadweight tonnage	3500	5000
Fuel oil for 45 days at 5 tons per day, tons	225	....
Coal for 45 days at 25 tons per day, tons	....	1125
Water for boiler, tons	...	100
Net paying cargo, tons (deadweight tonnage minus fuel and water)	3275	3875

It is not intended, however, to advocate the internal-combustion engine for passenger ships, or for vessels carrying cargoes which must be transported within the shortest possible time, since in these cases the necessity for speed relegates the question of economy to a place of secondary importance.

Merchant ships and steamers, on the other hand, are operated solely for profit, and the hull that can carry the most cargo at the lowest cost is obviously the best.

In 1911 a ship propelled by a new type of engine entered our port after making a most successful voyage from Copenhagen, Denmark. This vessel, the motorship *Siam*, was owned by the East Asiatic Co., and equipped with a type of engine known in Europe as the Diesel engine. Vessels propelled by this new type of engine repeatedly visited our coast and soon were making the trip to the Pacific Coast and thence to the Orient and back in a perfectly satisfactory and efficient manner.

In 1916, when ships were greatly needed to carry our products to Europe and were being built as rapidly as possible, the great problem of obtaining machinery presented itself. Engine manufacturers were building steam engines and boilers for large steel ships and could give no time to the building of engines for smaller craft. The average ship owner was therefore glad to get whatever he could.

When the wooden sailing vessel was decided upon to meet the great emergency, the so-called semi-Diesel type of engine was adopted as an auxiliary. Subsequently, however, it was used as a full-powered propelling unit and thus a practice new to the shipping men of the Pacific Coast and untried by the manufacturers came into vogue. Since this proposition at once had associated with it the successful practice of the Europeans, the semi-Diesel gained great popularity.

A good many types of American-built Diesel engines have been installed and tried out. Marine engineers have had their opportunities to prove their skill in operating them, and the time is rapidly approaching when the ship owner will see that the American-built internal-combustion engine occupies a front-rank position as a prime mover in ship propulsion.

Performance of the "Libby Maine"

George A. Dow

A Diesel-engine installation watched with unusual interest on the Pacific Coast is that on the *Libby Maine*. This vessel is a 2000-ton wooden ship of very rugged construction, and built especially for severe arctic service. She is 240 ft. long, 43 ft. beam, 24 ft. molded depth, has a mean draft of 22 ft. 8 in., and is equipped with two 424-i.hp. Dow full-Diesel-type oil engines. These are direct reversible and are connected through Falk reduction gears and Nutall flexible couplings. Each unit is tied to an engine bedding designed to give the maximum stiffness and greatest security against deflection. Heavy timbering securely bolted to the ship's frames run in single lengths the entire length of the engine unit. The Nutall flexible coupling is placed between the main engine and reduction gear to relieve any possible strains between these units, as well as to act as a float. The reduction gear and thrust block are bolted to a single heavy cast-iron sub-base. By the use of the reduction gear the most efficient engine speed of 250 r.p.m. and the most efficient propeller speed for this size of ship, 100 r.p.m., are obtained.

The engines installed in the *Libby Maine* are of the six-cylinder open A-frame type of construction. Six cylinders were used in order to give maximum flexibility and positive starting positions, and the A-frame design was adhered to because it afforded the greatest accessibility to the bearings and pins. Marine engineers are anxious to know where their pins and bearings stand and feel more secure when they are able to "feel" parts subject to heating.

The cylinders are separate castings; cylinder heads are of standard box construction and pistons are of the long trunk type. The crankshaft is in two sections, the forward and after section being interchangeable. The lubricating system is controlled by drip oilers, the oil being measured into individual positively timed oil pumps attached to each A-frame. One plunger of this pump supplies the piston lubrication and the other the piston pin. The main bearings are lubricated by ring oilers and the crankpin by centrifugal oil rings.

The operation of the entire engine is controlled by three levers centralized at one station. A novel feature of this installation is that one man is able to control both engines from one platform. Even in the treacherous waters of the Bering Sea this control was absolutely responsive to the captain's wish.

Two levers are used to govern the action of the engine, while the reversing mechanism is manipulated by the third lever. Reversing is accomplished by the single movement of a vertical sliding cam, actuated by an oil-compensated air piston, which automatically lifts the cam rollers clear of all the cams, then slides the camshaft to the desired position and finally returns the cam rollers to the cams, thereby giving the proper timing of the valves for the new direction of rotation.

Air pressure is then applied to the pistons of the engine through the air starting valves by a single movement of the control lever until momentum is acquired, when another single movement of the same control lever automatically cuts off the air pressure and admits the fuel oil to the cylinders. The entire mechanism is thoroughly interlocked to guard against any false move on the part of the operator. Automatic locking devices block the execution of any movement not made in the proper sequence. The speed of reversal is controlled by the pressure of the air applied to the air piston of the reversing cylinder and the regulation of the velocity of oil displacement from one side of the piston to the other.

In order to obtain flexibility of operation, economic use of starting air, and added security against a shutdown of the entire unit, two control levers are provided, one lever for each set of three cylinders.

The general characteristics of the engine are: i.hp., 425; bore, 12 in. stroke, 18 in.; crankshaft diameter, $7\frac{1}{2}$ in.; speed, 250 r.p.m.; floor space, 20 ft. by 5 ft. 1 in.; height above center of crankshaft, 8 ft. 10 in.; approximate net weight, 125,000 lb.

An ideal trip from Seattle to Honolulu and return to San Francisco was experienced and a record in fuel economy made. Extracts from the official log indicate the following:

Fuel-oil consumption, bbl.	259.5
Total distance, miles	2440
Time of voyage	14 days, 18 hr. 15 min.
Average economy, gal. per nautical mile	4.46
Average speed, knots	7

From San Francisco to Seattle very heavy weather was encountered. The chief engineer reported that the screw was out of the water half of the time, but no racing occurred at any time, due to the perfect action of the governors.

The engines of the *Libby Maine* are an example of approved European practice adapted to the needs of the Pacific Coast and stand as a milestone of progress in the use of the internal-combustion engine as applied to marine propulsion.

Mechanical Features of Vertical-Lift Bridge

A Veteran Bridge Engineer's Comments on Mr. Van Cleve's Annual Meeting Paper, Together with Details of a Recently Constructed 260-ft. Double-Track Lift Span

By DR. J. A. L. WADDELL, KANSAS CITY, MO.

At the 1918 Annual Meeting a paper of the above title, presented by Mr. H. P. Van Cleve, dealt with the important developments in the operating mechanisms of vertical-lift bridges during the past 25 years, and devoted special attention to structures designed and constructed under the supervision of Dr. J. A. L. Waddell, the eminent bridge engineer and author of treatises on bridge engineering. Dr. Waddell has been good enough to supplement Mr. Van Cleve's presentation by the following additional particulars of some of the structures described in the paper, as well as by details of a new lift bridge at Louisville, Ky., embodying his most recent ideas in design. A comprehensive abstract of Mr. Van Cleve's paper appeared in The Journal of November 1918, p. 938.

MR. VAN CLEVE'S excellent paper has proved of special interest to the writer, who may justly claim to be the father of the modern vertical-lift bridge. His first design, made in 1892, was for a 250-ft. span at Duluth, Minn., to cross the canal which forms the entrance to the harbor of safety for lake vessels in that vicinity. The War Department prevented the building of the structure, but in 1902 permitted at the same location the construction of a *transbordeur*.

Soon after the rejection of his plans for that proposed bridge, the writer was retained to design and supervise the construction of a similar but shorter-span bridge at South Halsted Street, Chicago, the first bridge mentioned by Mr. Van Cleve in his paper. This structure was built under great difficulties and in spite of many discouragements. The Chicago engineers as a body were opposed to this type of bridge; and the then highest authority on bridges in America, the late George S. Morison, stated flatly that it could not possibly operate, and that it would be impracticable to raise the span off the piers. On the strength of this statement the City Engineer, Mr. Geraldine, made all the arrangements for canceling the contract for the construction, although some of the substructure had been completed and a large portion of the metal-work had been manufactured. It took some very earnest pleading by the writer to persuade him to permit the work to proceed; and the said pleading would not have been successful had it not been for an important fact pointed out, viz., that the city of Chicago would have had to pay the full contract price for the structure whether it were built or not.

The specifications called for the lifting of the span to the full height (involving a raise of 140 ft.) in 60 sec.; and, much to the surprise of everybody, on the first trial the span went up in about half of that time. Afterward the writer timed the operation, both up and down, and found that the span could be moved over the full height in 28 sec. This was certainly a great triumph for a comparatively young engineer in a struggle with the local technical body, including the highest bridge authority in America.

Referring to the Keithsburg bridge which Mr. Van Cleve mentions, the heavy-duty, slow-speed gasoline engine used is clumsy, ponderous, and conducive to jar, although undoubtedly effective. It is quite certain that a light, high-speed type, such as the automobile or tractor engine, will prove more satisfactory for future lift bridges.

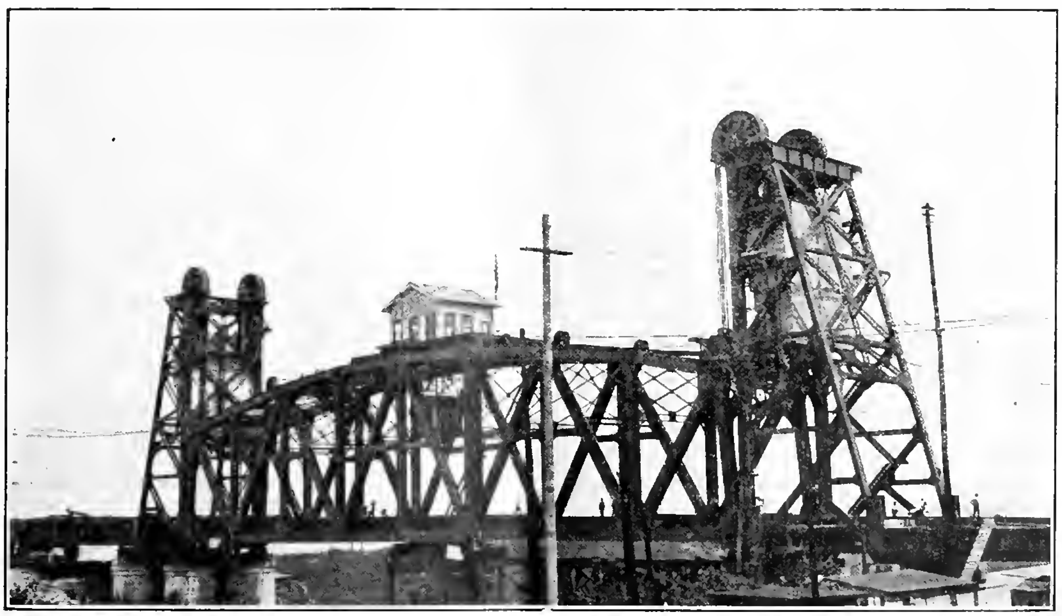

Fig. 1 Double-Track Lift Bridge of Pennsylvania Lines at Louisville, Ky.

In truth, though, gasoline engines are to be used for lift bridges only as a last resort or as an auxiliary; because electric motors are far superior in every respect. Again, direct-current motors are much more satisfactory than alternating-current motors; and, consequently, they should be used whenever an ample direct-current supply of power is obtainable. The writer is pleased to see that Mr. Van Cleve has called attention to these important points.

Mr. Van Cleve mentions that the heaviest sheaves yet used for any vertical-lift bridge were those for Bridge No. 458 of the Pennsylvania Lines West of Pittsburgh, and that each sheave weighs 31 tons. Within the last few weeks there has been completed for the same railway company a vertical-lift bridge, designed by Waddell & Son, Inc., across the Louisville and Portland Canal that lies adjacent to the Ohio River at Louisville, Kentucky; and the sheaves for this structure weigh 38 tons each.

As this is the very latest thing in lift-bridge construction, the following description of the structure should prove of interest:

The double-track span, which is 260 ft. long between centers of end bearings, weighs about 3,000,000 lb., and is lifted 32.4 ft. in 45 sec. There are 64 counterweight ropes $2\frac{1}{8}$ in. in diameter, passing over the four 15-ft. sheaves. The motive power consists of two 150-hp., 220-volt, a.c., 60-cycle, 580-r.p.m. motors equipped with solenoid brakes. Magnetic control is used. Speed reduction from the motors to the winding drums is made through a train of three sets of spur gears to a cross-shaft having a pinion at each end meshing with two drum gears.

The span is shown complete in Fig. 1 and the operating machinery in Figs. 2 and 3. Fig. 4 shows the operating drums which

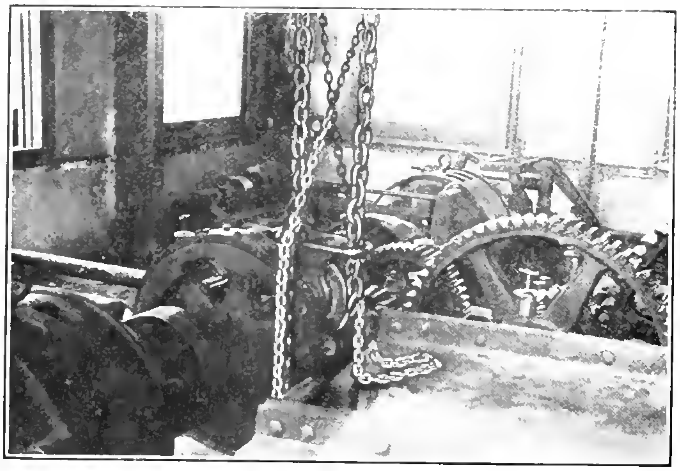

FIG. 2 MACHINERY HOUSE OF LIFT BRIDGE SHOWN IN FIG. 1

raise or lower the span and which are quite similar to those used in the Don River bridge in Russia. However, the detail of the cross-shaft has been improved by adding two bearings and two couplings, thus giving more rigid supports for the pinions and making the lengths of shaft between the center main frame and the drum frames truly flexible. This detail eliminates entirely any trouble from errors in the alignment of the three frames, which otherwise would cause considerable friction and loss of power. Hand operation is provided for by two 4-arm capstans.

There are 16 plow-steel operating ropes, each 1 in. in diameter, the drums and sheaves over which they run being 36 in. in diameter. These ropes work in pairs, i. e., there are two up-haul and two down-haul ropes at each corner of the span. The take-up devices for the ropes are eyebolts threaded over the entire length, with anchorage attachments at top and bottom of towers.

The counterweight sheaves, the heaviest yet built, are constructed of steel plates, angles and castings. In their designing special care was taken to eliminate the troubles which had arisen in connection with the built-up sheaves described in Mr. Van Cleve's paper. Each rim segment is fastened to the side plates by a sufficient number of rivets to take the entire load coming upon it from the ropes; and $\frac{1}{2}$-in. spaces were left between the segments, so that there might be no trouble if the lengths of the segments should overrun. It was originally intended to fill these spaces with hemp; but the cutting tools gave trouble when the machining of the grooves was begun; and it was found necessary to fill them with babbitt. The trouble previously experienced from bad fit of side plates on the hub casting was eliminated by making the said side plates bear directly on the shaft instead of on the hub casting. The hole for the shaft was bored out after the sheave was completely assembled and riveted. The journals are $22\frac{1}{2}$ in. in diameter and 24 in. long, the overall length of the shaft being 7 ft. 8 in. The hub is keyed to the shaft by three keys $1\frac{1}{2}$ in. wide and 1 in. deep, secured from longitudinal movement by set screws. The bearings are lined with phosphor-bronze bushings for high pressure and low speed. Oil grooves are cut into the bushings, the lubricant being supplied from marine-type, screw-feed, compression grease cups.

The rail locks are of sliding-tongue type, standard with the Pennsylvania Lines. The four tongues at each end of the span are driven by a 5-hp. motor. Limit switches are provided to cut off the current at each end of the travel. The controllers for the rail-lock motors are interlocked with the signal system, so that the locks cannot be opened until the signals are set against train movements over the bridge, and so that clear signals for train operation cannot be given until the locks are closed. The controllers are also interlocked with those for the main operating motors so that current cannot be supplied to the latter until the locks have been opened, and so that the locks cannot be closed until the bridge has been seated.

The span is kept in correct position during motion by guide rollers, which roll on vertical guides on the outsides of the tower columns. There are eight rollers for transverse guiding, one at each L_0 point and one at each U_0 point. Longitudinal guiding is effected by two rollers at each L_0 point at the fixed end of the span. There is considerable play in the guides, so as to eliminate any possibility of binding. On account of this play they do not center the span closely enough for the rail locks, which have very little play. For this reason there is placed a transverse centering casting, having very little play, at the middle of each end floor beam. In earlier designs a transverse centering casting was placed at each L_0 point; but considerable play had to be left in these castings to provide for expansion and contraction, and they did not center the span accurately enough for the rail locks.

The train thrust is cared for by two thrust castings, one at each L_0 point at the fixed end of the span.

In order to eliminate jar when the span seats, there are provided air buffers near each end of each of the end floor beams. Adjustable needle valves on the exhaust ports of the buffers enable the resistance of the said buffers to be varied at will.

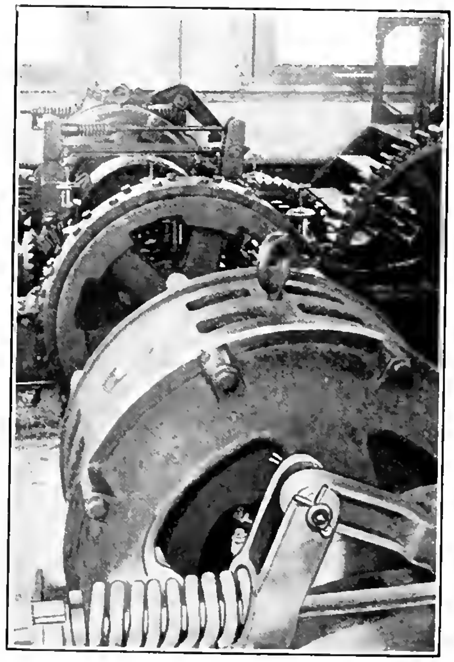

FIG. 3 MOTORS AND BRAKE SHAFT OF BRIDGE SHOWN IN FIG. 1

Bridge locks were not used, but the counterweights were made about six tons lighter than the span, the excess weight of the latter overcoming any tendency for it to rise.

The span can be handled from the machinery house, which is located at the center thereof, or from an interlocking tower on shore about 100 ft. from the south end of the span. It is intended to operate the span from the machinery house until the operators become thoroughly familiar with the manipulation, after which it will be operated from the interlocking tower. Duplicate switchboards, with indicator lamps, meters, etc., are placed in each house. The main switchboards and the resistances are located in the machinery house.

As was stated previously, each motor is equipped with a solenoid brake. In addition there are a hand brake and a motor-operated brake. The lever of the hand brake is in the machinery

house on the span, and gives the operator graduated braking power, so that he can stop the moving mass without jar. The controller of the motor-operated brake, which has three degrees of braking power, is located in the interlocking tower. These braking devices are not of great importance in a slow-moving bridge like this one; but for a high-speed bridge, which will coast for several feet after the current has been turned off, they are much more important.

The erection of the lift span was quite difficult, as traffic had to be maintained over the bridge and navigation could not be interfered with. The old moving span was a swing. It was at first proposed to erect the new span in its fully lifted position. As the counterweights would then have to be built at the lowest point of their travel, it would have been necessary to leave large notches in them for the passage of trains. This scheme was abandoned for that and other reasons, and a new one was worked out. Permission was secured from the United States Government to leave only a 100-ft. channel near the north tower. This channel was spanned by a plate-girder lift span of the same type as the main span, worked by hand-operated crabs. After the main-lift-

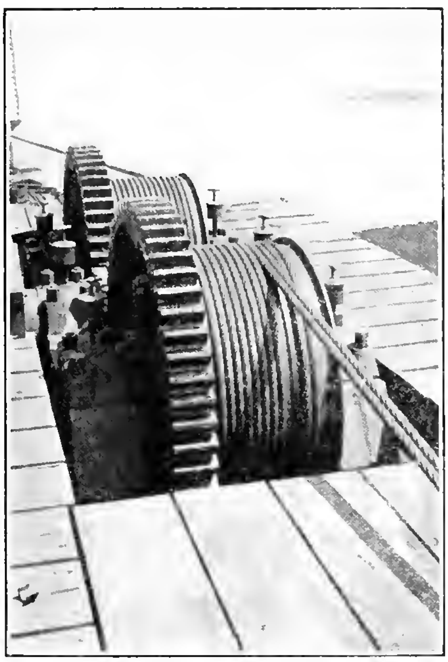

FIG. 4 UPSTREAM DRUM OF BRIDGE SHOWN IN FIG. 1

span towers were partly erected, navigation was stopped for a few hours while one end of the swing span was removed, the gallows frames for the plate-girder-span towers were erected, and the plate-girder span placed in position. The remainder of the swing span was then removed, the towers erected, the sheaves and ropes placed thereon, and the counterweights constructed on falsework resting on the piers and floor beams. The south portion of the lift span was then erected, also the north hangers; and the counterweight ropes were attached. The machinery was erected complete and thoroughly tested out. Navigation was then closed for a day, the plate-girder span removed, the remainder of the lift span erected and riveted, and the operating ropes connected up.

Special care was taken in the aligning of the main-sheave bearings. This was done by means of a steel straight-edge as long as the shaft. The bushings had been scraped to fit the shafts in the shop, the shafts and bushings being matchmarked. The aligning was so carefully done that when the sheaves were hoisted up they fitted perfectly in the bearings, and each 38-ton sheave could be rotated by one man. The machinery and motors were also aligned and tested out very carefully. The motors were run for several hours before the operating ropes were attached to the drums, in order to get the machinery into smooth-running condition and to determine if there were any poorly aligned bearings. Any hot bearings which developed were realigned. The machinery and the electrical equipment were in perfect operating condition before the operating ropes were attached to the drums and before the plate-girder swing span was removed.

Waddell & Son, Inc., has lately designed deflection bearings for main sheaves which insure a uniform pressure over the entire length of the journal. With the high bearing pressure used in the design of journals for lift-bridge sheaves and bascule trunnions this is extremely advisable. The use of this type of support greatly simplifies the problem of aligning the bearings.

One general fault of the electric equipment of movable bridges may be pointed out—that of using too small power lines. The overload capacity of the motors for vertical-lift bridges is called into play if a span becomes unbalanced, and, for bascules, when operating against a high wind; and this requires power lines of ample capacity. This point is not quite so serious in the case of direct-current motors, as the drop in voltage in the power line will merely cause the motors to run slower; but with alternating-current motors the drop in voltage reduces the torque materially, because the torque of such a motor varies as the square of the voltage. For instance, a 10 per cent drop in voltage means nearly a 20 per cent drop in torque. This point requires special attention when the power lines are long.

In spite of all the opposition which the vertical-lift type of movable bridge has encountered in the last quarter of a century (some of it being very bitter and most of it totally unfair), that type has come to stay; and it will be used more and more in the future, after railroad and city officials overcome their prejudice against the use of wire rope and learn that, for economy in first cost, simplicity of design, quickness of operation, rigidity under load, and economy in maintenance and repairs, it is unequaled by any other type yet evolved.

COMMENTS ON DR. WADDELL'S COMMUNICATION BY MR. VAN CLEVE

The writer has been much interested to read Dr. Waddell's comments on his Annual Meeting paper, and also to learn something of the details of the Louisville lift bridge, the only one so far constructed with which he is unfamiliar.

The guiding, centering, and interlocking details described have all been used on previous bridges, but the operation of the span from a point on shore a distance as great as 100 ft. from one end of it, is new and deserves some comment.

To the writer this feature seems objectionable, mainly because it would put the operator somewhat out of touch with the requirements of passing boats, but also because it would prevent that vital contact with the movement of the span which goes a long way toward preventing careless operation. The writer has been present during operation on ten lift spans of this type, sometimes as operator, and sometimes as observer, and he feels that the presence of the operator on the span is, while not absolutely necessary, at least very desirable; and that if it seemed best to have one man operate both the track signals and the lift span, it would be better to place the signal stand on the lift span than the span master controller in the signal tower. This alternative may have been considered in the case under discussion, and found impossible, but it was done very satisfactorily in the case of the C. & N. W. Ry. bridge over the Illinois River at Pekin, Ill. In this installation all track switches and signals are thrown electrically, but this is not necessarily the case, as demonstrated by the fact that at least one of the lift spans now in operation carries on its deck some twenty lines of pipe of the signal system which automatically unjoint at both ends of the span when the latter is lifted.

Referring to Fig. 1 in the paper on The Conservation of Heat Losses From Pipes and Boilers by Glen D. Bagley, published in the November 1918 issue of THE JOURNAL, p. 918, the heat loss per square foot per hour, per degree fahrenheit difference, should have been given *without* the decimal points, in the first vertical column.

Properties and Preparation of Glues

Data on the Properties, Preparation, Classification, Grading and Testing of Glues, Strength of Glued Joints, etc., Based on Experimental Work of Bureau of Aircraft Production

GLUE is a subject which has become of particularly great importance since the development of the use of veneer construction in aeronautics, and the following data, abstracted by special permission of the Bureau of Aircraft Production, War Department, from a confidential bulletin,[1] and based on experimental work done in the laboratories of the Bureau at McCook Field, Dayton, Ohio, are accordingly of more than ordinary interest.

Glue is defined as an impure form of gelatine possessing the property of adhesion, which differs somewhat from the popular understanding of the word, which is taken to include all substances having adhesive qualities with the exception of certain types of cements, shellacs, etc. Glue, however, is really a compound consisting of a large proportion of gelatine with certain other substances, such as chondrin, keratin and mucin, associated with it, and, in general, the glue advances in the scale of purity as the ratio of gelatine to the other substances present increases.

Classification and Most Desirable Properties

Glues are classified in accordance with the substances from which they are made, as follows:

1 Bone glues from the horns, raw bones of heads, ribs, shoulder blades, etc., of domestic animals.

2 Hide glues from tannery waste, such as skin trimmings, etc.

3 Sinew glues from the sinews of cattle.

4 Fish glues from fish offals, air bladders and membranes.

5 Casein glues from fermented milk and other milk products.

6 Egg-albumen glues.

7 Blood-albumen glues.

8 Vegetable glues from certain non-nitrogenous vegetable growths, such as Irish or Iceland moss, agar-agar, seaweeds, gums and dextrines.

The above classification includes all the most important groups. Other divisions are possible, such as hot and cold glues, liquid and solid products, etc., but these will be considered later.

The most desirable properties of a glue are:

1 Strong adhesiveness.

2 Tenacity, which is slightly different from adhesiveness, and which may be defined as the power to resist the disruptive effect of a stress in any direction.

3 Elasticity, or the power to stretch slightly without fracture. In this connection the moisture content is a very important factor, as glues which are too dry are often inclined to be brittle. While such glues may stand an enormous stress under a steady load, the sudden application of a comparatively light load is liable to cause failure. The constant vibrations, varying stresses and shocks to which airplane members are subjected make it vitally important to select for airplane construction a glue with a fair amount of elasticity as well as high strength.

4 Covering power. This can be determined by estimating the water absorption, the tenacity of the jelly and the viscosity of a solution of known strength.

5 Practical working qualities. Among the most important properties of glue are its workability in the shop, rapidity of setting, etc.

Casein and Blood-Albumen Glues

The original paper describes the process of manufacture of the various types of glues and the manufacturing elements which determine the properties of the final product. From this point of view the most interesting parts are those referring to casein glues and blood-albumen glues, on which very little printed information is available. The following data are presented in the Bulletin:

When the sugar of milk ferments, producing lactic acid, the milk turns sour, and casein, the characteristic proteid of milk, is separated in a coagulated mass, due to bacterial action. Casein also may be produced by adding acetic acid to fresh milk which has been diluted and warmed. An appreciable excess of acid must be employed, however, as exact neutralization of the diluted milk with acid does not precipitate the casein, owing to the interference of the alkaline phosphates present in the milk.

In the manufacture of casein glue, the commercial casein is purified by alternate solution in alkali and precipitation with acid, the precipitate being thoroughly washed each time. The number of these treatments determines the purity of the product, and hence its price.

Certified casein glue is supplied by the manufacturer in the form of dry powder, the chief constituent of which is the casein derived from milk as just described.

There is not very much information available at present concerning the manufacture of blood-albumen glue. It is made from blood, or from serum albumen resulting from the evaporation of the separated serum of fresh blood. The evaporation is conducted at about 50 deg. cent., and the albumen is obtained in the form of flakes varying in color from grayish to black. Three or four qualities of blood albumen are known, the purest being a dirty yellow and the poorest, black. Similar to the casein glues, the blood-albumen variety is waterproof.

The article gives some data as to the preparation for use and method of application, especially in regard to casein glues. From this it appears that the principal difficulty encountered with the casein glues lies in the rapidity of setting after mixing with water, as it seems they set at periods from 30 min. to 5 hr., depending on the brand.

Strength of Glued Joints

Factors affecting the strength of a glued joint are enumerated in the following order:

In the first place is mentioned the skill of the operator; next, and being of almost equal importance, is the quantity of glue which penetrates into the pores of the wood; and, finally, the avoidance of the formation of air bubbles which frequently cause the failure of a joint. With blood-albumen glues the question of mixing and application, especially as regards temperature, is very important, as the glue does not spread properly if too cold.

In another part of the investigation, referring, however, more specifically to casein glues, the following enumeration of factors affecting the strength of the joint is given:

1 Kind and quality of the wood to be used.

2 Nature of the joint.

3 Quality and condition of the glue.

4 Temperature of the glue, of the surfaces of the joint, and of the surroundings.

5 Hygroscopic condition of the wood.

6 Method of application of the glue.

7 Amount and duration of pressure to be employed.

8 Time and conditions of setting, and subsequent drying of the glued joint.

9 Nature of the strain to which the glue is to be subjected.

A highly interesting section of the paper refers to the subject of testing of glues. This is a matter of considerable difficulty, as

[1] Bulletin of the Experimental Department, Airplane Engineering Division, U. S. A. (Bureau of Aircraft Production, War Department—Confidential), vol. 2, no. 3, December 1918, pp. 5-26, 10 figs., *cpA*.

there are no specific standards for such tests, and the whole subject is on a very indefinite and unsatisfactory footing. In fact, it appears that under one class of test a good glue may show up excellently, while under some other testing method the same material may not indicate nearly as good results.

Testing of Glues

The tests may be divided into two main classes; chemical and physical. The former are of particular value only in special cases. The physical tests appear to be of more immediate value.

The first examination is sometimes instructive. Thus, the odor of the glue affords some indication of its quality, as a glue having an offensive smell is not considered of the highest grade.

The preservative quality of a glue is determined by allowing the jelly left from the jelly strength test, during manufacture, to stand in the laboratory at room temperature for a number of days. The odor and condition of this stock are noted at intervals. Glues with good keeping qualities will stand several days without developing an offensive odor or showing any appearance of decomposition.

The consistency of the jelly test suggested by Lipowitz in 1861 has been extensively adopted for commercial purposes. For this test 5 grams of glue are soaked in water at room temperature and then dissolved in enough water at 70 deg. cent. to make the total volume 50 cu. cm. when cold. The solution is allowed to stand in cylinders $\frac{1}{2}$ in. internal diameter for 12 hr. at 18 deg. cent., and the consistency value of the jelly is then determined by inserting in the jelly a small pointed plunger with a funnel at its upper end, which is gradually loaded with the lead shot until the load is just sufficient to force the plunger entirely through the

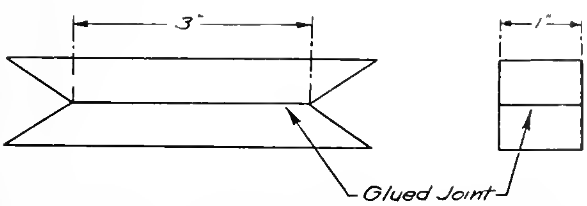

Fig. 1 Joint Used by the British Royal Aircraft Factory for Testing Glues

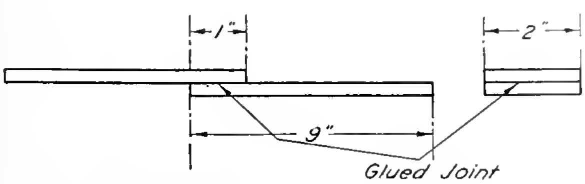

Fig. 2 Standard Test Block Used for Testing Glues by the Aeronautical Inspection Directorate, U. S. Army

jelly from its top surface to the bottom of the cylinder. The weight of shot necessary to effect this gives the Lipowitz number.

At the Aeronautical Inspection Directorate Laboratories a round-ended glass rod is employed instead of a pointed steel plunger, and the results obtained have been found to be more consistent and satisfactory.

The jelly consistency test is usually accompanied by a viscosity determination of glue solutions. The American Air Service criterion, formerly used, that "the strength of the glue in shear shall not be less than that of the wood," is not sufficient, it is stated. A very poor glue could be made to pass the specification merely by selecting for the test wood which was considerably below the average of the species in tenacity. The test may be made unfair by using a wood of unsuitable grain.

The method officially adopted in Germany is the Spandau test, described as follows:

It consists in gluing together with a plain butt joint, end grain to end grain, two blocks of wood 40 mm. in cross-section and 210 mm. long. Glue stock for the test joint is prepared by dissolving 250 grams of glue in 500 cu. cm. of water, and reducing the solution thus obtained to half of its original volume by evaporation. This is done in order to ascertain whether the prolonged boiling necessary to evaporate the solution will have any tendency to reduce the adhesive properties of the glue.

The blocks of wood having been glued together, one is fixed horizontally to a table in such a manner that the joint between the two blocks overhangs a few millimeters beyond the edge of the table. A scale pan is attached to the block a given distance beyond the edge of the table, and weights are placed in the scale pan until fracture of the glue joint takes place.

The British Royal Aircraft Factory has a standard glue test which is a modification of the Spandau method.

According to R. A. F. specification dated Nov. 21, 1916, a double-wedge-shaped test block is made up by gluing together two pieces of black American walnut, as shown in Fig. 1. The glue solution is prepared according to the instructions issued by the manufacturers of the material. Thus made, the test joint, meas-

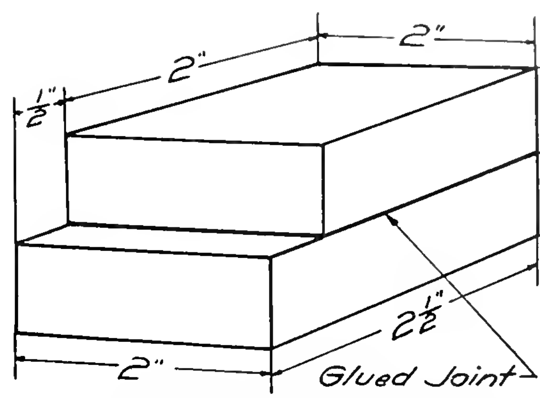

Fig. 3 Test Specimen Described in Bureau of Aircraft Production Glue Specifications

uring 3 in. by 1 in., is required to support a static load of 187 lb. per sq. in. under the following conditions:

1 Dry-heat test. The test piece must support its static load at 122 deg. fahr. for 30 min.

2 Humidity test. It must support its static load in a fully saturated atmosphere for 25 min.

3 Submerged test. The test piece, submerged in water, must support its static load for 36 hr.

It is to be noted that the Spandau test subjects the glue to a combined shear and tensile stress, while by the R. A. F. method a direct tension seems to be intended.

Strength tests conducted by the laboratories of the Aeronautical Inspection Directorate on glue intended for use in the construction of aircraft are unlike either of those methods previously described, and do not appear to afford a measure of any clearly defined physical constant. The disruption of the glue in these tests is more nearly a shear than anything else; but in any case the results have been found in practice to be reasonably comparable.

The procedure adopted in carrying out the A. I. D. strength tests is as follows:

1 Test pieces. Consist of carefully selected pieces of hard, dry American walnut 2 in. wide by 9 in. long and $\frac{3}{8}$ in. thick. The flat 2 in. sides are planed true and slightly toothed with a fine smoothing plane. See Fig. 2.

2 Constant temperature. In order to obtain a constant temperature in both the wood and the glue solution under test, a constant-temperature oven, maintained at 35 deg. cent. or 95 deg. fahr., is employed. The wooden test pieces are allowed to remain in this oven for several hours before the test joint is made.

3 Preparation of glue solution. Following the maker's instructions, a weighed quantity of glue is soaked in the required volume of water at room temperature. When thoroughly soaked, which is usually in about 24 hr., the glue is heated in a water-jacketed pot to a temperature of 60 to 80 deg. cent. (140 to 175 deg. fahr.) for $\frac{1}{2}$ hr. The inner vessel or kettle of the glue pot

is then transferred to a constant-temperature oven maintained at 60 deg. cent. (140 deg. fahr.), and is allowed to stay there for about 1 hr., or long enough to bring its contents up to the temperature of the oven.

4 Preparation of test joints. Two pieces of the warm wood are then removed from the oven, and the glue is quickly applied to the faces to be joined, using a finger to spread the glue in order to avoid air bubbles. The two pieces are then pressed together so that they form a simple overlap joint 1 in. long and having a total glued area of 2 sq. in. The details of the joints are given in Fig. 2.

5 Number of test joints. Nine joints, made as above described, are prepared for each sample for glue to be tested. They are clamped for 12 hr. in hand presses, such as are ordinarily used in modern gluing practice. The pressure is then removed and the joints allowed to set for 24 hr. at room temperature.

6 Tests. Three tests are applied to these nine specimens, three being subjected to each of the following tests:

a Regular dry test. Three of the joints are broken in turn by clamping the two ends and pulling the component parts of the joint apart in a testing machine. It is necessary that the load be applied without jerks, and that bending of the test pieces be avoided as far as possible. The load is put on at the rate of about 3000 lb. per min., and the amount necessary to break the joint is recorded.

b Heat test. Three of the remaining six joints are then placed in an oven at 45 deg. cent., and are subjected to dry heat at this temperature for 72 hr., after which they are removed from the oven and broken as above.

c Immersion test. The remaining three joints are immersed for 3 hr. in water at 25 deg. cent. (77 deg. fahr.). On removal from the water they are broken as above.

The three sets of joints are broken on the same day in order that the results may be comparable.

Glues are classified in three divisions by the A. I. D., and in order for a glue to be put into one of these classes it must attain the following values in the tests:

Division.	Breaking point in tests, lb. per sq. in.		
	Regular test	Heat test	Immersion test
Propeller Class	1100	1100	900
Class I	1000	1000	800
Class II	900	900	700

It will be noticed that the best glues are thus retained for propeller work. Class I glues are sanctioned for all important construction exclusive of propellers, while the Class II material is approved for smaller and less important work.

In conducting the above tests it usually is found that the break occurs in the glue, but should the fracture be located wholly or partly in the wood, the result is discarded if the value obtained is below the minimum figure given above.

One other point deserves attention, namely, that the figures given in the table relate to the 2-sq.-in. test joint specified. A larger test joint would not show a proportionate increase in strength. For instance, if the area is doubled, the strength will be increased only about 50 per cent.

Grading of Glues

Interesting data are also presented on the subject of grading of glues, and also on their waterproof qualities. There are several methods of grading glues which, however, are entirely arbitrary. The oldest scheme in use in this country, and which is still generally employed, is the Cooper system, which was originated by Peter Cooper. No rational basis is used in grading glues by this method, the various Cooper grades representing simply those which were put out by Peter Cooper's glue factory, and which, being remarkably uniform, came to be adopted as standards of comparison. The Cooper grades are eleven in number, as follows: A extra, 1 extra, 1, 1X, $1\frac{1}{4}$, $1\frac{3}{8}$, $1\frac{1}{2}$, $1\frac{5}{8}$, $1\frac{3}{4}$, $1\frac{7}{8}$, 2. Of these, A extra is the strongest and 2 the weakest.

It is frequently found, however, in attempting to grade different glues by this system that there are varieties which are stronger than the A extra grade, and it is also evident that glues may be of almost any intermediate strength between the various Cooper grades. It is also a fact that a glue corresponding to one of these grades in gelatinizing power may agree with an entirely different rating in viscosity. There is in this respect a marked difference between bone glues and hide glues, and between acid-treated types and those not so treated. For instance, an acid-treated glue may rate as high as 1X in gelatinizing power and as low as $1\frac{3}{4}$ in viscosity. There are numerous discrepancies of this sort which must be taken into account by the glue tester, so that the rating of glue by this system is full of difficulties.

Relative Merits of Different Glues

The following data on the relative merits of different glues are also of considerable interest. No one best glue has so far been found, since very few records of systematic strength tests are available. Most types of glue suitably selected and manufactured can be made fairly water resistant.

The three kinds of glue suitable for use in airplane construction are the hide, casein and blood-albumen varieties. Of these only the casein and blood albumen types are satisfactory for plywood construction, as hide glue is not truly waterproof. Tests to date show that both these glues can be used to advantage, and it therefore seems advisable to allow plywood manufacturers to apply whichever preparation they prefer.

Since the latest Bureau of Aircraft Production specifications for plywood do not bar the use of any glue, it is very important that the soaking and baking tests be carefully made in order to detect the use of any non-waterproof or otherwise unsuitable glue which might show very great strength if not subjected to deteriorating conditions, but which would lack the necessary lasting qualities.

Hide glue has so far been very satisfactory for propeller construction, provided sufficient care be taken to properly guard against moisture and changes in atmospheric conditions. Casein glue may eventually prove more satisfactory for this use, however.

Blood-albumen glue is not altogether suitable for general work, except in the manufacture of plywood, on account of the care and expense necessary in its use, the hot presses and other costly equipment required, etc. Its high strength and waterproof qualities, however, make it excellent for laminated construction. Blood-albumen glue has been found to be even more water-resistant than the casein types.

For general airplane use, including splices in spars and longerons, plywood and built-up members, casein glue seems to offer the most advantages. It is nearly as strong as the best hide glues, while it is comparatively waterproof, is fairly easy to mix and apply, and is quite dependable if proper care is exercised.

The original paper contains a list of manufacturers of glues, with addresses, and a short bibliography on the subject.

LUBRICATION OF AIR COMPRESSORS

Satisfactory lubrication of air-compressor cylinders is attained by securing (1) the reduction of friction to a minimum and (2) elimination of carbonization of the oil as far as possible.

Carbonization of the oil allows the accumulation of deposits of carbon which are sticky in the early stages of their formation but hard and flinty later. Such deposits accumulate on the cylinder valves, in the cylinder passages, in the pipes and eventually in the air receiver.

Sticking or partial closing of the valves and their consequent failure to act properly is probably the chief objection to this action from the standpoint of the efficient operation of the compressor.

The formation of excessive carbon deposits is apt to be due to any one or more of the following causes:

[1] From a report prepared by H. V. Conrad, 30 Church Street, New York, Secretary of the Compressed Air Society, and issued by the Technical Committee of that society.

1 The ill-advised use of some oil, such as a steam-cylinder oil, which easily decomposes in the heat of the air cylinder.

2 The use of oils of too great a viscosity—commonly referred to as "too heavy oils." These do not atomize readily and, therefore, remain too long upon the hot cylinder walls, etc., thus baking down to sticky carbon deposits.

3 The use of too great quantities of oil, which has the same effect as the use of too heavy an oil as far as the carbonization is concerned.

4 The failure to provide a proper screen over the air intake of the compressor, thus allowing free entrance of dangerous dust (especially coal dust).

Heat of Air Compression. The selection of an air-cylinder lubricant, of course, is governed to a considerable extent by a knowledge of the cylinder temperature it must withstand. Knowing the air pressures, the corresponding temperatures are ascertained fairly accurately, as shown in Table 1. This table gives the final temperature in the cylinder at the end of the compression stroke, for single-stage, also for two-stage (or compound) compression, when the free air entering the cylinder is at 60 deg. fahr.

TABLE 1 CYLINDER TEMPERATURES AT END OF PISTON STROKE

Air Compressed to (pounds, gage)	Single-Stage, Final Temperature, deg. fahr.	Two-Stage, Final Temperature, deg. fahr.
10	145	. .
20	207	. . .
40	302	. . .
60	375	203
80	432	224
100	485	243
150	589	279
200	672	309
250	749	331

The natural inference after noting the temperatures in Table 1, is that an air-cylinder oil should be selected whose flash point is higher than the maximum temperature apt to be encountered within the air cylinder. As a matter of fact, this is not the case.

Qualities of Cylinder-Lubricating Oils. For average normal conditions, the oil should be a medium-bodied pure mineral oil of the highest quality, not compounded with fixed oils such as animal or vegetable, and should be carefully filtered in the final process of manufacture. A distinction must be made between those oils having a paraffin base as distinguished from those having an asphaltic base. Carbon deposited by the asphaltic-base oils is of a light, fluffy nature and easily cleaned out, whereas, that deposited by the paraffin base oil is very adhesive, and characterized by the hard, flinty nature.

Paraffin-Base Lubricating Oils. Merely as a guide to aid the operator in specifying the qualities to be possessed by an air-cylinder lubricant recommended for average duty, Table 2 is presented.

It is suggested that those oils within the range expressed by the minimum figures be used for light duty of low pressures and temperatures, while those expressed by maximum figures should be used for high pressures and temperatures.

It is recommended that any paraffin-base lubricant intended

TABLE 2 PHYSICAL TESTS OF PARAFFIN-BASE OILS

	Minimum	Average	Maximum
Gravity, Baumé ..	28 to 32 deg.	25 to 30 deg.	25 to 27 deg.
Flash Point, Open Cup...........	375 to 400 deg. fahr.	400 to 425 deg. fahr.	425 to 500 deg. fahr.
Fire.............	425 to 450 deg. fahr.	450 to 475 deg. fahr.	475 to 575 deg. fahr.
Viscosity (Saybolt) at 100 deg. fahr.	120 to 180 sec.	230 to 315 sec.	to 1500 sec.
Color............	Yellowish	Reddish	Dark Red to Green
Congealing Point (pour test, deg. fahr)...........	20 to 25 deg. fahr.	30 deg. fahr.	35 to 45 deg. fahr.

for use in "all standard air compressors," should meet the physical tests imposed by the average range of figures given in the middle column of Table 2. The above wording "standard air compressors" is to be interpreted as including the following types of machines:

a Low-pressure up to 100-lb. compressors, which may be either small-sized single-stage units, or larger-sized compound machines.

b High-pressure compressors which are constructed with the proper number of stages so that no excessive temperatures are ever reached.

In other words, this lubricant of average test figures is always recommended unless a compressor manufacturer specifies in his literature that a high-flash-point oil should be used to meet the conditions peculiar to his machine. It is thus obvious that it is never necessary that a lubricant should possess a flash point as high as 500 deg. unless abnormal conditions of high temperature prevail. Such high-flash-point oils have an unusual tendency to produce carbon deposits.

Asphaltic-Base Lubricating Oils. This group of oils is considered separately for the reason that the lower limit of gravity stated in Table 2, viz., 25 deg. Baumé, eliminates the entire group from consideration—which is not the intention. As a guide for the selection of suitable oil, Table 3 is given.

TABLE 3 PHYSICAL TESTS OF ASPHALTIC-BASE OILS

	Minimum	Average	Maximum
Gravity, Baumé...	20-22 deg. fahr.	19.8-21 deg. fahr.	19.5-20.5 deg. fahr.
Flash Point, Open Cup....	305-325 deg. fahr.	315-335 deg. fahr.	330-375 deg. fahr.
Fire.............	360-380 deg. fahr.	370-400 deg. fahr.	385-440 deg. fahr.
Viscosity (Saybolt) at 100 deg. fahr.	175-225 sec.	275-325 sec.	475-750 sec.
Color............	Pale Yellow	Pale Yellow	Pale Yellow
Congealing Point (pour test).....	0 deg. fahr.	0 deg. fahr.	0 deg. fahr.

Proper Quantity of Lubricating Oils. The quantity of lubricating oil to feed to the air cylinders of compressors cannot be stated in exact terms due to the varying viscosity of different oils, the heat of compression and the size of cylinder. It may be stated in general, however, that after the cylinders have acquired smooth and polished surfaces, the quantity should be reduced to the lowest limit to avoid the possibility of the accumulation of carbon and sooty deposits.

TABLE 4 QUANTITY OF AIR-CYLINDER LUBRICANT REQUIRED PER 10-HOUR DAY

Diameter of Cylinder, Inches	Size of Cylinder, Inches	Displacement per Minute, Cubic Feet	Piston Speed, Feet Per Minute	Sq. Ft. of Cylinder Wall Swept by Piston	Drops Oil per Minute	Drops Oil per 10 Hr.	Sq. Ft. Oiled Per Drop	Number Pints Oil Required Per 10 Hr
8	8 x 8	120	344	718	1	600	718	0.0375
12	12 x 12	320	408	1230	2	1200	613	0.0750
18	18 x 18	880	496	2340	4	2400	585	0.1500
24	24 x 24	1730	550	3450	6	3600	575	0.2250
30	30 x 30	2940	600	4700	8	4800	590	0.3000
36	36 x 36	4550	644	6070	10	6000	607	0.3750
42	42 x 42	6700	696	7600	12	7200	633	0.4500

Figures of last column are based upon an estimated 16,000 drops per pint of oil at 75 deg. fahr.

The basis of quantity given in Table 4 is recommended, subject to above modifications for these cylinders or equivalent sizes, operating under normal conditions.

A leading authority on compressor engineering contributes the following: "The best way to determine the proper amount of lubrication is to take out the valves from time to time and examine the cylinder. All parts should feel that there is oil thereon. If they feel dry, the lubricators should be adjusted to feed a little

more oil, whereas if oil lies in the cylinder and its parts show excessive oil thereon, the quantity fed by the lubricators should be reduced. By thus examining the machine a few times, the proper amount of oil can be determined to suit the characteristics of the particular lubricant used and the conditions under which the machine operates." This is a better way to finally determine the quantity of oil required than by adopting without this experimenting any tabulated number of drops.

BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in THE JOURNAL, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 208-214, inclusive, as formulated at the meeting of January 17, 1919, and approved by the Council. In this report, as previously, the names of inquirers have been omitted.

CASE NO. 205

Inquiry: An interpretation is requested of the distinction between the term *staybolt* and the terms *stay* and *brace* as used in the A.S.M.E. Boiler Code. Under what conditions may a reinforcing member be considered a *staybolt*, or a *stay* or *brace?*

Reply: The term "staybolt" as used in the Boiler Code refers to a bolt screwed through the plate or plates, with the ends of the bolt riveted over or fitted with nuts.

CASE NO. 207

Inquiry: Is it the intention of the Boiler Code Committee that in the application of Par. 214, item (1) means that the radius of the flange is not to exceed eight times the thickness of the head, or that *d* is so limited while the radius may be as large as desired?

Reply: It is the intention of the Committee that the restriction implied in Par. 214 shall apply only to item (1).

CASE NO. 208

Inquiry: Is it permissible under the requirements of the Boiler Code to use extra heavy steel pipe for superheater drum of a header type boiler, this pipe drum being connected to a steam drum by tubes which form part of the boiler heating surface?

Reply: Under the requirements of Pars. 9 and 11, the header or drum under discussion must be of wrought steel or cast steel of class B Grade. It is the opinion of the Committee that the words "wrought steel" in these paragraphs, mean wrought steel in accordance with one or the other of the specifications for various classes of wrought steel that are incorporated in the Code.

CASE NO. 209

Inquiry: If it becomes necessary to change the setting of a safety valve by putting in a new spring, what is the procedure necessary in connection with the marking on the body of the valve? Also in the case of a boiler whose total safety-valve area exceeds that of the orifice of the nozzle by 25 per cent, is it necessary to put on a larger nozzle to accommodate this safety-valve capacity? The owner points out that if they could substitute flat-seated valves, the present nozzles would be amply large.

Reply: If a safety valve is fitted with a new spring which changes its relieving capacity, it is the opinion of the Committee that it should be considered as a new valve which will necessitate remarking. In the case of two safety valves whose total area exceeds that of the nozzle by 25 per cent, it should be understood that if this applies to the case of an existing installation, the requirement of Par. 278 of the Boiler Code is not applicable; to a new installation, on the other hand, the requirement of Par. 278 is applicable and cannot be modified.

CASE NO. 210

Inquiry: An interpretation is requested of Par. 328 of the Boiler Code with regard to its applicability to soot-blower doors in the settings of water-tube boilers where the doors are made 8 by 8 in. in size and are seldom located less than 10 or 12 ft. from the floor.

Reply: In specifying latching devices for firing doors, furnace inspection doors and clinker doors in Par. 328, it was the intent of the Boiler Code Committee that all outward-opening doors, excepting explosion doors, shall be latched, unless they are so located that the attendant will not be injured by an explosion of the gases or tubes within the boiler setting.

CASE NO. 211

Inquiry: Is it the intent of Par. 277 of the Boiler Code to prevent the use of a connection to a spool or Y-pipe between the boiler and the safety valve for supplying steam to soot blowers which are subject to only occasional use? It is pointed out that such a connection would avoid an extra opening in the steam drum.

Reply: It is the opinion of the Boiler Code Committee that there should be no auxiliary connection of any sort made to the fitting between the boiler and a safety valve, if there be any such fitting.

CASE NO. 212

Inquiry: An interpretation of Par. 274 is requested which will show whether the safety valves should be proportioned with capacities as rated in Table 8 (Table 15, Edition of 1918) to relieve the total steam generated by the boiler, or of an arbitrary rating per sq. ft. of heating surface.

Reply: The sizes of safety valves should be determined on the basis of the total relieving capacity, the minimum value of which is to be determined in accordance with Par. 274 and on the basis of the relieving capacity of the safety valves stamped thereon by the manufacturer. Table 8 (Table 15, Edition of 1918) does not govern the relieving capacity of safety valves, but simply shows the computed relieving capacity for various lifts of safety valves. There is no limit set in the Code to the amount the safety valve may lift, provided the valve operates properly, and it may be that the relieving capacity stamped on the valve by the manufacturer will be greater than any of those given in Table 15.

CASE NO. 213

Inquiry: Can vertical tubular boilers up to 54 in. in diameter which are built of flange steel with punched rivet holes, drilled tube holes and cast-iron fire-door ring and mud ring, be stamped under the A.S.M.E. Boiler Code standard when the operating pressure does not exceed 50 lb.?

Reply: The boilers referred to in the inquiry, if used as steam boilers, may carry 15 lb. pressure as a maximum under Par. 338 of the Boiler Code, or if used as hot water boilers, may carry 50 lb. pressure as a maximum under Par. 335*a* and *b*. If, as steam boilers, they carry more than 15 lb. pressure or as hot water boilers, they carry more than 50 lb. pressure, they must conform to the Rules for Power Boilers.

CASE NO. 214

Inquiry: In the case of a gas-fired vertical-tubular boiler which is so encased that the products of combustion pass outside of the shell as well as through the tubes, is it permissible under Par. 430*d* and *e* to locate the fusible plug in the outside shell?

Reply: The fusible plug may be placed in the shell of a boiler of this type where the hot gases pass around the shell, provided the height of the plug corresponds to that it would occupy if placed in the tube as specified in Par. 430*d*.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of MECHANICAL ENGINEERING by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

Improvements in Locomotive Boilers

TO THE EDITOR:

In the Engineering Survey Section of MECHANICAL ENGINEERING for March, pages 284 and 285, I notice a description of certain improvements in locomotive boilers which were recently tried out on the Chicago, Milwaukee and St. Paul Railroad by Mr. Nicholson. As I have been a designer and constructor of all kinds of boilers for a great number of years, as well as the designer and builder of tools for making boilers—having equipped practically two-thirds of the boiler shops in the United States with my tools—I am sufficiently interested in the subject-matter of the abstract in question to submit the following comments:

1 Pockets in fireboxes are not new, but their connection with the leg of the boiler, where all the mud and dirt is supposed to collect, is a new idea. Presumably this has been suggested by the arch tubes which have been placed in boilers with a view of improving circulation and for accommodating the brick arches. This connection, I believe, will prove difficult and costly to maintain.

2 Locomotive boilers some years ago were very much smaller than they are today, and their present abnormal size makes it very difficult to control expansion and contraction, two great evils in connection with rigid firebox construction which railroad men have been trying to control with flexible stays instead of flexible fireboxes.

3 The desirability of placing obstacles in fireboxes to save fuel is questionable, and the fact that the construction described is installed where the heat in the firebox is greatest proves how valuable firebox heating surface is. The application of this idea requires a construction of greater rigidity than that of the ordinary firebox, and rigidity, it is agreed by all boiler experts and engineers, is the cause of all the troubles in fireboxes. It is also to be noted that a greater number of stays have been added to the firebox, which, I may state, is very undesirable.

Should this arrangement be generally adopted, I predict it will prove a very costly experiment to the railroads; the Government is not warranted in allowing such ideas to be made to appear practical when it is known by experts that the advantages it affords are obtainable only at the expense of its upkeep. It is well known, too, that the locomotive is already loaded up with more improvements than the upkeep warrants.

Labor Dilution as a National Necessity

TO THE EDITOR:

The Great War has been the means of educating the masses in things that are vital to the nation, and of the many important projects which have come to our attention, the training of semi-skilled and unskilled labor in the arts of manufacturing has become a necessity that all are bound to recognize.

Before the War very few manufacturers had any idea of the meaning of Labor Dilution. What does this Labor Dilution mean? In so many words it means the utilization of the army of misfits into productive industrial units. Except as applied to female workers, Labor Dilution has hardly had a fair start, notwithstanding the immense amount of constructive work that has been done through the Army and Navy instruction centers.

The Curtiss Aeroplane and Motor Corporation was one of the first to appreciate the value of maintaining a school for the purpose of training our female workers on exactly the same operation they would be expected to perform in the production departments. The success of this work is evident to all employers who have recently used women on operations formerly performed by male labor. They have made good, and it is the universal opinion that on many jobs women are better than men.

Will industry, now that it understands what results can be accomplished by Labor Dilution, revert to the old state of affairs? I think not. We have been accustomed to measure our needs by the other fellow's experience, but now it is plain to us it is not necessary to strive for the high standards of mechanical ability we have heretofore demanded.

For years we have overlooked a valuable source of labor supply right at our doors simply because we had no means of utilizing their labor. We have neglected to study the mental progress of semi-skilled and unskilled laborers. We have, without thinking, assigned them to the laboring positions, never giving them the benefit of an ambition to aspire for advancement.

During the past year our experience has been that men who formally applied for laboring positions were asking for machine jobs. In questioning them we found they had no special experience to qualify them for the important positions, and the result was that many of them were turned away. However, in the aeroplane business it was not possible for us to draw from an available supply of expert aeroplane mechanics, and there were operations where we could take some of the brightest applicants and place them on work where they could, in a short time, master the details.

In looking back we recollect with amazement the avidity these men and women displayed when they were given a chance to break the bonds which held them in check. They have played an important part in the battle for liberty because they themselves have become liberated, and now that the war is over, are they to become an industrial asset or liability?

These men and women have had the benefit of specialized industrial training, and while they are not full-fledged mechanics, they are, nevertheless, better equipped to qualify for industrial work. The next question is, Are they going to be able to capitalize their experience? Naturally one would say, "Yes, if they can find the same class of work." I do not think this has any bearing in the case, because these people have demonstrated to their own satisfaction that if they can learn one job they can learn another. If this is not true, then is not all the study and work that has been put into labor dilution been in vain?

The force of habit in some concerns is bound to manifest itself in the readjusting period now before us. They are going to cast about for the high-grade skilled mechanic in the thought that they are going to beat their competitors in the rush for peacetime business. The wise manufacturer, however, will "father" the idea of building an organization of operators which can be very easily developed by intensive training methods.

For instance, large employers of labor throughout the country, who, for the past year or more, have spent a lot of time and money on intensive training, are not going to set this all aside and proceed to hire and train their operators by the old methods. It is not necessary to prove to them how much it costs to replace workmen taken into the shop and turned over to a foreman on production work for instructions under the old system. This is by far the most expensive way, figuring it from all angles.

In the Curtiss Aeroplane and Motor Corporation we have found that it costs, on an average for a three months' period, \$34.27 to

train a girl or woman for production work. It is reasonable to assume that if the worker was placed in the shop without going through the training department, the cost would be two or three times as much.

The soldiers and sailors who have been trained intensively in the various technical schools and manufacturing plants throughout the country, are they going back to their old line of endeavor, or are they going to follow the work in which they have been instructed? Again the theory of labor dilution must be upheld or else the efforts which have been put forth to train these men have been wasted.

For example, the Navy has periodically sent batches of men to our plant to receive intensive training in the construction of flying boats. Many of these men never had a woodworking tool in their hands before, but in a short time were able to perform a very creditable job, so much so that they were able to make all necessary repairs without outside assistance.

These men have received a training they never would have acquired under normal conditions. They have "found" themselves and are not going back to the old pursuits. Industrially these men are an asset, and as such we are duty bound to provide them a means of livelihood.

The part that organized labor will play in this scheme must necessarily wait developments, but we must not overlook the fact that Samuel Gompers, President of the American Federation of Labor, is the motive power which called into being the committee on Training and Dilution, responsible for the propaganda of specialized industrial training.

Even before the war employment managers were unanimous in the statement that there was a shortage of qualified mechanics. Manufacturers and employers of labor generally were responsible for this state of affairs, because when there was a mechanical position to be filled they demanded an A1 man for the job. We had long since given up the practice of the indentured apprenticeship, and it was not so much the question of where the man received his training as it was to get the right man. The idea of doing their part in replacing and developing the inevitable loss of expert mechanics due to old age and death did not concern them until the war came, and their best men either enlisted or were drafted into the Army and Navy. It was then the necessity of labor dilution manifested itself. Industry and the workers have benefited by the introduction of intensive training methods, and it is not reasonable to suppose they are going to turn their backs on a system which has enabled the Government to provide the sinews of war. We have taken a step forward which does not permit retraction.

CHARLES E. FOUHY,
Employment Manager,
Curtiss Aeroplane and Motor Corporation.

Buffalo, N. Y.

Industrial Service Education

TO THE EDITOR:

At the Thirty-ninth Annual Meeting of The American Society of Mechanical Engineers, Mr. D. R. Kennedy, Employment Manager of the American International Shipbuilding Corporation, expressed in a splendid way the changed conditions in industry as follows:

"Permit me to prophesy that the executive of the next decade will be the man who best knows men. He will be an organizer, a handler of men as individuals, a handler of men in the mass, a leader, not a driver; a very human man. The science of human engineering is here to stay. The study of human characteristics is the most enduring, as well as the most fascinating, in the world, and still the most complex."

The big question is, How are we to develop this new type of engineer, manager, employer, business executive? Some of these men will be self-made. A large proportion of them will probably come from among the graduates of our engineering schools and colleges. This raises the really fundamental question. To what extent are our engineering colleges giving the type of instruction which will tend to build this new type of executive? It is encouraging to see that, from a rather comprehensive study of practically all the important engineering colleges of the country, many of these are beginning to readapt their curricula to include more on the human side of the job. Much more of this must be done. A thorough investigation of engineering education made by C. R. Mann, of the Carnegie Foundation for the Advancement of Teaching, revealed clearly this need. The Industrial Service Movement of the Young Men's Christian Association has been responsible for a suggested college course on the Human Side of Engineering, which includes such studies as the following: The Human Factor in Industry, Human Factors in Production, The Ethics of Engineering and Business, Employment Management, Vocational Guidance, Scientific Management in Its Human Relations, The Engineers' Responsibility for Service, and Industrial and Social Readjustment and Reconstruction. (Copies of this course and bibliography will be furnished on request.) Already a number of leading institutions have adopted this, or a similar course, in whole or in part.

Remarkable results have attended such courses wherever given, but even this is not enough. With this fact in mind, the Y. M. C. A. has, for over ten years, been promoting a thoroughly comprehensive scheme for the education of our coming engineers in the human side of their work. In addition to counseling with leading employers, labor men, engineers and professors throughout the country, and suggesting helpful courses of study, the organization has worked out, in its Industrial Service Movement, helpful lists of lecturers, lists of books and welfare literature, a series of pamphlets intended to inspire the engineering student and graduate along lines of industrial betterment and service, etc. The movement has enlisted as many as 4500 college students from over 250 engineering schools and universities, in fifty varieties of worth-while service with working men and boys. About 2000 of these students have taught classes in English, citizenship and Americanization. Approximately 1000 others have led technical classes and taken charge of other lines of work with American workingmen, and the rest have been helping with boys' clubs and other forms of constructive endeavor among working boys and apprentices. The amount of actual service rendered has been extraordinary, and 100,000 industrial workers have been reached. The quality of the service has been surprisingly high, and the appreciation of the men served very great. Needless to say, however, the students themselves have gained far more then they have given. They have inevitably come to understand actual industrial conditions and the problem of handling men whom they will be obliged to handle after graduation. Their practical service has given them a sympathy and understanding which could be gained in no other way.

Under normal conditions our colleges are graduating approximately a thousand men a year who have had a real touch with this movement, and who, from all probability, scatter throughout the industrial world into larger spheres of influence. Whatever their occupations, they will never cease to be human engineers. This is the big objective. It will be these men, and others like them, together with many of our returned soldiers, upon whom the burdens of industrial and social reconstruction will fall.

FRED H. RINDGE, JR.

347 Madison Avenue, New York.

In a pamphlet on International Control of Minerals recently issued by the U. S. Geological Survey, the strategic position of the United States is graphically shown by a table compiled by Dr. C. K. Leith. The United States controls about one-third of the world's mineral production of 1,700,000,000 tons. The few minerals for which this country is dependent on foreign countries are offset by so many in which we have a dominance of supply and our financial position is so strong that it appears certain that in this respect our entrance into a league of nations would not be based on self-interest. The interests of conservation clearly require an international control of minerals; whether the time has come to establish a league of nations with economic control, he says, can be determined only by the collective answers to the question of whether the nations are willing to make the necessary economic sacrifices in the interest of world harmony.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

AERONAUTICS

Balancing Aeroplane Propellers (Baudisch, *Der Motorwagen,* December 20, 1918). A perfectly balanced propeller has its center of gravity exactly on the center line of the propeller shaft on which it rotates. In practice, although the propellers are made out of wood, as homogenous as possible, and the two blades are nearly identical as can be attained, one blade is invariably heavier than the other.

The balancing of the propeller to make the center of gravity of the propeller coincide with the center of gravity of the propeller shaft can be done either statically or dynamically. The method of procedure for the static balance only requires simple appliances, but is very tedious and slow to carry out.

The dynamic balance can be done much more quickly, but it requires a rather complicated and expensive balancing machine, and in consequence the static method is in more general use than the dynamic.

The author proceeds to explain a dynamical balancing process built up on the same principles as the statistical method, which is such that while the results are as exact as those obtained statically, it has the great advantage of being rapid in execution. An additional point is that the apparatus required is as simple as that for the static test.

The propeller is fitted to a horizontal testing axle, which rotates on ball or roller bearings so that it is as frictionless as possible. The bearings are rigidly mounted sufficiently high above the floor level to allow the propeller to rotate freely. If the propeller be left to itself it will after several vibrations, come to rest with the center of gravity in its lowest position. The weight which must be added to obtain the true balance can be obtained mathematically by following out a simple system of calculation given by the author, the data for which are gained from the results obtained by fixing known weights both above and below the propeller center, at different given distances.

The article is concluded by some hints on errors to be avoided in making the tests, such as insuring that the testing axle has no bend in it through the weight of the propeller, that the propeller does not slip on the axle, and that the bearings on which it runs are perfectly rigid. (*Technical Supplement to the Review of the Foreign Press,* vol. 3, no 4, Feb. 18, 1919, pp. 128-129, no. 4308)

AIR MACHINERY (See Heating and Ventilation)

ENGINEERING MATERIALS

Toughness: Its Nature and Measurement

Static, Dynamic and Notch Toughness. According to the author, the point of view presented in the paper here abstracted is that toughness, like hardness or tensile strength, should be regarded as an independent property and of sufficient importance to require, in so far as that may be possible, quantitative determinations. If so, it becomes necessary to devise experimental means for measuring or valuating toughness and the notched-bar impact

Fig. 1 Left Side of Keyseat

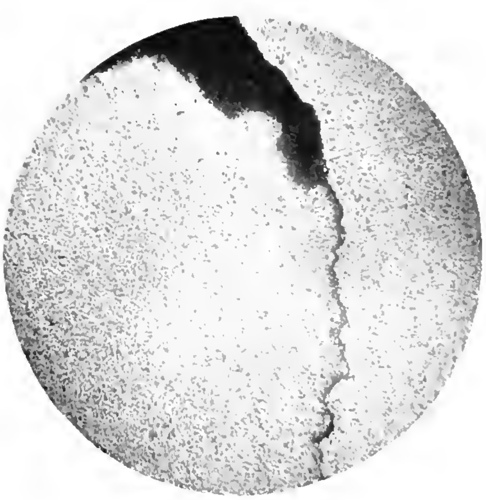

Fig. 2 Right Side of Keyseat

test or the Charpy test is advanced as the most logical test that has so far been developed for this purpose. It is also claimed that there are two kinds of toughness, which have to be dealt with independently.

Tough materials have been defined as those that offer consider-

able resistance to permanent deformation, but which, once resistance has been overcome, may be deformed plastically, though only by the expenditure of considerable energy. In other words, tough materials may be deformed plastically, but they absorb a considerable amount of work in the process. This kind of toughness may be called "static" when the rate of loading is reasonably slow, or "dynamic" when the rate of loading is comparatively rapid, as in the impact test. In all cases the stress distribution is essentially uniform, but static toughness does not imply resistance to shock, or dynamic toughness; and dynamic toughness may be equal to, greater than, or less than static toughness, a fact illustrated by numerous cases on record.

In addition to the foregoing there is what the writer calls "notch toughness," defined as the ability of a material to withstand stresses when in the notched condition. (It is a well-known fact that if the change in cross-section is in the form of a nick or a groove, the strains at the base of the nick multiply and are much greater than the average strain over the cross-section.)

Attention is called to the fact that the notch effect is quite frequently met with in engineering practice. At times it may be intentionally introduced through the design of the part, sometimes faulty, and at times may be unintentionally introduced through faulty or careless workmanship. It is also important to consider the microstructure and the desirability of heat treatment as a means of overcoming or counteracting the effect of the notch.

Several examples showing the danger of the presence of notches in various forms are considered, among others being the danger of a keyseat in an axle. Photomicrographs, Figs. 1 and 2, are given showing the extensions of two cracks leading from the angles of the keyseat. If it is necessary to use such a keyseat, the material should be suitably heat-treated to give a high notch toughness, or better, perhaps, both the material and the heat treatment should be selected with reference to its notch toughness.

The writer recommends that a notched-bar test should supplement the usual tensile and hardness test and its results be used as an index of the resistance of the material to the notch effect.

Objection has been raised to the adoption of such a test on the basis of lack of uniformity of results. In a number of cases the results of the notched-bar impact test are not as concordant as might be desired, but it is the opinion of many experimenters that variations in the impact resistance of supposedly similar test bars are due to actual variations in the material. The truth of this contention is demonstrated by the recent work of Charpy and Cornu-Thênard, who, by using exceptionally uniform and homogeneous bars, secured check results as close as 1 to 2 per cent and scarcely ever varying as much as 4 per cent. The results obtained by the commission of the German Society for Testing Materials were sufficiently concordant to lead to the adoption of the test and the minor variations were not permitted to mask the fact that the notched-bar test is capable of yielding valuable information that the tensile strength does not.

The writer is informed that at least one steel plant, which has done considerable work on the notched-bar test including the Charpy test, has found the concordance of results to be very satisfactory and capable of yielding possible differences of impact resistance of the order of magnitude of 1:30. Thus, it would seem that lack of concordance can now no longer be advanced as an objection to the adoption of the Charpy test. (*Bulletin of the American Institute of Mining Engineers*, no. 146, Feb. 1919, pp. 339-351, 10 figs., *cpA*)

TESTS ON CONCRETE (*Beton und Eisen*, December 4, 1918). Concrete test pieces (8-in. cubes) for the purpose of ascertaining safe crushing loads were prepared in porous and alternatively in iron molds. Those from the latter proved much inferior to the former.

The Government Testing Station in Berlin-Lichterfelde has therefore proposed that test pieces should be prepared in porous molds. Wooden molds were found unsatisfactory, as they did not retain their shape, but plaster-of-paris molds gave good results.

Test pieces prepared from one volume of cement and four volumes of carefully graded conglomerate mixed with 12 per cent of water failed under a pressure of 3400 lb. per sq. in. when made in plaster molds, and under 2235 lb. when made in iron molds, thus showing an increase of strength of 54 per cent in favor of porous molds. Similarly, one part of cement to six of conglomerate failed under 2025 and 970 lb. per sq. in., respectively, showing an increase in strength of 107 per cent. A large number of test pieces have been prepared in molds of iron, wood and plaster of paris, and it has been conclusively proved that the latter are the most reliable, and produce results closely approximating those obtained from test pieces cut out of actual work.

The German Concrete Institute has therefore framed the following regulations:

1 Iron molds as generally used for concrete are unsuitable for concrete grout because water is retained in the concrete and reduces the strength.

2 Molds of wood saturated with oil are also unsuitable. Molds of porous wood give satisfactory results, but must not be used more than five or six times, as they soon become saturated.

3 Plaster-of-Paris molds give test pieces that correspond closely to concrete found in structures. Each side of the plates may be used four or five times without losing the power to absorb water. They are cheap, and large numbers can be made simultaneously. The values found for crushing loads are reliable, and the progress of solidification is regular and in definite proportion to test pieces made in iron molds. (*Technical Supplement to the Review of the Foreign Press*, vol. 3, no. 4, Feb. 18, 1919, p. 109, no. 4192, *e*)

DEFINITIONS OF CEMENT (*Zeitschrift für angewandte Chemie*, December 3, 1918). The short descriptive word "cement" is usually understood to mean portland cement, composed of hydraulic lime and sand. But recently other substances have been substituted for the sand, so that some wider definition is required. In Germany the three now much-used types are thus defined: (1) Portland cement, consisting of a hydraulic binding substance, with less than 1.7 parts to one by weight of soluble silica, plus clay and oxide of iron: and manufactured by fine grinding and intimate mixing, burning, and again grinding; (2) ferro-portland cement, a hydraulic binding substance, consisting of at least 70 per cent portland cement and at most 30 per cent of blast-furnace slag; and (3) blast-furnace cement, a hydraulic binding substance, which, with a portland-cement content of not less than 15 per cent, consists mainly of blast-furnace slag, which, by sudden cooling of the molten mass, is converted into the granular form. (*Technical Supplement to the Review of the Foreign Press*, vol. 3, no. 4, Feb. 18, 1919, p. 109, no. 4191, *t*)

HEATING AND VENTILATION

Ventilating Fan with Air-Reversing Arrangement

MINE VENTILATING PLANT. Description of a British mine-ventilating-plant installation with an engine of 300 b.hp. The most interesting features are the general arrangement at the air end and the connection between the engine and the fan.

At the fan end of the crankshaft there is a flange forged on solid to which a small flywheel is bolted. The latter forms part of a flexible coupling (Fig. 3) which acts as a driving medium for the fan. On the fanshaft there is another similar wheel and between these two wheels there is a fanshaft about 2 ft. 6 in. over all with a flange forged solid on each end. On these flanges are bolted two steel plates which, near their outer peripheries, are bolted to the two flywheels. The arrangement forms a flexible coupling and the reason for employing it is to provide for any slight settlement such as sometimes occurs on a colliery pit bank and might, if not allowed for, cause trouble with the bearings.

A special arrangement shown in Fig. 4 is provided by which the air instead of being abstracted from the mine and discharged into the atmosphere may be driven in the reverse direction. In the left-hand view of the figure the plan is shown sucking air from the mine and delivering it to the atmosphere through the discharge opening or evasee. In order to reverse the direction of flow the discharge door shown at the bottom of the evasee and

counterbalanced by a cord and weight is drawn up so as to close the orifice at the base of the evasee, as shown in the right-hand view of the illustration. At the same time inlet doors in the casing (shown in the plan views at the bottom) are swung from the position shown in the left-hand view into that shown in the right-hand view which has two effects. It closes the passage leading to the inlet from the line shaft and opens the fan section to atmosphere. Then since the air cannot be discharged through the evasee, it is forced by the fan through the opening leading to a discharge passage into the mine which has been uncovered by

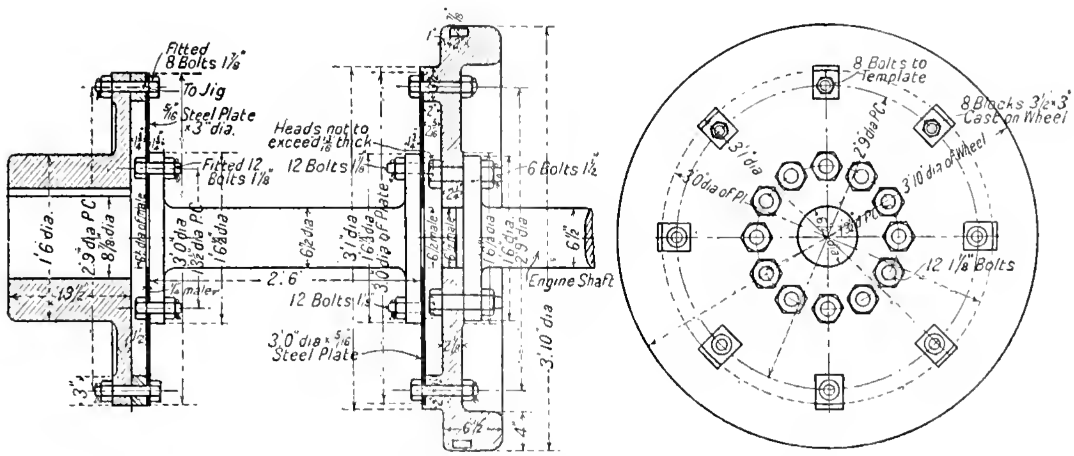

Fig. 3 Flexible Coupling between Engine and Fan

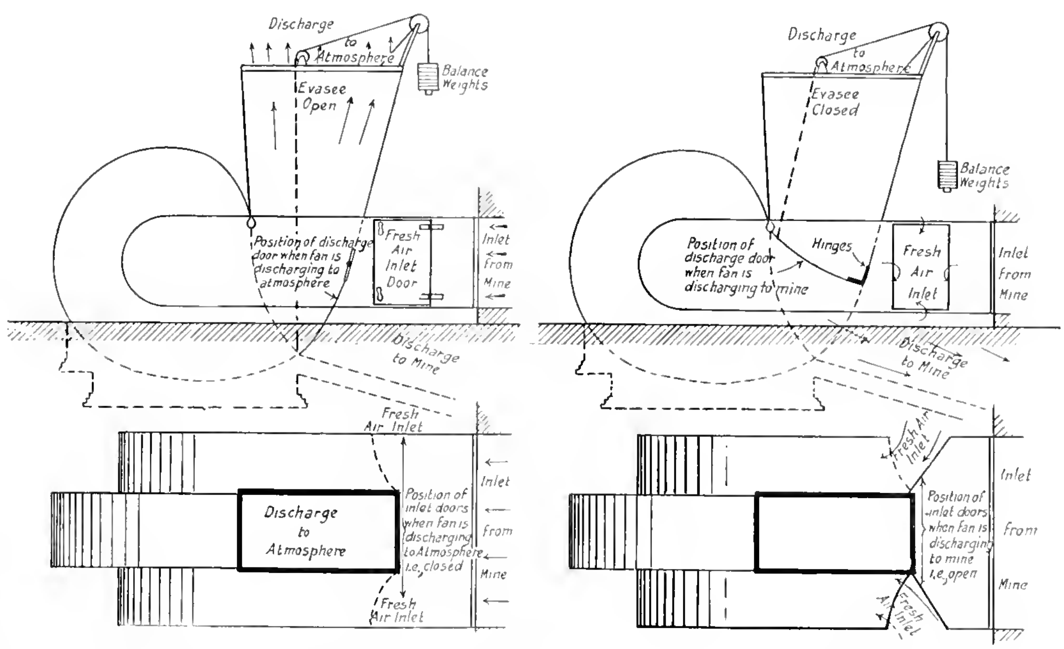

Fig. 4 Arrangement for Changing Direction of Flow of Air in a Mine-Ventilating Plant

the raising of the discharge door. It is stated that the necessary changes to bring about these reversals can be effected without stopping the engine it being only necessary simply to slow the fan slightly. (*The Engineer,* vol. 127, no. 3292, Jan. 31, 1919, pp. 110-111, 6 figs., *d*)

HEAT-TREATING

Hardening and Tempering Certain Railway Materials (*Stahl und Eisen,* December 5, 1918). G. Schultz, in *Organ,* describes the hardening processes to which keys, bolts, brake rods, parts of springs, screw nuts, valves and other moving parts of railway rolling stock are subjected. For all such parts basic Martin steel with at most 0.12 per cent carbon is used. The pieces are packed in the usual way into sheet-iron boxes, in which the surfaces to be hardened are in close contact with some hardening material. The closed and airtight boxes are kept, according to the thickness of the hardened outer skin required, from 10 to 18 hours in a muffle furnace at a temperature of 900 to 1000 deg. cent. Pieces, of which only a portion is to be hardened, are so packed that only those surfaces which are to be acted upon are in contact with the hardening materials, while the other portions are protected by some ready means. When the heating has been sufficient, the pieces are taken out and cleaned with a wire brush, and while still at a good red heat quenched in cold water. This gives a very hard skin; but, as a consequence of the long heating, leaves the metal coarse-grained and brittle. The quality of this hardened skin is greatly improved by a second heating at 800 deg. and quenching. By this process a fine grain is produced, and increased tensile strength is given to the hardened zone. In the case of important parts of the valve connection of locomotives, the good effect may be increased by several repetitions of the process. The duration of the repeat heats is from 15 to 90 min., according to the sectional dimensions of the piece. Such parts, as cranks and crankpins, which require long heating, are protected from burning by a thin covering of the hardening powder in an asbestos envelope. (*Technical Supplement to the Review of the Foreign Press,* vol. 3, no. 4, Feb. 18, 1919, pp. 112-113, no. 4213, *p*)

HYDRAULIC ENGINEERING

Single-Wheel Compound Water Turbines and Multi-Stage Centrifugal Pumps. H. Baudisch. (*Zeits. ges. Turbinenwesen*, 1 and 2, 1918. *Elektrot. u. Maschinenbau*, 36, p. 422, Sept. 15, 1918). Very narrow Francis turbines yield unsatisfactory efficiency. The lower limit of runner-wheel entrance breadth to runner-wheel entrance diameter is from 1/15 to 1/20, corresponding to a specific speed of about 60 r.p.m. There is a range of applicability of the Francis slow runner and that of the free-jet high-speed runner, the highest specific speed of which with single nozzle is about 35 r.p.m. This gap is filled by the Pfarr compound turbine in which water flows in series through several runners on one shaft. It is claimed that better results can be obtained at lower capital cost by allowing the water to flow twice or more through the same wheel. The guide and outlet chamber are divided into two equal parts. Half of the guide equipment is connected to the high-pressure pipe and half of the outlet chamber to the turbine suction pipe; the second half of the outlet chamber is connected to the second half of the guides. This single-wheel compound turbine has 100 per cent higher specific water volume than the Pfarr turbine and the same specific speed. It can be built as an axial or radial turbine or as a combination type; it can also be built as a spiral turbine with the spiral for each stage over one-half of the runner wheel. The use of a double-sided outlet on the runner wheel overcomes the axial thrust of the axial-radial turbine. Taking the lower limit of the specific speed of a runner wheel to be 60 r.p.m., the specific speed of the Pfarr compound turbine is 35.7 r.p.m., of the single-wheel compound turbine, 25.2 r.p.m.; and of the single-wheel, double-sided-outlet compound turbine, 35.7 r.p.m. Certain conditions which must be fulfilled by the single-wheel compound turbine, particularly in respect to pulsation, are noted in the original. The converse of the single-wheel compound turbine is the single-wheel multi-stage centrifugal pump. Both of these machines are of special importance where low capital cost rather than maximum efficiency is the primary consideration. Also, space is saved by the reduced axial length. (*Science Abstracts*, Section B—Electrical Engineering, vol. 22, pt. 1 (no. 253), Jan. 31, 1919, p. 8. *e*)

INTERNAL-COMBUSTION ENGINEERING

Performance of Marine Diesel Engines

Tests of Merchant-Ship-Type Diesel Engines. Data of official trials of two 1200-i.hp. (750-b.hp.) Diesel engines built by J. Samuel White & Co. for the British Admiralty. The trials were carried out in accordance with the special requirements of the British naval authorities and in the presence of their representatives.

The engines are direct reversible, two-cycle, single-acting, stepped-piston type, six-cylinder, 14½ in. bore by 24 in. stroke, and have a weight complete of 70¾ long tons.

The trials of the first engine consisted of 96 hr. of uninterrupted running at the full load of 750 b.hp. at a speed of about 200 r.p.m.

During the whole trial the engine ran satisfactorily without any stoppage and without any sign of overheating either in the cooling system or working parts. The exhaust was quite invisible and very little soot was observed after the completion of the trial. The temperatures at the end of the trial were practically the same as those attained at the end of the first hour.

The circulating water was passed through the engine by steam pumps, the quantity per brake horsepower being approximately 11.2 gal.

Additional maneuvering trials were carried out with the port engine consisting of astern running, time taken to pump up the starting reservoirs, slow-speed running and the drop in pressure of the starting air after each start.

Table 1 is representative of the results obtained in the 96-hr. trial of the starboard engine, while Table 2 gives data on lubrication and also the heat balance of the engine. (*Motorship*, vol. 4, no. 3, March 1919, pp. 17-20, illustrated. *eA*)

MACHINE DESIGN

Tests on Crankshaft Lubrication

Intermittent-Oil-Feed Investigation. Data of tests intended to determine the relations between quantity, pressure and seepage in bearings under various operating conditions, and a description of a special testing apparatus set up at McCook Field, Dayton, Ohio, for the present work.

The general appearance of the testing apparatus is indicated in Figs. 5 and 6. Essentially, the apparatus consists of a section of shaft of the same size as the main-bearing portion of the Liberty-12 crankshaft and mounted in a special test bearing with various sizes of inlet and outlet, as well as provision for driving the shaft and for making various measurements. The shaft used in most of the tests was 2⅝ in. in external diameter with a 1¼-in. hole drilled through its center, except at the driven end, which was left solid. The bearing housing consists of a special casting with bearing liner of standard construction. On one side there are four oil inlets A, B, C and D, Fig. 6, and opposite to these but staggered with relation to them, there are four outlets A_1, B_1, C_1 and D_1, all equipped with individual stopcocks so that any combination of the inlet and outlet sizes can be used and proper arrangements made for measuring the flow as to quantity (tank F), pressure (inlet gage J and outlet gage L), and

temperature (inlet thermometer N and outlet thermometer P).

In addition to the four side outlets there is an end outlet, shown at E, which takes the oil direct from the center of the hollow shaft and delivers it to a drainage tank I in which the quantity passing through the center of the shaft can be measured. The thermometer O indicates the temperature at this outlet.

The inlet connection M on the top of the test bearing is used in experiments to determine seepage along the length of the bearing. This inlet is located approximately one-third of the length of the shaft from one end and outlets are provided at the ends of the bearings (G and H) leading direct to separate drainage tanks in which the amount of oil seepage at each end of the bearing can be measured.

The oil is supplied to the various inlets under air pressure which can be varied from 25 to 100 lb. per sq. in. The oil line between the supply tank and the inlets is surrounded for part of its length by a steam coil which is used to regulate the temperature of the inlet oil. The test apparatus is water-jacketed to provide means for controlling the temperature of the oil in the bearing itself during the tests.

The first set of tests was made to determine the quantity of oil passing through the bearing under various conditions of shaft speed, inlet pressure, size of inlet openings, etc. These tests were again divided into several series, of which the first dealt with measurements of the quantity of oil that passes through the different sizes of inlet holes and out the center of the shaft at various speeds and inlet pressures.

In these tests it was found that the quantity of oil passing through the bearing decreases with speed and that the decrease is much more rapid in the range from 250 to 1000 r.p.m. than

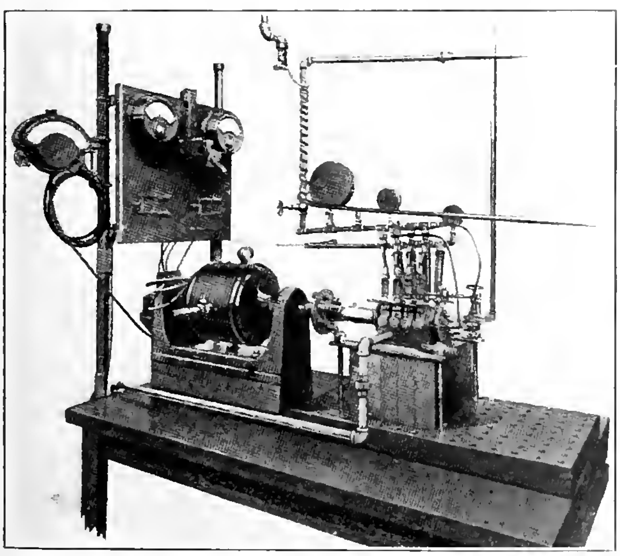

Fig. 5 General View of Dynamometer for Oil-Feed Tests

between 1000 and 2000 r.p.m., the curves having a more gradual slope at the higher speeds. As the latter represent normal engine speeds, an effort has been made to derive an empirical formula to cover oil flow in this range.

It was found that the quantity varies directly as the product of the pressure and the inlet-hole area. That is, when the area of the inlet hole is halved, the pressure must be doubled in order to obtain an equal quantity of oil at any fixed speed.

The formula derived from the results of these tests is as follows:

$$Q_b = \frac{1810\ (PA)}{S} \qquad [1]$$

where Q_b = quantity of oil in gallons per hour
P = inlet pressure in pounds per square inch
A = area of inlet hole in square inches
S = speed of shaft in revolutions per minute.

This formula may be slightly low with high pressures and large inlet holes, but it is substantially correct when the product of pressure and inlet-hole area does not exceed 5.

The next series of tests dealt with the quantity of oil flowing through the shaft from side inlet to side outlet; that is, through the inlet holes designated as A, B, C and D in Fig. 6, through the hollow shaft and out through the outlets A_1, B_1, C_1 and D_1 at various speeds and inlet pressures.

Centrifugal force set up in the oil inside the shaft complicates the problem of establishing a formula for the quantity values

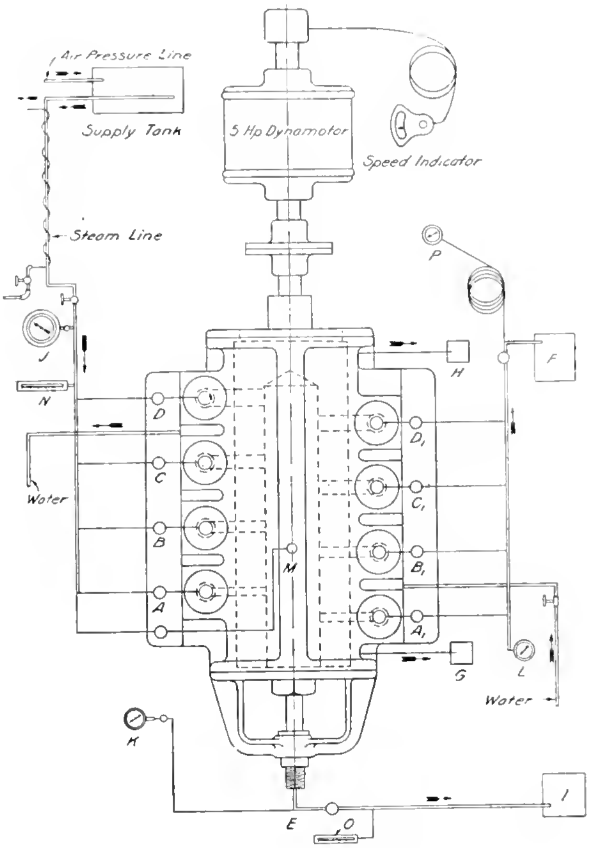

Fig. 6 Diagram of Installation for Oil-Feed Tests

obtained in these tests. The data of tests are presented in the original paper in the form of curves, in which, however, it is said that only the parts referring to speeds between 1000 and 2000 r.p.m. should be taken into consideration owing to the more abrupt character of the curves at lower speeds.

A formula to cover all cases has been derived from these tests, namely:

$$Q = \frac{1810\ (PA)}{S + \dfrac{6.9}{A_1}} \qquad [2]$$

where Q = quantity in gallons per hour
P = inlet pressure in pounds per square inch
A = area of the inlet hole
A_1 = area of the outlet hole
S = r.p.m. of shaft

Formula [2] is of the same form as the previous one. It may be used to cover all quantity calculations, because if it is considered that there is no outlet hole when the oil is not taken from the side of the shaft, A_1 becomes zero, and although not mathematically correct, it may be considered as canceled out, thus leaving the equation as it was first given. Values obtained with this formula do not in all cases correspond exactly with the results obtained in the tests, but they will be found to be sufficiently accurate to cover the entire quantity range in all ordinary design considerations.

An interesting series of tests were made to measure the amount

of seepage which took place around two special solid shafts used for this purpose. The results of these tests are summarized in the original article as follows:

1 The amount of seepage increases with the speed of shaft

2 The amount of clearance of shaft, within the usual range, has very little effect on the amount of seepage at normal speeds and pressures

3 The amount of seepage varies approximately inversely as the distance of the entering oil from the end of the shaft, being changed principally by the pressure

4 The amount of seepage varies directly with the inlet pressure.

An unusual result obtained in the two seepage tests was that in every case the seepage was greater with the smaller amount of clearance, which is quite contrary to expectations. This condition is difficult to account for, and it may be that it is peculiar only to the test apparatus used.

The effect of the distance through which the seepage must pass also was not according to expectations, and at lower speeds apparently was affected greatly by the amount of shaft clearance. For pressures of 40 lb. per sq. in. and over, the ratio of the seepage at the two ends G and H was practically the same for both shafts. The pressure seemed to play a part in the seepage ratio as between G and H, in that usually at pressures below 60 lb. per sq. in. the ratio was less than 2 to 1, but became larger as the pressure and speed increased, being as high as 3 to 1 at high speeds.

Tests were also made to determine the pressure inside of the shaft when the oil was led into any of the connections A, B, C and D. These tests have shown that the measured pressure in the hollow center of the shaft varies directly as the inlet pressure and also as the diameter of the inlet holes instead of as the area, as in the case of the quantity tests. Another conclusion drawn from these tests is, that with constant inlet pressure and a given size of inlet the drop in pressure due to speed increases more rapidly at high than at low pressures.

A formula has been derived from the data of these tests which provides mathematical means for determining the pressure in the hollow center of the shaft when the conditions are known. It is as follows:

$$p = \frac{5\ (PD)}{\sqrt{S}} \qquad [3]$$

where p = oil pressure inside shaft
P = inlet pressure
D = diameter of inlet hole
S = r.p.m. of shaft.

This equation will be found approximately correct from 500 to 1500 r.p.m. Above the latter speed it may be slightly in error, giving results as much as 4 per cent for each 100 r.p.m. above 1500.

Similar tests were made to determine the pressures at the side outlets of the bearing and it was found that the results corresponded in a general way with those obtained in the previous tests except that they were somewhat higher, so that the formula for pressure outside outlet is of the same form as [3], except that the coefficient is 6.8 instead of 5.

The final series of tests was conducted to determine the intermediate pressures for those in the center of the shaft with oil passing through from either of the side inlets to any one of the side outlets. When oil passed freely through the shaft the pressure in the hollow center portion varied considerably and did not follow any simple rule. In general, however, it was found that the internal pressure increased with the inlet pressure and also with increase of the size of the inlet hole, and decreased with increasing speed. Further, the drop in pressure due to speed is greater with the higher inlet pressures.

The original article is accompanied by a number of interesting curves. (*Bulletin of the Experimental Department, Airplane Engineering Division*, Bureau of Aircraft Production, War Department (Confidential) vol. 2, no. 3, December 1918, pp. 122-142, 18 figs., *e.t.* Abstracted by special courtesy of the Bureau of Aircraft Production, War Department).

MACHINE TOOLS

Automatic Arresting Motion for Power Presses

Automatic Arresting Motion for Power Presses. Illustrated description of a mechanism developed in England which it is claimed can be applied to that type of machine in which a flywheel revolves freely on its shaft until a positive connection is established between the two parts by rocking the spring-pressed rolling pin or bolt into engagement with the longitudinally recessed key or striking piece extending the entire length of the flywheel hub, this rolling pin or bolt being usually either kept in engagement so that the intermittent movement of the slide is continued or automatically disengaged after each complete revolution so that the slide may be stopped at its highest point after each single stroke. The inventors have provided an automatic mechanism whereby the slide might be brought to rest at the bottom of the down stroke, in addition to stopping at the highest part of its stroke. The holding at the bottom of the stroke is intended primarily to give the article being stamped a longer period in which to assume the desired form while still under pressure in the dies.

Referring to Fig. 7, A is the side frame of the press, and B the slide-operating shaft upon which the flywheel C revolves freely, until a positive connection is established between them through the spring-pressed trip lever D^1 rocking the rolling pin or bolt D of the shaft B into engagement with the longitudinally recessed key or striking piece E of the flywheel C, all of which are of ordinary construction.

In the invention under consideration there are fixed to the side frame of the press over the shaft B a bracket F having bearings G carrying a bar H formed with a tappet lever J, and being connected by means of a lever K to the upper end of a rod L of an eccentric M mounted on a countershaft N carried in bearings O of a bracket P, which is also attached to the side frame of the press. To the frame, too, but below the shaft B, is a fixed bracket Q, having bearings R carrying a bar S formed with a tappet lever T, and being connected by means of a lever U to the lower portion of the rod L. Rotary motion is imparted to the countershaft N from the flywheel C through the medium of chain gearing V, the chain wheel V^1 of which is loosely mounted on the countershaft N. The chain wheel V^1 is adapted to be locked to the countershaft N at will, through the medium of a slidable clutch W mounted on the countershaft.

On the countershaft N being driven by the chain gearing V the eccentric M has the effect, through the medium of the rod L and levers K U, of rocking the bars H S in their bearings G R, so that the two tappet levers J T are alternately rocked into the path of the spring-pressed trip lever D^1 of the rolling pin or bolt D, so as to cause the shaft B to be disengaged from the flywheel C twice during each revolution of the said shaft, the first disengagement being effected when the slide is at the highest point of its upstroke, and the second disengagement at the time the slide is at the bottom of its downstroke. The ratio of the chain gearing V and the action of the eccentric M may be proportioned as to give any desired amount of dwell to the slide to suit the work to be performed. For instance, with a 3 to 1 gear, such as is that which is fitted to the machine shown in Fig. 0, one revolution of the flywheel C would give a single reciprocation to the slide, while each of the other two revolutions would be rest periods for the slide at the top and bottom of its stroke respectively.

The countershaft N is fitted with a brake block X which is pressed upon by a spring, and which serves to arrest the movement of the shaft when it is thrown out of gear by the clutch W. The tappet-carrying bars H S are also fitted with springs H^1 S^1 for absorbing the shock set up when the trip lever D^1 strikes the tappet lever J T. (*The Engineer*, vol. 127, no. 3293, February 7, 1919, p. 135, 2 figs., *d.t*)

MARINE ENGINEERING (See Internal-Combustion Engineering)

MECHANICAL PROCESSES

New Process for Casting Formed Tools

DAVIDSON PROCESS OF CASTING FORMED TOOLS, J. E. Johnson, Jr., Mem.Am.Soc.M.E. The production of formed tools such as milling cutters, large drills, countersinks and other shapes from high-speed steel by methods hitherto known is an expensive operation. First, a blank of suitable size must be produced by forging an ingot or large bar. After forging, the rough blank is annealed and then sent to the toolroom for machining. This must be done with great care and accuracy and usually involves a multiplicity of operations, since, for example, the formation of each tooth in a milling cutter involves several cuts.

The notable features are three: First, the extraordinary freedom from blowholes; second, the fluidity of the metal; and third, the entire absence of coarse crystallization anywhere in the casting.

In regard to the first of these features, it may be stated that the foundry ran for several weeks before the completion of its baking oven, pouring the steel largely into green-sand molds, and yet made satisfactory tools, there being only a few steam holes near the surface. Since the drying oven was put into operation, blowholes of any description are practically unknown. In regard to the second, the metal, instead of having a comparatively ropy pour, is thin and fluid—more like hot cast iron than like steel. As a result the details of small cutters are cast practically perfect.

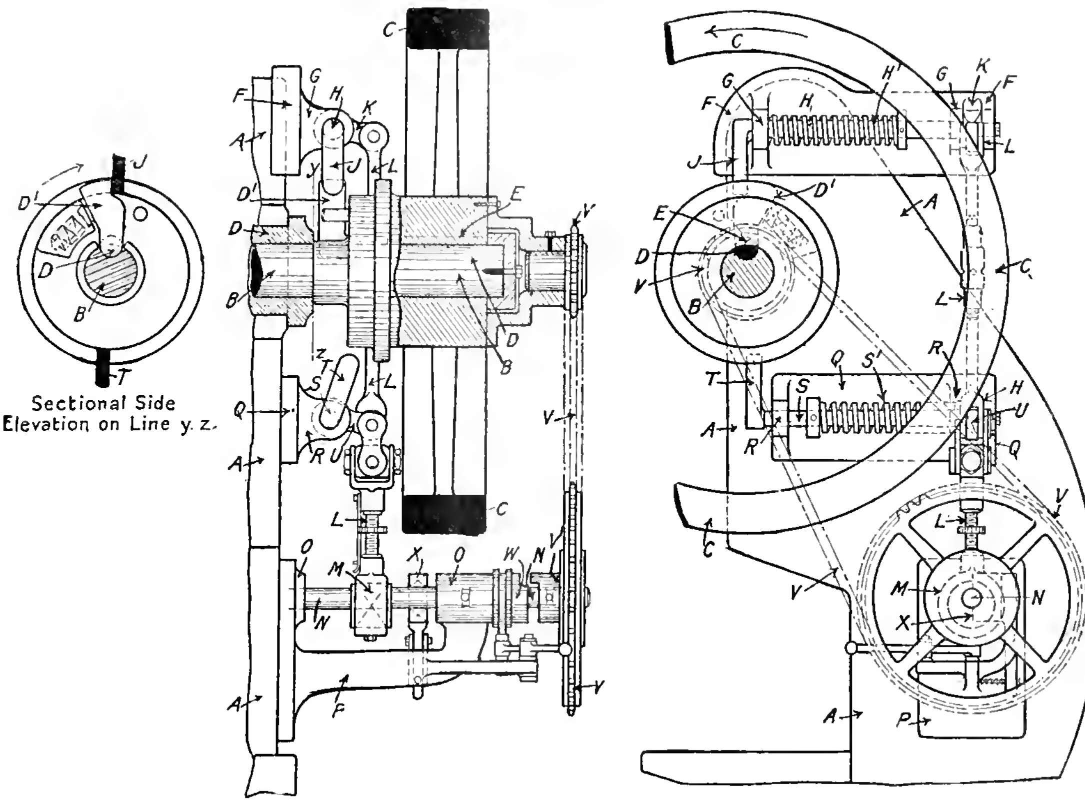

FIG. 7 "WHITE GLOVE" AUTOMATIC ARRESTING MOTION FOR POWER PRESSES

Various processes have been tried for casting tools to shape in the last two or three years and it is understood that one large manufacturer has such a process in more or less regular commercial use. There are three difficulties with this process from the point of view of ordinary steel-melting practice: (1) That of getting the steel killed so dead that it will be free of blowholes as cast; (2) that of producing a metal fluid enough to flow into the fine parts of the mold and give sharp, true castings. (If this cannot be done, only the rough cuts in machining the cutters are saved and the difficulty involved in cutting the scale may easily offset this gain); (3) that of producing a satisfactory structure to give great endurance and long life to the steel without the refining of the grain, which is often considered to come only from the forging operation.

A new direct casting process has been developed by A. C. Davidson with the assistance of Mr. Johnson, the author, and this is described in the paper and certain data on the history of the development of the process are presented.

From what is stated in the paper it appears that milling cutters are cast with a projecting lip on the cutting edge. This is finished entirely by grinding and with little more expense than the grinding of a machined tool. A perfect edge is obtained in this way with a minimum of labor and lost steel, while the possibility of local defects is avoided.

The material used for killing is a secret of which the author has no knowledge; he is, however, very enthusiastic over the results. The results described in this paper are not picked samples but represent the general run of the work done.

In regard to the third feature, it is well known that most steel, when cast, has a coarsely crystalline or fiery structure, but an examination of the fresh fractures of this steel shows that this is almost wholly absent; in fact, the structure of this steel, as cast, looks much more like that of forged steel than it does like a casting.

Various photomicrographs of a tool manufactured by the Davidson process are presented. From them it appears that the structure consists of a light matrix in which are embedded three other constituents. One is a dark, mottled material resembling troosto-sorbite in ordinary carbon steel and also resembling the dark constituent in a cast high-speed steel of ordinary composition. The second constituent is a light, hard one forming a herringbone design and is plainly a eutectic of some sort. The third constituent consists of a series of separate, small, rounded, hard, white spots similar to the excess carbide found in an ordinary high-speed steel both before and after hardening, provided the sum of the carbon, tungsten and chromium contents are high enough.

The author concludes with the following statement:

"Since the feathery constituent mentioned by Mr. Boylston, and shown in the photomicrographs of the Davidson tool, appears from Mr. Boylston's statement to be rather rare and is abundant in this steel, I am led to think that the surprising quality of these

tools may be due, in some degree, to the presence of this constituent. It seems well to point out here, however, that the metallography of the cutting tools is not sufficiently developed to enable us to say, even from a good photomicrograph, that a certain tool is definitely good or bad. The science will undoubtedly reach a state of development where this will be possible, but for the present the only safe gage of the quality of high-speed steel tools is a test under working conditions, the test to be continued to destruction if possible. Judging from the number of cases in which the cast tools have outstripped all others in such tests, a suggestion not unworthy of consideration is that the structure shown by the Davidson tools is that at which other toolmakers should aim." (*Bulletin of the American Institute of Mining Engineers*, no. 146, Feb. 1919, pp. 353-360, 6 figs., *d*A)

MEASURING INSTRUMENTS

Resilience Factor in Instrument Calibration

The Concept of Resilience with Respect to Indicating Instruments, Frederick J. Schlink, Mem.Am.Soc.M.E. In an earlier paper entitled Variance of Measuring Instruments and Its Relation to Accuracy and Sensitivity (Bureau of Standards Scientific Paper No. 328, 1918), the writer discussed the so-

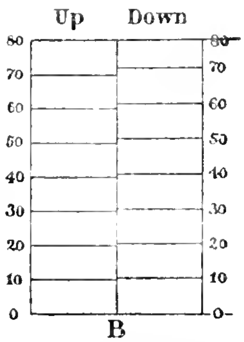

Fig. 8 Calibration of Ordinary Steam-Engine Indicator

(Reproduced from a textbook on the indicator; shows the equivalent, when pencil displacement is plotted against pressure, of a closed hysteresis loop)

called hysteretic types of errors. The hysteresis loop obtained upon the performance of a proper cyclic calibration gives a representation of the behavior of an instrument as regards the consistency or reproducibility of its calibration. Furthermore, a simple quotient of the areas marked out by the cyclic calibration curve defines a factor which may be called the resiliency of an indicating or controlling instrument.

There are actual energy losses which occasion the hysteresis in the calibration and the nature of which is discussed, and it appears that the variability of a non-integrating instrument can always be expressed in the form of a lost-work diagram, although in some cases the transformation of the coördinates must be resorted to to permit direct planimetric evaluation of the losses.

In order to give such a hysteresis loop definiteness and value for the purpose in hand, the instruments must be operated a number of times over the cycle under investigation in order to get it into the cyclic state, just as is done in determining the hysteresis characteristics of magnetic specimens and in exact determinations of the stress-strain relations of structural materials. Moreover, between the points of reversal, the change of the independent variable, that is, the quantity which the instrument is intended to measure, must take place slowly and aperiodically and without jarring or vibration, so that the pointer at no time overshoots its reading, since all revertive or vibratory movement of the mechanism tends to displace the corresponding part of the hysteresis loop toward the normal or ideal calibration line to an extent dependent upon the magnitude and number of the precedent excursions. Setting up the cyclic state as defined above, has the effect of obliterating, as it were, the previous operational history of the instrument and of making the hysteresis loop a closed figure of definite area. It is recalled that the hysteresis effect observed in common indicating instruments is in large measure due to journal friction, and that the slack-bearing condition or backlash, so-called, is responsible in a quite definite way for the phenomena noted. It appears that the cyclic state can be readily set up in all indicating instruments except those in which transient phenomena are of importance even at relatively slow rates of change of indication, and second, those in which an uncompensated backlash exists. Even in the latter case, the difficulty in setting up the cyclic state applies only to a fraction of the range of indication or operation, while in the former it has been shown that if the rate of change of the independent variable be constant, cyclic performance is ultimately possible.

It has been already shown experimentally that the normal loop corresponding to cyclic operation of a typical instrument without viscous drift or elastic after-effect, over its full capacity range of operation, is a maximum of all loops obtainable for any two turning points lying between the chosen extreme turning points, and, moreover, completely encloses and circumscribes all such minor loops, a result which involves conclusions of direct value in permitting the utilization of indicating instruments of very ordinary quality for work of relatively exact character, to which they have not hitherto been considered adaptable.

Both the shape and the area of the hysteresis loop come into consideration, in defining distribution of the energy loss in the

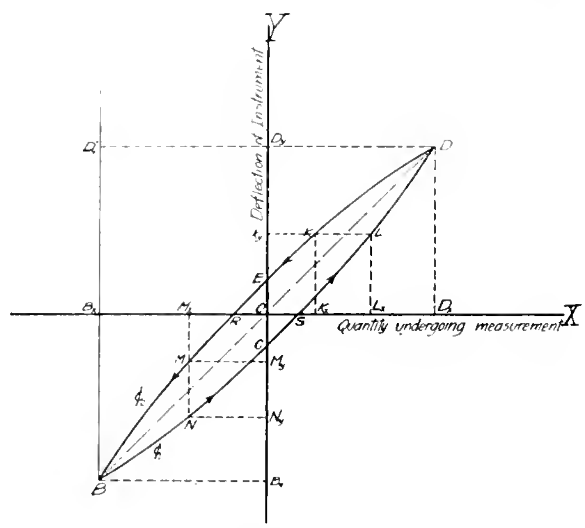

Fig. 9 General Form of Hysteresis Loop of an Instrument Reading in Both Directions From a Central Zero

$K_x L_x$ = range of values of the quantity measured for a given deflection K_y

${}_yN$ = range of deflection or indication for the value M_x of the quantity undergoing measurement

Area $BCDE$ = energy dissipated in the instrument during the cycle

Area $BEDD'_y$ $= \int_{By}^{By} [\phi_1(y) - \phi_2(y)]dy$

Area $BCDD'_y$ = efficiency of resilience or *resiliency* of the instrument over the cycle BDB.

instrument over the operating range, as well as the amount of such loss.

The diminution of frictional lag, occasioned by properly applied vibration treatment, is very striking, and it would appear that in cases where the determinate nature of the hysteresis observed under the stated conditions does not suffice to make the instrument usable for a given purpose, in-built mechanical or electrical vibrators analogous to that used in the Cuttriss modification of the Kelvin siphon recorder would be distinctly serviceable. It seems reasonable to suppose that vibration will also reduce that portion of the hysteresis which arises in imperfect elasticity or other molecular causes, including even irreversible time effects, since it has been shown to act with that

tendency in the case of transient and intransient magnetic and electric phenomena.

Experimental data are not available to permit of satisfactory analysis of the energy loss associated with the movement of a liquid meniscus in a tube and in similar circumstances, which is the problem offered by manometers, spirit levels, hydrometers, etc. It is definitely known, however, that a measurable intransient instrumental lag exists in such instruments, and the author ventures the suggestion that the effect may be the one well known in inverse form in the capillary electrometer or possibly the thermodynamic transfer involved in all changes in the configuration of a free liquid surface, as treated in the work of Kelvin. It is undoubtedly true that the irreversibility of a liquid-column instrument must often be taken into practical consideration, and the common assumption that such effects are absent or negligible is by no means a safe one. The case of a dirty liquid surface, such as is sometimes seen in a barometer, is of course simple, and the action easily accounted for on the basis of a granular type of friction. The evidence, however, appears to indicate that this is by no means the sole or even the most potent cause of the difficulties with respect to variability met with in liquid-column instruments.

Quantitative comparison of instrument performance by the use of their resiliences requires equivalence of the range of reading or operation for the instruments compared or determination of the function connecting energy loss with the range of observation. This latter is now known for but a limited class of instrument elements. (Elastic Hysteresis in Steel, F. E. Rowett, Roy. Soc. Proc., vol. 89A, p. 528, 1913.)

Distinction is drawn between the utilization in the performance rating of instruments, of the ordinary methods based upon calibration errors and of the proposed method based upon efficiency in energy restoration; and it is held that the latter affords a generally applicable means for distinguishing between the performances of diverse types, while the former method judges rather between individuals. An instrument having high resilience is capable of being given precise adjustment and of utilizing it to advantage in affording a minimum average departure of readings from the mean. When it is recalled that the mean error at any point of the instrumental scale can be readily reduced as nearly to zero as we may desire, by proper adjustment of the instrument or by remarking the graduations, it will be seen that the calibration error affords but limited information as to the possibilities of the instrument. On the other hand, the variance errors as completely exhibited in the hysteresis loop are in large measure inherent and cannot be eliminated by any such adjustment, so representing within certain limitations rather the performance of the class to which a given operating principle or mechanism pertains. It is shown that the true criterion for the utility of a given operating element, when ultimate accuracy is the dominant consideration, is the measure of the contribution of that element to the hysteresis loss of the instrument whether that contribution be the effect of frictional resistances or of imperfect elacticity. (Bureau of Standards, Advance publication, *tA*)

METAL-WORKING TOOLS

British Inserted-Tooth and Thread Milling Cutters

British Milling Cutters. Abstract of two articles in recent issues of *The Engineer* (London), the first describing the so-called Francis inserted-tooth milling cutter, as to which very little information was available until quite recently.

This cutter was developed at one of the British National Shell Factories in order to permit the production of howitzers on tools previously used for shell manufacture, the problem being to perform by means of a lathe operations which would have been performed in the usual course of things by means of a planing machine. In this instance it was desired to remove surplus metal in an operation on a howitzer tube by means of two lathes converted into a horizontal milling machine. To do this it was necessary to take the cut not along the length of the barrel but around it, and for this the cutter would have to be something over 2 ft. in length. The Francis cutter was developed to take care of such operations as this. There are two particular points of novelty about it, viz., the manner in which the teeth are arranged on the body and the manner in which they are attached to it. The first point is illustrated diagrammatically in Fig. 10. In the ordinary type of inserted-tooth milling cutter the body is grooved with a number of spirals in the direction indicated at *C*; that is, approximately parallel with the axis of the cutter. Each slot is filled either with a single blade or with a number of individual cutters *B* separated by distance pieces *E*. In the latter case the teeth in one slot are arranged to slightly overlap longitudinally the teeth in the succeeding slot, so that taken as a whole the teeth

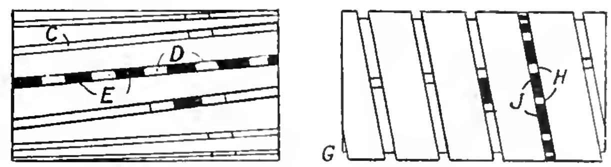

Fig. 10 Methods of Inserting Teeth in Milling Cutters of the Ordinary (left) and Francis (right) Types

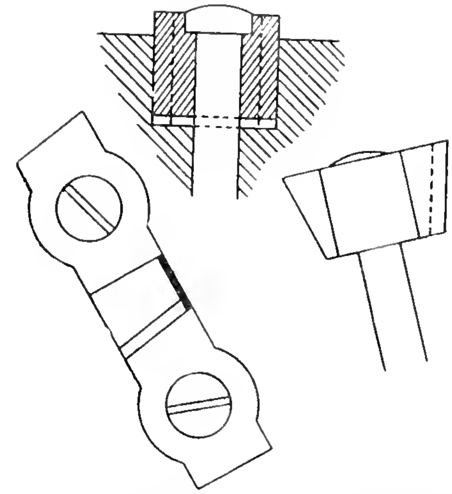

Fig. 11 The Most Recent Type of Francis Cutter

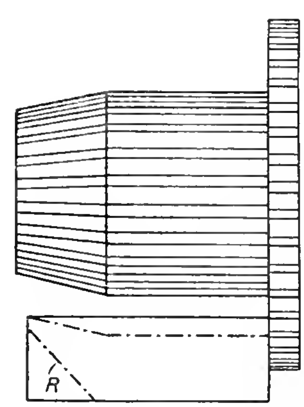

Fig. 12 Method of Forming the Teeth in the Francis Milling Cutter

follow one another round the body in a spiral, approximately at right angles to the axis of the cutters. This is shown in the left-hand view. In the Francis cutter (right-hand view) the grooving forms one continuous spiral around the body of the cutter substantially parallel with that on which the teeth lie in the ordinary cutter. The groove is filled with teeth *H* and distance pieces *J*, the teeth being disposed so as to form rows substantially parallel with the grooves in the ordinary cutter. Therefore the teeth in both cutters occupy the same relative position, with the difference, however, that in the ordinary cutter they are forced by the

pressure of the cut against the edges of the grooves, that is, against the metal of the body, while in the Francis cutter the teeth are pressed against the distance pieces. This difference is of considerable practical importance. In the ordinary cutter the tendency is for the pressure of the cut ultimately to widen the cross-section of the grooves so that the teeth become loose, and the cutter body is rendered useless until the grooves have been reshaped. In the Francis cutter the distance pieces are case-hardened. The pressure of the cut does not tend to deform the cross-section of the groove, and should slackness develop as a result of the cutting pressure it can readily be taken up by simply tightening the wedges or distance pieces. In actual practice, though,

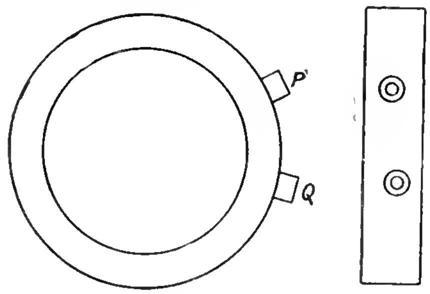

Fig. 13 Special Jig Used for Drilling Holes in Francis Cutter

it is found that the pressure of the cut renders the teeth not slacker but tighter, so much so that when it is desired to recharge the cutter it is invariably found that the teeth and wedges have settled down so firmly that after the securing screws have been loosened the wedges have to be jarred from their seats before the teeth can be removed.

The most recent form of the cutter is shown in Fig. 11, this form being convenient both from the point of view of operation and from that of toolroom production. The wedges which formerly had rectangular ears are now formed with circular swellings on their faces and are plane surfaced both on the top and bottom. It is found possible to produce them in this form with sufficient accuracy by drop-forging the parts requiring only to be drilled and touched up by grinding before being case-hardened. Furthermore, the substitution of the round swellings for the square ears permits the undercutting of the groove to be dispensed with and the concave recesses can very readily be formed by drilling after the groove has been cut. A special jig shown in Fig. 13 has been developed for this when the holes are being bored. It is in the form of a ring which is clamped round the cutter body by means of set screws and carries two drill guides P and Q, the pitch of which is accurately fixed as the value required to give the desired alignment of the teeth. With the jig fixed in position the first hole is drilled through the guide P, the jig is then rotated until an accurately fitting plug can be passed down the guide Q into the hole already drilled. The second hole is then drilled through the guide P, the plug is removed and the whole operation repeated until the whole surface of the cutter body has been covered.

The method of forming the teeth is illustrated in Fig. 12. The block of high-speed steel, cut roughly to length, is placed in a small vise which holds it at the required angle, and a milling cutter of special form is fed across it to face the base and form the front flank. It will be noticed that the milling cutter is coned so that the tooth is formed with a rake at the cutting end. The angle of this rake is sufficient to bring the front flank of the tooth five or six degrees beyond being radial when the tooth is assembled on the body. Thus the teeth are given a positive front rake. It is usual in ordinary milling cutters, at least such as are used for finishing cuts, to make the front flanks of the teeth radial. A positive front rake is, however, advocated by some as a means of increasing the life of a roughing cutter, and this has been followed in this case. The corner R, Fig. 12, has still to be removed. At present this operation is performed by an additional milling process, but as the surfaces at R, when the teeth are completely assembled on the body, lie in a series of spirals—see Fig. 10—it is proposed to assemble the cutters R by grinding. The relief and sharpening—and subsequent resharpening after use—of the actual cutting edges of the teeth are effected by means of the arrangement illustrated in Fig. 14. In this arrangement the cutter is fed longitudinally over toward the left past a grinding wheel. The pressure of the wheel on the edges of the teeth holds each tooth, as it passes the wheel, down on to a pointed guiding plate up which the under surface of the tooth travels by reason of the longitudinal feed. In this way the cutter is automatically rotated by just the right amount as it moves along. The axis of the cutter is of course set a little below the axis of the wheel, so as to give the requisite relief to the cutting edge.

The article describes in considerable detail many of the applications of the Francis cutter; for example, its use for the machining of 6-in. howitzer breech rings and the machining of staybolts for naval 10-in. bomb throwers on an adapted lathe. (*The Engineer*, vol. 127, no. 3288, Jan. 3, 1919, pp. 6-8, 18 figs., *d*).

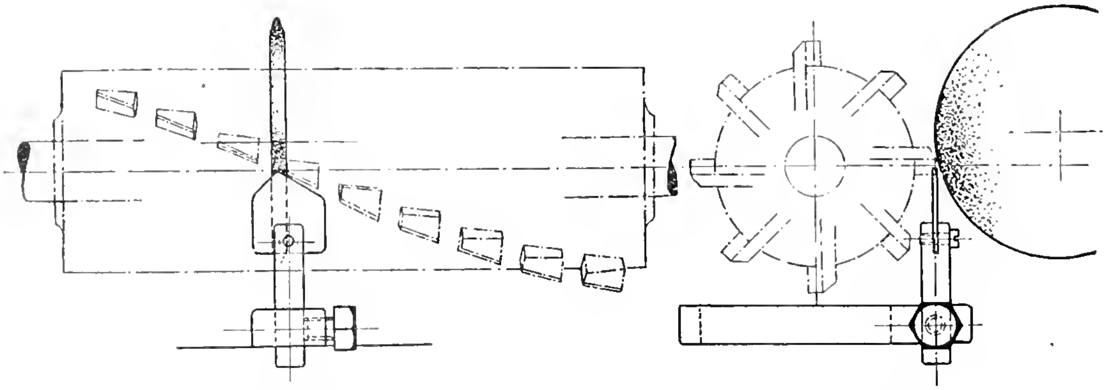

Fig. 14 Relieving and Sharpening Teeth of Francis Milling Cutter

Another British type, in this instance for thread milling, is represented by the "Cycloid" cutter, Fig. 15. It has been found in external thread milling that the ordinary thread-milling hob has a tendency to produce "waves" and "flats" on the work. By "flats" is meant any portion around the circumference of the work at which the diameter of the work is less than elsewhere and the tendency to produce them may be ascribed to the fact that the thread-milling hob has a concave cutting action in relation to the work; in other words, that the cutter tends to get into and below the arc line of the circle it is operating upon.

The Cycloid cutter is claimed to be capable of overcoming this. The cutter head is designed as a hollow cylinder and is attachable to an ordinary chuck plate. The cutter end of the head is milled at intervals to receive a series of independent thread-milling cutters, which are clamped in position in the cutter head by means of slotted studs, fitted with nuts. The independent cutters are backed off, or relieved, and are adjusted internally by means of diametric gages, which enable each cutter to be set truly to any

given diameter within the scope of a given size of head. The cutter, when assembled, has the general appearance of an inserted-tooth die head, but there are the following differences: The inserted teeth are backed off; they are of less width; the thread cutting angles have no thread pitch; the cutter circle exceeds the diameter of the work.

The cutter rotates on the live spindle of the machine. The work, on a work-holding spindle fitted with a leading screw, is brought within the plane of the cutters to the desired extent, and is then moved transversely on the slide toward the cutters until the desired depth of cut is obtained. The work is then rotated until the thread-milling operation is completed.

It will be seen that the cutting teeth of this cutter move in a circle around the work, and therefore describe an arc of a circle which is more or less parallel with the arc of the circle it is desired to produce on the work. Each cutter makes a convex sweeping cut on the work, and at least three cutting teeth, it is stated, are usually actually cutting on and around the work at the same time. A more perfect circle can thus, the designers claim, be produced by their cutter than by one made on the old method. It is further claimed that in the event of an inserted cutter being broken it can be taken out and another substituted at little cost. The independent cutters do not distort in hardening, and can be relied upon to run true, so that "waves" are avoided. They can be quickly removed from the cutter head, and ground on any ordinary type of grinding wheel which is in good condition, and can be replaced by any mechanic of average ability. The cutter head will take a fair range of work of varying diameters, and can be made on the hollow-spindle principle to run in bearings for screwing shafts, etc. (*The Engineer*, vol. 127, no. 3294, Feb. 14, 1919, p. 159, 1 fig.)

POWER-PLANT ENGINEERING

High-Pressure and High-Temperature Steam in Large Power Stations

The Use of High-Pressure and High-Temperature Steam in Large Power Stations. The writer discusses the subject from the point of view of expediency, mainly on the basis of British practice. He says that a good case can be made out for a jump to 600 lb. pressure with the total temperature of 700 to 800 deg. fahr., which will, however, involve a considerable amount of development and experimental work being borne by the enterprise first to adopt such a pressure. On the other hand, it appears that practically all designs of existing apparatus can be so modified as to admit of pressure from 350 to 400 lb. per sq. in. He believes therefore that the pressure of 350 lb. can safely be adopted.

When considering any results of tests on high-pressure or high-temperature steam-generating plant, it is essential that the tests on the boiler side and the tests on the turbine side be studied separately; furthermore, it must be remembered that any results obtained on an extra-high-pressure boiler can be obtained and considering the boiler apart from the economizer, surpassed on a similar and similarly equipped low-pressure boiler. The use of the temperature-entropy diagram is recommended to determine the gain due to increasing the working pressure and temperature ranges of steam.

The writer makes up several schedules showing the comparisons of coal, steam and heat consumptions in various plants operating under various conditions.

Table 1 is a schedule of particular interest in this connection. It was made for a 20,000-kw. machine running at 200 lb. and 350 lb. pressure by gage at various superheats; also at 500 lb. pressure absolute and 268 deg. superheat, at which pressure and superheat the total temperature will be 736.5 deg. fahr., which is about the maximum temperature at present recommended for materials now used in turbine construction. For the purpose of these calculations a turbine ratio efficiency of 80 per cent is assumed at both 200 and 350 lb. pressure, with the steam superheated 150 deg. and a constant vacuum of 28.5 in.

This schedule shows that the cost for coal when generating 175.2 million kw-hr. with a load factor of 100 per cent will be £64,400 at the higher pressure and superheat 250 fahr., and £69,200 at the lower pressure with corresponding superheat. Unfortunately the load factor of 100 per cent is impossible and the conditions under which power stations are operated must be considered before even an approximate estimate of working costs can be arrived at.

In this instance the writer proposes to assume the same standing loss of coal due to no-load consumption for the station design for 200 lb. as in an actual British power station of approximately the same dimensions, which is 1583 lb. per hr. For a 20,000-kw. set the no-load consumption will be approximately 22,000 lb.

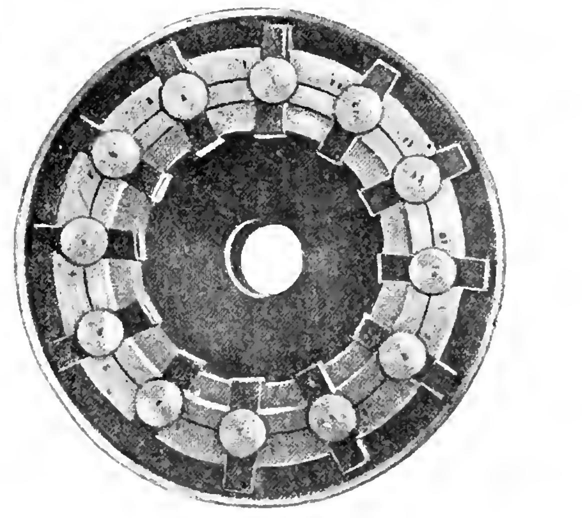

Fig. 15 Cycloid Thread-Milling Cutter

of steam, or 3666 lb. of coal per hr., and these figures plotted in conjunction with the steam consumption shown in Table 1 give the total steam consumption at any load as 22,000 lb. plus 9.54 lb. of steam per kw-hr. for the plant operating at 200 lb. pressure; 22,000 plus 8.6 lb. of steam per kw-hr. and 3729 lb. plus 1.45 lb. of coal per kw-hr. for the plant operating at 350 lb. pressure and 250 deg. superheat.

With regard to the practical difficulties, it is only to be expected that, before pressures of 500 or 600 lb. per sq. in. are adopted, a radical departure will have to be made in present boiler construction. All square boxes and headers will be eliminated, the drums and tubes will be smaller in diameter, and the design of the boiler made more elastic. The type of boiler will no doubt assume the appearance of a flash boiler, with practically no steam or water reserve, and fired by gas on the surface-combustion principle.

For the more moderate pressures, up to 350 lb. per sq. in., the existing type of boiler can be modified and successfully used. At the Carville power station Babcock & Wilcox marine-type boilers are being used at 275 lb. per sq. in. gage pressure, and at the British Thomson-Houston Company's works at Rugby a Babcock & Wilcox boiler is installed and successfully working at 350 lb. per sq. in. Further, Messrs. Babcock & Wilcox state that they have at present two boilers on order for a working pressure of 475 lb. per sq. in. with steam superheated to a final temperature of 700 deg. fahr., and that they are quite prepared

to supply boilers in their ordinary business for such pressure and superheat.

With higher steam pressure the temperature of saturation is raised and, due to this, greater care must be exercised in the quality of the water used for the boiler feed. A feedwater that is perfectly satisfactory at 380 deg. fahr. in a modern tubular boiler might be quite unsuitable for use in a flash boiler. The quantity of air, CO_2, and oxygen will have to be kept down to a minimum, and also the non-soluble salts which are generally in the water discharged from an ordinary lime-soda water softener. A natural development, and one which is already taking place, is to heat the feedwater under atmospheric pressure by means of live or exhaust steam in order to drive off the entrapped and dissolved gases as much as possible. According to a table extracted from Lunge's Technical Chemist's Handbook, it is necessary to raise the temperature of the water to 100 deg. cent. before the quantity of air in the water is appreciably reduced.

The source of water for use in high-pressure plants will have to be carefully traced, and the treatment of the water should be such that a minimum of unsoluble salts remains in it after treatment. The purer the water the greater affinity it has for air, CO_2, and oxygen, and every care should be taken that it is not exposed to the air between the condenser and the boiler. In order to avoid such exposure to the air it is suggested that the feed pump should be an extension of the condensate pump and the condensed water pumped direct into the feed line.

The natural development of the turbine for higher pressures appears to be in a line with the Parsons two-cylinder machine, with a flexible claw-type coupling between the cylinders and a thrust bearing for each cylinder. For very large sets, above 50,000 kw., the cross-compound turbo-generator will no doubt be used, with each side connected to a separate generator. Each set can then be run at its most suitable speed, with resulting high efficiency. This arrangement will no doubt lead to reheating the steam after it leaves the high-pressure turbine and before entering the low-pressure machine. Dr. Ferranti has already done valuable work on this subject, the results of which have unfortunately not been published.

The design of the condensing plant is not likely to be modified because of the use of high-pressure or high-temperature steam, but the fact must not be lost sight of that with steam initially at the same temperature but at different pressures the plant using the high-pressure steam will reject less heat units to the condenser per pound of steam used in the turbine.

The steam pipes to be used in a station where both high pressures and high temperatures are employed will have to be very carefully designed. (*The Journal of The Institution of Electrical Engineers*, vol. 57, no. 278, Jan. 1919, pp. 73-82, *pt.1*).

TABLE 1 TESTS OF A 20,000-KW. TURBINE AT HIGH STEAM PRESSURES AND SUPERHEATS

Absolute Pressure at Turbine Exhaust, 1.5 in. Mercury (91.7 deg. fahr.). Condensate Temperature, 85 deg. fahr.

Steam Pressure at Turbine	215 lb. per sq. in. (abs.)					365 lb. per sq. in. (abs.)						500 lb. per sq.in.(abs)
Superheat of Steam at Turbine, Deg. Fahr.	100	150	200	250	300	50	100	150	200	250	300	268

Improved Method of Firing Oil Under Steam Boilers (*Zeitschrift für Dampfkessel und Maschinenbetrieb*, December 13, 1918). Oil blown into a furnace through a nozzle usually spreads conically, and there is difficulty in intimately mixing the spray with air so as to obtain perfect combustion.

Excess of air is usually admitted, even to the extent of 320 cu. ft. per lb. of oil, instead of the 170 cu. ft. theoretically required.

Good results have been obtained by permitting air to enter through a nozzle discharging to the interior of the conically shaped oil spray. The air should be heated by passing it through tubes embedded in the brickwork of the furnace, and meet the oil close to the orifice of the nozzle. The outer portion of the oil spray is supplied with air through the fire door in the ordinary way. It is possible in this manner to obtain intimate mixture before combustion takes place, and a high temperature of the internal air supply still further increases the efficiency.

It is advisable to have separate fans for the internal and external air supply, although they may be driven from the same motor in order that the air discharge may remain proportionate. The pressure of the latter must, however, be sufficient to overcome

resistance in the preheating pipes. (*Technical Supplement to the Review of the Foreign Press*, vol. 3, no. 4, Feb. 18, 1919, p. 113, no. 4216, *p*)

REFRIGERATION

Vapor Refrigeration Processes and Their Entropy Diagrams

Vapor Refrigeration Processes, Prof. P. Ostertag. A good way to secure a simple and clear comprehension of the cycle in the vapor-compression refrigerating machine is by using the entropy diagram. Heat energy dQ at temperature T may be considered as being a product TdS and may be represented as a strip on a plane surface with temperatures T as ordinates and entropy increments dS as abscissæ.

As long as the carrier of cold is in a liquid state the points representing the state of the matter are all located on the lower limit curve (specific volume of vapor $x = 0$) and the saturated state of the vapor is designated by the upper limit curve ($x = 1$). The curves to the left of the lower limit curve indicate the region of the elastic fluid and those to the right of the upper limit curve the region of the superheated steam, while the points between the two curves indicate the wet vapor. The Carnot cycle may be considered as an ideal process. The fluid carrier of cold (point A in Fig. 16) is superheated to the high pressure p_1 and to the correspondingly high temperature t_1. The high temperature t_2 necessary to produce cold is secured by adiabatic expansion (AB) in cylinder EZ, Fig. 17, whereupon a part of the liquid is gasified. The rest of the liquid in the evaporator V takes up an amount of heat Q_2 from the surrounding medium and thereby produces a cooling effect represented in Fig. 16 by the rectangle BCO_2O_1. Now the cooling material must be compressed to its initial pressure p_1, which is carried out adiabatically in cylinder KZ (CD, Fig. 16). If the end point D in Fig. 16 is still in the region of saturation (wet process), then as the last variation of state

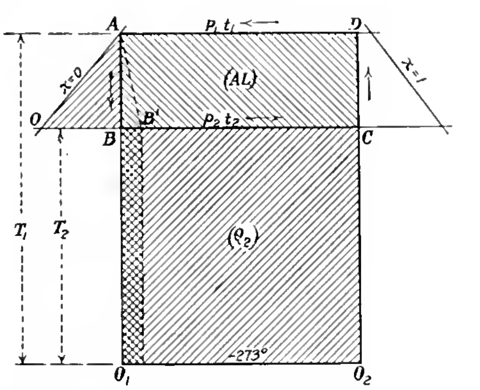

Fig. 16 Entropy Diagram, Carnot Cycle and Wet Process

DA, the heat Q_1 (rectangle DAO_1O_2) has to be abstracted, which is done in the condenser K.

The closed process gives a cold output K_2 and requires an expenditure of work K, of which the heat value AL ($A = 1/428$) is shown as the rectangle $ABCD$. From Fig. 16 it follows that

$$\frac{Q_1}{T_1} = \frac{Q_2}{T_2},\quad Q_1 = Q_2 + AL$$

The cold output per hp. is

$$q_s = \frac{Q_2 \times 3600 \times 75}{L} = 632\frac{T_2}{T_1 - T_2}$$

Hence the output of a plant is the greater the less the temperature difference between the cooling water and the brine.

The first deviation from the described process consists in replacing the expansion cylinder by a simple throttling valve (R in Fig. 17). In the diagram the line AB is replaced by the throttling curve AB'; the output of cold decreases by the rectangle comprised under BB' and the consumption of work increases by OAB.

The second change consists in the introduction of the *dry process*. There the compressor sucks in only vapor which is provided by the introduction of a liquid separator A_1 (Fig. 18) in front of the compressor. This carries the heat absorption in the evaporator up to the upper curve (point C in Fig. 19).

The compression at once brings the vapor sucked in into the state of superheat represented by the adiabatic line CD. Among the advantages of this process it was found that the cylinder contains no liquid which would condense on the walls and hinder the flow of heat from the walls to the vapor; furthermore, the

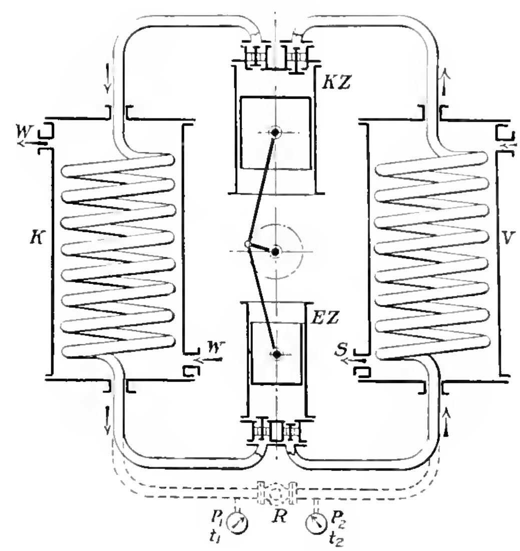

Fig. 17 Elementary Vapor Refrigeration Type Machine

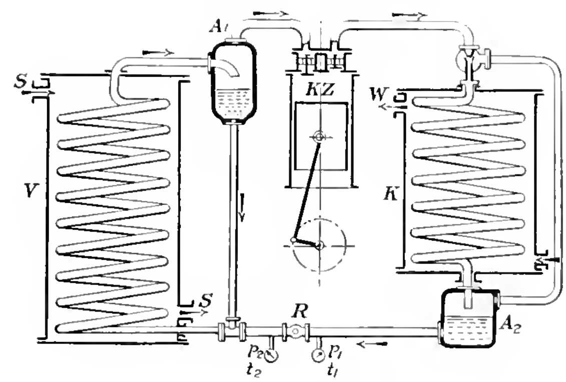

Fig. 18 Diagrammatic Representation of Dry-Process Vapor Refrigeration Type Machine

same condensed liquid decreases the efficiency of operation through evaporation from the clearance during expansion, which makes all presence of moisture in the compressor undesirable.

On the other hand, flooding is necessary to enable the flow of heat to occur freely. This is achieved by placing the liquid separator A_1 high and by leading back to the evaporator (Fig. 18) the liquid which has separated.

The compressor KZ forces the hot gas from above into the condenser K. If desired it is possible to produce a nozzle action at the entrance into the coil in order to suck away any gases that may remain in the collector A_2 and drive them once more into the condenser.

If the condenser has been so designed as to have a surface of liberal dimensions and the cooling water W is circulated in countercurrent at a lively rate, it is possible to cool the condensate below the temperature of saturation (from t_1 to t_u). In the diagram Fig. 19 the throttling curve AB shifts to A_uB_u and the gain in undercooling is represented by the rectangle of width BB_u. This action becomes particularly noticeable when carbon dioxide is used as the carrier of cold, since this material has a

very large heat of liquid. Frequently in plants of this type a special liquid cooler is placed behind the condenser as was done for example in the installation exhibited by Escher Wyss & Co. at the National Exposition in Berne in 1914.

For example, let it be assumed that in the evaporator there is a

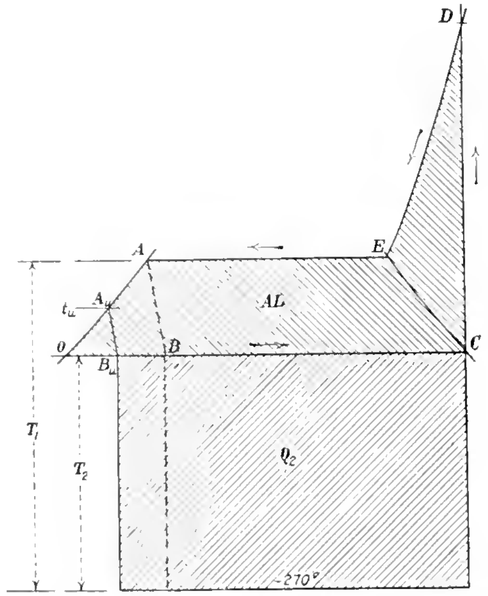

FIG. 19 ENTROPY DIAGRAM, TO ACCOMPANY FIG. 18

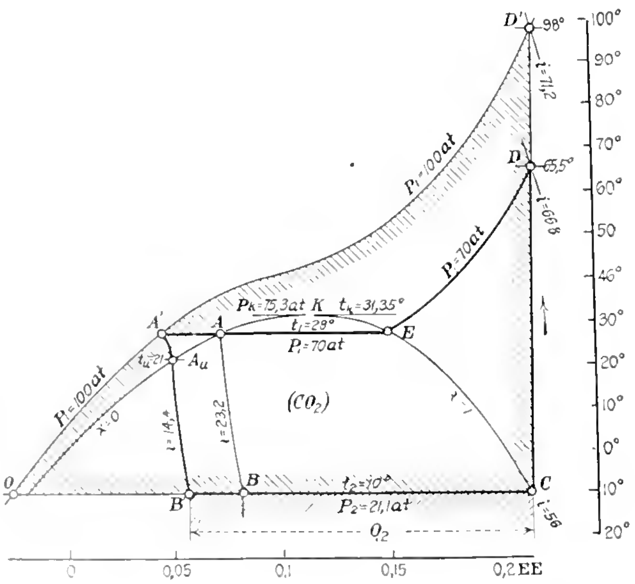

FIG. 20 ENTROPY DIAGRAM FOR CARBON DIOXIDE REFRIGERATING MACHINE

temperature of −10 deg. cent. and in the condenser one of 28 deg. cent. The compressor then has to compress the vapor from 27.1 atmos. abs. to 70 atmos. abs. (CD in Fig. 20). The work necessary for this purpose may be represented as the difference of heat content between D and C, or $AL = 66.8 - 56 = 10.8$ cal.

The condenser has to get rid of a considerable amount of heat in order to attain the state of saturation (area under EE) and still more heat (rectangle under EA) in order to liquefy the vapor. If no undercooling can take place, the material carries its heat of liquid $i = 23.2$ calories through the throttling valve into the evaporator (AB) where the heat output is $Q_2 = 56 - 23.2 = 32.8$ cal.

This gives per hp. $q_2 = 632 \times \dfrac{32.8}{10.8} = 1920$ cal.

The Carnot cycle would have given $q_0 = 632 \times \dfrac{263}{38} = 4370$ cal.

Hence, the efficiency as referred to the Carnot cycle is 44 per cent.

The results will be more favorable if we assume that the cooling water is capable of undercooling the liquid carbon dioxide to 21 deg. (AA_u). Then only 14.4 calories will be carried over into the evaporator and

$$Q_2 = 56 - 14.4 = 41.6 \text{ cal.}; \; q_2 = 632 \times \frac{41.6}{10.8} = 2440 \text{ cal.}$$

The efficiency will now be 56 per cent or 12 per cent higher than before.

In order that the same output of cold may be possible without there being an opportunity for undercooling the gas must be compressed to 100 atmos. (CD') and the consumption of work must be $AL = 15.2$ cal. The cooling occurs then above the

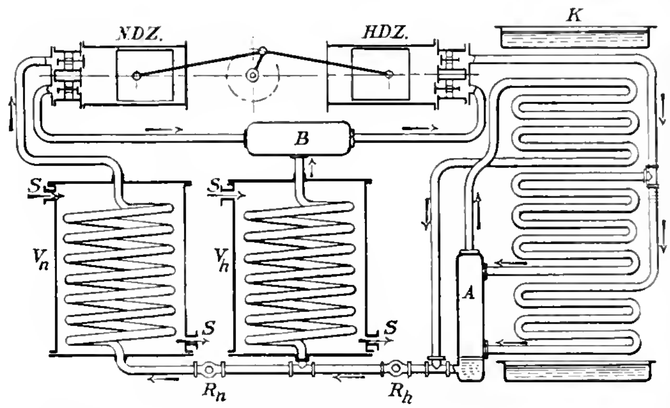

FIG. 21 REFRIGERATION MACHINE WITH INTERMEDIATE EVAPORATOR AND TWO-STAGE COMPRESSION

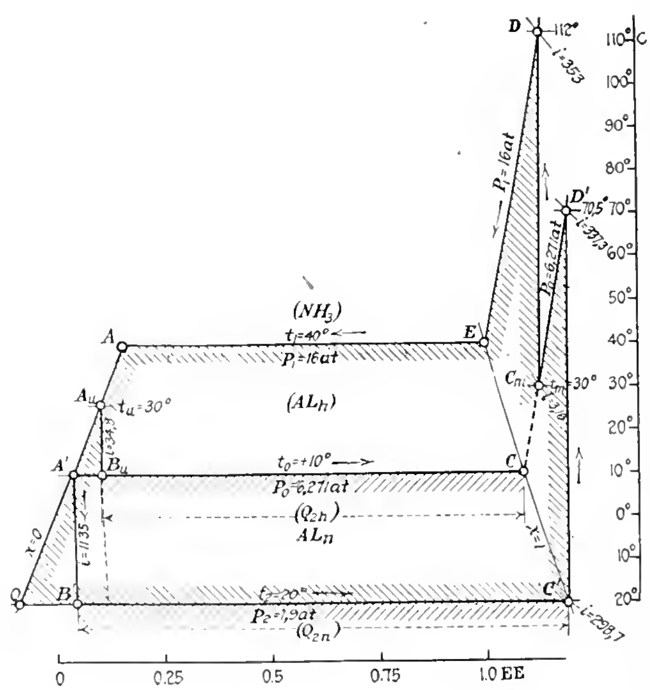

FIG. 22 ENTROPY DIAGRAM, TO ACCOMPANY FIG. 21

critical point K ($D'A'$) and the transition into the elastic or liquid state occurs without a sharply defined vapor formation.

Another process has been proposed by R. Plank. The gas is compressed only to 70 atmos. After the cooling the liquid undergoes an increase of pressure from 70 to 100 atmos. in another pump (AA') so that the same cooling effect is secured. The work of the pump in Fig. 20 is shown as a rectangle under AA', but on the other hand, the work of the compressor is somewhat less as indicated by DD'.

In Fig. 21 is shown a scheme of an *intermediate evaporator with a two-stage compression.* Such a system is useful when cold has to be produced in two places at different temperatures. The colder vapor flows from the evaporator V_n to the low-pressure cylinder (*NDZ,* Fig. 21) and from there to the high-pressure cylinder *HDZ.* On the way it mixes in container *B* with the warmer vapor which has already produced a cooling action within smaller temperature limits in the evaporator V_h. Both kinds of vapor are forced from the high-pressure cylinder *HDZ* into the condenser *K* and thence flow through the regulating valves R_h and R_n into the evaporator. The scheme as shown comprises a spray condenser of the Riedinger type in which the coil is divided into three zones.

The two lower zones produce the cooling and the condensation and the remaining vapor rises from the separator *A* to the uppermost coil where the fresh cold water produces a most powerful cooling effect. The diagram of this process (Fig. 22) applies to the case of ammonia under the assumption that the cooling water is capable of producing undercooling from 40 to 30 deg. (AA_u). Upon throttling (A_uB_u) to the pressure p_0 in the evaporator V_h, a part of the liquid produces an output of cold (B_uC') equal to $Q_{2h} = 271.8$ cal. The other part of the liquid goes through the second valve (*A'B'*, Fig. 22), and produces in the evaporator V_n a cooling effect (*B'C'*) equal to $Q_{2n} = 287.35$ cal.

During the compression in the low-pressure cylinder *NDZ,* the steam is superheated to 70.5 deg. (*C'D'*) and enters the container *B,* together with the steam from V_h having a temperature of + 10 deg. This produces a combined temperature which

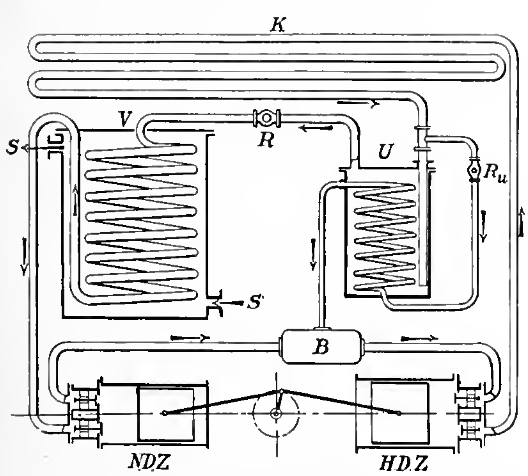

Fig. 23 Refrigeration Machine of Large Size; Two-Stage Compression with Undercooler

may be at first estimated as $t_m = 30$ deg., which is the temperature making it possible to close the diagram with the line C_mD. The two work areas of the diagram comprise then

$$AL_h = 353 - 316 = 37 \text{ cal.}$$

and

$$AL_n = 337.3 - 298.7 = 38.6 \text{ cal.}$$

If we assume a desired output of cold of 500,000 cal. so distributed that 200,000 come from V_n and 300,000 from V_h, then the respective weights of the circulating material are

$$G_h = \frac{300{,}000}{271.8} = 1104 \text{ kg}; \quad G_n = \frac{200{,}000}{287.35} = 696 \text{ kg.}$$

making altogether 1800 kg. From this it appears that the consumption of energy apart from incidental losses is

$$N_h = \frac{1800 \times 37}{632} = 105.5 \text{ hp.}; \quad N_n = \frac{696 \times 38.6}{632} = 42.5 \text{ hp.}$$

or altogether, 148 hp. Hence, the plant delivers an output of cold per hp. of $q_2 = 3380$ cal.

In the ideal process the two rectangles AL_h and AL_n have to be differentiated, and from them may be developed the equation

$$q_0 = 632 \frac{G_h Q_{2h} + G_n Q_{2n}}{(G_n + G_h)\, AL_n + G_n AL_n} = 632 \frac{G_h T_0 + G_n T_2}{(G_n + G_h)\,(T_1 - T_0) + G_n\,(T_0 - T_2)}$$

In our example it appears that $q_0 = 4120$ cal. per hp., which in the present process gives an efficiency, apart from incidental losses, of 82 per cent.

In the container there will be a combined temperature of

$$t_m = \frac{(696 \times 70.5) + (1104 \times 10)}{1800} = 33.4 \text{ deg. cent.}$$

Therefore there must occur in the container a cooling amounting to 3.4 deg. in order to arrive at the assumed initial combined temperature. As regards the dimensions of the cylinder, the specific volumes *d* at the points *C'* and C_n give the necessary information. It is found that

For the low-pressure cylinder: $v = 0.637$ m³ kg.; Total volume = $0.637 \times 696 = 444$ m³/h.

For the high-pressure cylinder: $v = 0.24$ m³ kg.; Total volume = $0.24 \times 1800 = 432$ m³/h.

Both cylinders are therefore of approximately the same size.

In large plants two-stage compression may be used either to produce lower temperatures or to increase the effect when only warm cooling water is available. The undercooler *U* is built in the manner of an auxiliary evaporator to which a small part of the cooling liquid goes through the throttling valve R_u (Fig. 23), while the main part creates a pressure in the closed boiler *U.* The undercooling is therefore produced by the liquid acting as a carrier of cold. Its effect is independent of the cooling water and is so regulated by the valve R_u that only vapor is permitted to reach the high-pressure cylinder *HDZ.*

The article describes also installations where several places (as, e.g., cellars) at a distance from each other are supplied with cold from the same central plant (Entwicklungsformen des Dampf-Kaelteprozesses, Prof. P. Ostertag, *Schweizerische Bauzeitung,* vol. 73, no. 4, January 25, 1919, pp. 33-35, 9 figs. *t*)

STEAM ENGINEERING

Water Circulation in Boilers, A. D. Williams. Discussion of conditions affecting the operation of boilers from the point of view of water circulation, in particular as applied to water-tube boilers. The discussion is of a rather general nature, the most interesting part of it being that dealing with the influence of steam bubbles on the circulation of water. The writer believes that a modification of the design of the Niclausse boiler having the filled tubes set vertically with the manifold at the top may offer almost unlimited forcing possibilities, greatly exceeding the evaporative capacity of existing boilers. On the other hand, such a design with an internal tube in each water tube would be extremely difficult to clean. In any design to secure increased circulation it is important that the course of the water and of the steam bubbles should be arranged in such a manner that they will not impede each other. Theoretically, there should be no limit to the amount of forcing which a vertical-tube boiler can stand except the heat-absorption capacity of its heating surface. With inclined tubes the boiler can be forced only to the extent of turning a sufficient amount of water into steam to occupy the full area of the hottest tubes at their highest point. Any further forcing with this type of boiler will cause it to destroy itself. (*Power,* vol. 48, no. 8, Feb. 25, 1919, pp. 285-286, *pt*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

Spring Meeting

THE program for the Spring Meeting, to be held at Detroit, Mich., June 16 to 19, is to include several subjects which are considered by the Committee on Meetings to be of widespread interest to engineers at the present time. It should be remembered that the meeting will be opened on Monday, June 16, instead of on Tuesday as has usually been the custom, in order to provide for a large number who will probably come from a distance and who could most conveniently leave so as to reach Detroit on Monday and be permitted to return to their homes before the end of the week to attend to business matters.

The Business Meeting will be held on Monday afternoon, followed by the report of the Aims and Organization Committee. This Committee is shortly to have a meeting of its members who come from all parts of the country, representing as they do the different Sections of the Society, at which all the essential features of the report to be presented at the Spring Meeting will be prepared. The work of this Committee is regarded as among the most important of the recent activities of the Society and of far-reaching consequence to the membership and profession generally. Every member who can do so should arrange to be at the meeting on Monday afternoon to hear this report and to participate in the discussion. On the days which follow there will be a session devoted to the all-important subject of Engineering Research conducted by the Research Committee of the Society. Another session will take up industrial relations with reference to recent developments and tendencies, with a view to forming a clearer conception of what the relations must be between employer and employee in order to secure industrial peace. One session is to be under the auspices of the Detroit Local Committee and of the Mid-Western Local Sections, with papers contributed by the several Sections. There will further be several miscellaneous sessions of technical interest to the membership generally.

As would be expected, the Detroit Committee already has extensive plans under way to make the visit a pleasant and profitable one to all who attend. There will be a boat excursion on the Lake on Wednesday, extending into the evening, and one other evening will be spent at the playground of Detroit, Belle Isle; while on the third evening will be a lecture of interest to members and guests alike. Detroit, situated as it is, within reach of the great industrial Middle West, with its wonderful industries which every one wants to visit, ought to draw a large attendance. Every one who expects to go is asked to make early reservations of rooms at the headquarters, Hotel Statler.

The Aeronautical Exposition

In another column in this number will be found a brief account of the remarkably fine aeronautical exposition recently held in New York. The thousands of people who visited the exposition must have realized as never before that we are literally at the threshold of a new era in peace-time development, the ultimate outcome of which can scarcely be imagined.

The exhibits were the more striking in that almost all of the recent progress of the art of flying has been made under war conditions, and consequently was kept secret to a very large extent from the public. What we are seeing now revealed is the hitherto largely hidden accomplishment of three or four years of work.

The forerunner of changes and advancement in our conditions of living has very often been some extension of the means for transportation and communication. Even before this number of MECHANICAL ENGINEERING reaches its readers such an extension may occur through the effort at transatlantic flight by airplane or dirigible or both. If successful, this will be comparable in the matter of expediting travel to the memorable voyage of the *Great Western* in 1838 and the completion of the first transcontinental railroad in 1869.

Proposals for Technical Institutions to Obtain Government-Owned Machinery

The period of reconstruction through which we are now passing presents many problems of infinite possibilities and not the least of these is the disposing of over $2,000,000 worth of machine tools purchased by the Government for its war work.

The law provides that these machine tools must be disposed of so that the Government will obtain the greatest possible return. It is estimated that only about one-third can be utilized in existing Government shops and arsenals and to dispose of the remainder at sacrifice prices would unquestionably demoralize the machine-tool industry, as most machine shops are well supplied at the present time.

To guard against this possibility a bill was introduced in the House of Representatives on February 4, 1919, under the terms of which the Secretary of War would be empowered to lend to trade and technical schools and universities such machine tools as would be suited to their use but which are now owned by the United States Government. The bill makes proper provision for the protection of the Government's interest, as it makes each institution responsible for the proper care and for the return of such equipment when demanded. If this bill becomes a law the Government will thus be relieved of the expenses incident to storage, but its passage is chiefly desirable since it will provide the means for the training of many who might otherwise be deprived of such instruction if dependent upon the present facilities of many of our institutions.

Education of Disabled Soldiers and Sailors

As reported in MECHANICAL ENGINEERING last month, extended provision has been made by the Government and the Y. M. C. A. for the continued education of soldiers who remain in France, both by instruction at vocational schools established at camps and by courses at the universities.

The Government has also made provision for the further education of returning soldiers and sailors who have been disabled in

service. The Federal Board for Vocational Education has been charged by the Vocational Rehabilitation Act with the reëducation of disabled, discharged soldiers, sailors and marines. A central office has been established in Washington with 14 district offices in the following cities: Boston, Mass.; New York, N. Y.; Philadelphia, Pa.; Washington, D. C.; Atlanta, Ga.; New Orleans, La.; Cincinnati, Ohio; Chicago, Ill.; St. Louis, Mo.; Minneapolis, Minn.; Denver, Colo.; San Francisco, Cal.; Seattle, Wash.; and Dallas Tex.

Each district office deals with all cases arising in its own district, the procedure being as follows: A representative of the board, called the "Vocational Adviser," makes a survey of the situation in each case, getting information concerning general education, previous occupation, nature of disability, preference as to future occupation, etc. On the basis of this interview a recommendation is made, and if finally approved by the central office, arrangements are made for training, either in existing educational institutions or in industrial plants. It is the policy of the board to give each man a thorough education, not simply a superficial training in some one process, the length of training varying, of course, with different cases. Assistance is given in securing a suitable position in which is served a probationary period under the direct supervision of the board, in order to determine whether or not a man is successfully placed.

Novel Training Work Directed by Local Section Chairman

There are about 150 men in our Army who were totally blinded in the war and about 75 others whose vision has become so defective that they will need practically the same training as those who are totally blind. The work of training is to be carried on at the Red Cross Institute for the Blind at Baltimore, which will give courses in agriculture, business, commerce and industrial work. Mr. L. W. Wallace, Chairman of the Indianapolis Section of the Society, has just gone to Baltimore to become Director of Industrial Training at the Institute.

The work is being carried on at the Institute in a way that offers a most encouraging outlook for the blinded soldiers. It is not proposed to restrict the training to purely vocational work of elementary character, such as usual at institutions for the blind —work such as broom making, basket weaving, etc. Instead, a careful study is being made of the elements of skilled operations in the industries by the aid of motion pictures and otherwise for the purpose of adapting these operations to the capabilities of blind men and affording them the opportunity to secure important positions commanding good pay. One of the recent subjects to be studied and analyzed is that of core making. The training is conducted at the expense of the Government and the Red Cross.

Classification of Personnel Exhibit

Employers and others interested in personnel work will have an opportunity to examine the methods developed by the Committee on Classification of Personnel in the Army at an exhibit to be shown on the auditorium (third) floor of the Engineering Societies Building, 29 West 39th Street, New York City, April 1 to 12, 1919. The exhibit will consist of a collection of wall charts, forms, photographs and models showing how the Army finds out what men can do best and how it uses that information: how soldiers are trade-tested, and how officers are rated and fitted into place; how the work is checked and supervised, and its results in the war.

The collection is being shown under the auspices of the National Association of Corporation Schools and the United Engineering Society, representing the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers. It was on exhibition for several weeks at Washington, where it excited so much interest that in response to many requests the Adjutant General consented to its display in other cities. Two commissioned officers accompany the exhibit to explain its various features.

Regarding the Use of A. S. M. E. Headquarters for Army Training

One of the satisfactions experienced by the officers and office staff of The American Society of Mechanical Engineers during the war came from the allotment of two of the Society's rooms to the staff of District No. 2 of the S. A. T. C. The relations were most pleasant, and, although the reading room usually enjoyed by visiting members was temporarily given up, we found all members who called to be glad that the Society was able to make this contribution.

Recently the Secretary received the following letters of appreciation with regard to the occupation of the rooms:

My dear Mr. Rice:

On behalf of the Committee on Education and Special Training, War Plans Division of the General Staff in Washington, and on behalf of Colonel Barton and all persons connected with these headquarters during the past four or five months, I wish to thank you for the many courtesies and civilities extended to us collectively and individually by The American Society of Mechanical Engineers during the period that we were the guests of the Society in their home on West Thirty-ninth Street.

Cordially yours,
E. S. L. Price,
Colonel Inf., U. S. A., District Inspector.

My dear Mr. Rice:

Kindly allow me to add my personal thanks to those expressed to you in Colonel Price's letter of February 27th.

During the months that I was District Inspector, of District No. 2, S. A. T. C., and that we were the guests of The American Society of Mechanical Engineers on the eleventh floor of the Engineering Societies Building, we were so kindly and courteously treated and received so many favors and kindnesses from the Society, and from you personally, I want you to know that I individually appreciate it all.

The American Society of Mechanical Engineers rendered the United States a real service during the war, and your gracious kindness will always be remembered by all the War Department's representatives who were fortunate enough to be your guests.

Fraternally yours,
Frank A. Barton,
Lieut.-Colonel, U. S. Army.

A Step in the Direction of Textile Research

There are frequent evidences that need is felt for a larger amount of research work in connection with the industries of this country. A recent instance is the formation of the Textile Research Company, at 34 Batterymarch Street, Boston, Mass. This is an organization by textile manufacturers for the conduct of research or to have research conducted for them along textile lines. Mr. E. D. Walen, late chief of the Textile Section of the National Bureau of Standards, is the manager. Mr. Walen presented a paper at the last Annual Meeting of the A. S. M. E. on the development of a cotton fabric for use on airplane wings, which material proved to be one of the most important factors in the airplane equipment of the Allied Armies.

The need for textile research has been largely brought about through the necessity for using available raw stock and machinery to manufacture materials which have previously been made from specifically selected raw materials. Such a condition has emphasized the advantages to be gained from a more exact knowledge of the properties of raw stock and the effect upon it of various processes. The substitution of cotton for linen for airplane wings, above alluded to, the substitution of cotton webbing for leather straps and many similar accomplishments have demonstrated the feasibility of applying technical information to the manufacture of textiles.

Screw Thread Commission to be Continued

The very important work of the Screw Thread Commission is to be continued for another year. This was made possible on Friday, February 28, when the U. S. Senate passed the bill extending the life of the Commission until March 21, 1920. The promptness with which this bill was passed can be largely at-

tributed to the very favorable report issued by the Congressional Committee on Coinage, Weights and Measures, which, in reviewing the work of the Commission, found that four of the six months granted under the original act were required to compile data and that the real constructive work of the Commission is still ahead.

The chairman of the Commission, Dr. S. W. Stratton, Director of the Bureau of Standards, states in his report that the Commission has held a total of six meetings and that these were attended by 29 representatives of the Army and Navy and 108 manufacturers, as well as representatives of the British Ministry of Munitions and the French High Commission. Before making a final report, he states, the Commission believes that an international conference will be necessary to provide a basis for arbitrary recommendations. However, tentative reports on standards are now being prepared for: terminology, shape of thread, system of coarse screws, system of fine screws, system of small screws, system of pipe thread, system of hose couplings, system of instrument screws, and system of measurement and test.

The Commission also reports that as a result of its studies it has found:

(1) That there is not a common terminology among the users and manufacturers of screws; (2) that there is considerable deviation in many respects from the recognized standard shape of thread on the screws manufactured in the United States; (3) that there is considerable deviation in many respects in the accepted standard of pitch for screws manufactured in this country; (4) that there is not a standard whereby the accuracy of workmanship may be judged; (5) that there is not a standard method of measuring and testing for accuracy; (6) that there are numerous special screws used which are only slightly different, but just sufficiently different to prevent interchangeability; (7) that there is a desire among manufacturers of the United States for an international standard; (8) that an international standard is an absolute necessity if the present shipping and foreign trade program is to be successful; (9) the above conditions have seriously interfered with the naval and military operations during the war, and for many years have constituted a serious hindrance to commerce.

United Engineering Society

Extracts from Treasurer's Annual Report for Year Ending December 31, 1918

The Surplus Account on December 31, 1917, showed a balance of $8,116.10. This amount has been increased by the surplus from the operating accounts during the year of $5,417.33, making a total on December 31, 1918, of $13,533.43. Of this amount $8,000 has been transferred to Depreciation and Renewal Fund, leaving a balance in Surplus Account of $5,533.43.

The Gross Operating Expenses for the year 1918 were $66,505.57. The General Operating Expenses during the year 1917 were $53,791.97, showing an increase for the year 1918 of $12,713.60, partly due to the three additional stories first occupied in October 1917.

The funds available for the Library Board, and spent under their direction during the year, amounted to $28,740.29.

The General Reserve Fund of $10,000 created by the Board of Trustees at a meeting held November 18, 1914, to be available to take care of unforeseen fluctuations of income and outlay, has been preserved intact, there arising no calls on this fund during the year 1918.

The Depreciation and Renewal Fund at the beginning of the year 1918 amounted to $75,037.41. During the year this fund has been increased by the sum of $3,126.37 for interest earned by the investments for this fund during the year and accruals, and by $8,000 added from the surplus at the end of the year, making a total of $86,163.78 on December 31, 1918.

In accordance with the authorization of the Board of Trustees September 26, 1918, the sum of $10,000 was invested in Fourth Liberty Loan Gold Bonds (4¼ per cent).

The following summary shows the amounts of the funds held by U.E.S. as of December 31, 1918:

Depreciation and Renewal Fund Dec. 31, 1917	$75,037.41
Interest on invested funds during the year 1918	3,126.37
Transfer for the year 1918	8,000.00
Total	$86,163.78
General Reserve Fund	10,000.00
Engineering Foundation Fund	303,374.80
Library Endowment Fund	102,559.70

Assets and Liabilities, December 31, 1918

Assets	
Real Estate	$1,947,171.16
Investments Engineering Foundation Fund	303,321.25
Investments Library Endowment Fund	102,297.50
Investments General Fund	85,725.00
Cash	12,869.60
Petty Cash	100.00
Unexpired Insurance	5,958.76
Accrued Interest Receivable	2,392.02
Accounts Receivable, General	542.58
Bills Receivable	12,500.00
Total	$2,472,877.87

Liabilities	
Founders' Equity in Property	$1,947,171.16
Due the General Reserve Fund	10,000.00
Due the Depreciation and Renewal Fund	86,163.78
Due the Library Endowment Fund	102,559.70
Due the Engineering Foundation Fund	303,374.80
Due for Notes Payable A.S.M.E	12,500.00
Due for Accounts Payable	2,090.24
Due for Library 1918, Unexpended Balance	274.26
Due for Library Service Bureau, 1918 Surplus	800.29
Due for Engineering Council, 1918 Unexpended Balance	2,410.21
Surplus (Dec. 31, 1918)	5,533.43
Total	$2,472,877.87

NEW YORK AERONAUTICAL EXPOSITION

The second aeronautical exposition to be held in the United States took place in New York City in Madison Square Garden and the 69th Regiment Armory, March 1 to 15, under the auspices of the Manufacturers' Aircraft Association.

The first exposition, it will be remembered, was held in Grand Central Palace, New York City, a short time before the entrance of this country into the war, and was mainly remarkable in showing how far behind the state of the art was the domestic development of aircraft engineering and manufacture. From this point of view the show this year was a distinctly pleasant surprise to those who have not been able to follow the advances made in America during the past two years.

The show impressed one as a distinctly big undertaking. The two immense structures were filled to overflowing with exhibits, each of which was of interest. Judging by the number of manufacturers, the quality of the product and the evident organization of the plants which could produce the many exhibits shown, the aircraft industry has come to stay in the United States. It has passed the experimental stage, and is now on a strictly commercial basis in the sense that it is capable of producing planes for certain definite purposes.

As regards the purposes themselves, the situation is perhaps less attractive. The majority of planes shown, if not all, were military types with very large power plants, apparently of short life and requiring considerable skill for their operation. It must not be forgotten, however, that the show as it stood represented an industry created for military purposes and devoted 100 per cent to war work. Since the signing of the armistice the industry has not had time to reorganize on a peace basis, but the show may well be considered as the first important step taken in this direction.

There were many planes of various types displayed—from the immense Caproni and Curtiss triplanes and Dayton-Wright bombers to the tiny Ballila plane of the Ansaldo Company (Italian manufacture) and the Messenger plane made in this country by the Dayton-Wright Company. None of these planes, however, can be as yet considered as suitable for what might be termed everyday use. It is significant, however, that so great is apparently the prospective field of application of aircraft that even these planes will doubtless soon be employed for various peaceful purposes. In fact, it was announced at the show that a New York steamship company will use a fast plane to deliver final manifests and other papers to ships at sea which had to leave port before these papers were ready.

There is a certain amount of difficulty in describing the show, in that in other expositions, such as automobile shows, it has been customary for manufacturers to exhibit new devices or constructions previously unknown to the trade or the engineering profession. From this point of view the show was disappointing, as there was scarcely anything displayed the existence of which was not already fairly widely known. This, however, is only natural, as practically all the manufacturers who exhibited had been working for the Government, largely to Government specifications.

The exhibits referred to in the following paragraphs may be considered as among those with which engineers outside of the still narrow field of aeronautical engineering have little or no acquaintance. No attempt is made, however, to give an exhaustive enumeration.

Among the planes shown the big Curtiss triplane developed just before the armistice is noteworthy from the fact that it combines a very powerful structure having great load-carrying capacity with a certain flexibility of the wings which should give it a high speed. In this respect the Curtiss plane differs essentially from the other big triplane shown, namely, the Bi-motor Caproni machine. Another machine possessing the wing-flexibility feature to a still greater extent is the Christmas biplane exhibited by the Cantilever Aero Company, which, in addition to having flexible wings, is also strutless. These two features in combination should give it a very high speed, provided it proves possible to make the whole structure strong enough to withstand the various stresses in the air.

The Gallaudet machine embodies the novel idea of locating the propeller neither in front nor in the rear of the plane, but right into the fuselage so that the propeller hub and the base of the blades are entirely concealed in the streamline cover of the fuselage body, only the acting tips of the blades projecting. It is claimed that such a structure not only materially reduces the head resistance caused by the propeller, but also creates a different distribution of air pressures that is of advantage in obtaining the maximum effect.

As regards power plants, the show did not bring out anything which was not fairly well known before. Several Liberty engines were on the floor, as well as an aero-marine motor, two Hispano-Suiza engines—one of 160 hp. and the other of 300 hp.—a Packard motor, and several Hall-Scott engines. While none of these engines exhibited any mechanical features not well known in the art, they gave an impression of careful workmanship and average good design.

The B. F. Sturtevant Company exhibited an engine with a centrifugal blower attached for purposes of supercompression. Unfortunately, however, the representatives of the company were unwilling to give any information as to its efficiency or the mechanical details of operation of the supercompressor.

In the field of accessories there were numerous interesting exhibits showing the work done by American manufacturers during the war. The Delco Company had on view the ignition system developed for the Liberty engine, and side by side with it the Splitdorf Company exhibited the Dixie magneto developed for multi-cylinder aero engines of the Liberty type.

The Zenith Carburetor Company showed the enormous carburetors built for the big 12-cylinder Liberty engine, while other companies exhibited the various recording and indicating instruments used in military flying.

Of the Government developments, the Navy had probably the most interesting exhibit, comprising both planes and their armament, including the Lewis gun. A dirigible balloon, a stationary balloon and an exhibit of fabrics in their manufacture revealed the part taken by aerostatics in our military preparedness. On the whole, however, the visitor at the show carried away an impression that while American aeronautics was probably not behind that of England and France at the present moment, it was certainly far behind at least that of the first-named of these countries in lighter-than-air engineering developments.

Several meetings of engineering societies and other bodies were held during the show, the most interesting of which was that of the Aeronautical Society of America, at which Capt. W. R. Schroeder, of the Technical Service, Aircraft Section, War Department, gave a brief talk on high-altitude flying.

Captain Schroeder told of his flights to determine the ceilings of the various types of machines, in the course of which he made what is probably the world's record for altitude, namely, an actual ceiling of about 29,000 ft. This was possible only by using oxygen both for the engine and flier in the last few thousand feet.

A highly significant feature of the last attempt in which the record altitude was reached lay in the following fact: Captain Schroeder rose in a westerly direction, so governing his flight as to come down in a volplane as near as possible to the place from which he rose, which was McCook Field, Dayton, Ohio. He

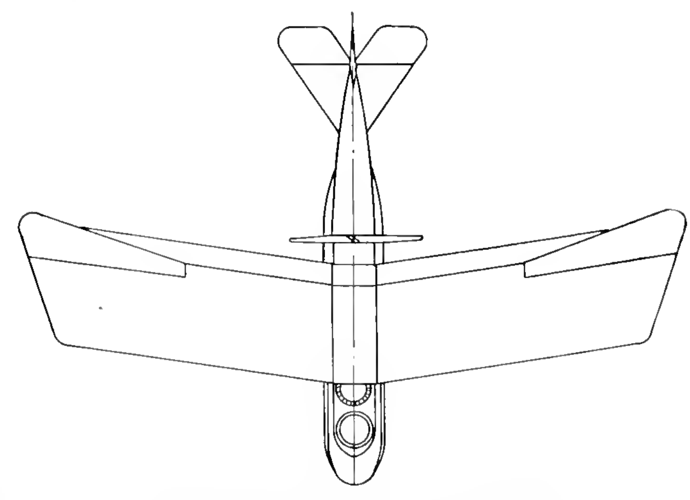

Diagram of Gallaudet Aeroplane

went up for a period of 85 min. and did not give up until all of his gasoline was exhausted. It took him 20 min. to come down in a volplane with the motor dead from the altitude which he reached, and the significant point is that he landed nearly 200 miles east of Dayton, which shows he either encountered extremely powerful winds at the high altitude, or that in some way his flight was affected by some other factor not yet determined—possibly the rotation of the earth. In any case this confirms the statement previously made by Lord Montague de Beaulieu to the effect that in long-distance and high-altitude flights it is very important to take into consideration the winds prevailing at the altitude where the flight is made.

The general impression made by the show is that the American aeronautical industry has come to stay. Apparently it has not yet developed an actual commercial aeroplane, which could not be expected, however, since up to a few months ago it has been working exclusively for our military establishment; but such products as have been shown in the way of planes, engines, and accessories represent a high grade of workmanship and an earnest effort at producing careful designs.

Washington Announces Abandonment of Neville Island

The War Department has officially abandoned the $50,000,000 Neville Island project. A recent announcement of the Department states that the buildings erected there are to be torn down and the island restored to the original owners, but denies the report that the plant is to become the principal ordnance storage depot for the Eastern United States. It will, however, be used temporarily for storage purposes. The Neville Island plant was one of the largest undertakings of this kind during the war. It was intended chiefly for the production of heavy artillery, as no guns of less than 14 in. were to have been built there. Congress appropriated $40,000,000 for the plant and a total appropriation of $140,000,000 had been asked for.

ENGINEERING COUNCIL

Extracts from Annual Report

ENGINEERING COUNCIL has completed its second year. Notable in the year's history are its service to the Government in connection with the German war, the creation of the Engineering Societies Employment Bureau, the establishment of a Washington office, the appointment of a committee on Licensing of Engineers, and the admission of an additional member society. Through visits made by the Secretary mutually helpful relationships with engineering societies in twenty-five or more localities were established.

Engineering Council held six regular meetings beginning with the Annual Meeting, February 21, 1918, and one special meeting on November 21, all in Engineering Societies Building, New York. There was no change in the officers as elected at the beginning of the year: J. Parke Channing, Chairman, Harold W. Buck, First Vice-Chairman, George F. Swain, 2nd Vice-Chairman, Alfred D. Flinn, Secretary. For the year's expenses the sum of $16,000 was provided, and there remained unexpended January 1, $2400. Particulars regarding the activities of the Council's various committees follow.

Executive Committee. Eight meetings were held. The principal business of most of these meetings was the preliminary study of matters to be brought before Engineering Council so as to economize time at Council meetings.

January 6, 1919, an urgent meeting was called to determine what action Engineering Council could take concerning the sudden dismissal, by the Public Service Commission for the first District of New York, of approximately 350 engineers and assistants engaged on subway construction.

January 28 a meeting was held to instruct Council's Washington representative as to his course of action before committees of Congress on matters demanding immediate attention, especially propositions relating to a National Department of Public Works.

Rules Committee. This committee prepared and submitted for adoption at the February meeting, 1918, "Rules for Guidance of Business" and "Rules for Admission of Additional Societies to Membership in Engineering Council." The latter rules were subsequently duly approved by United Engineering Society and the four Founder Societies. A tentative list of societies eligible for membership was prepared and sent to all representatives. From this list six societies were selected for immediate consideration and three ultimately elected, subject to approval by United Engineering Society and the Founder Societies. These approvals were all received by December 1918.

Public Affairs Committee. This committee made preliminary investigations which led to the appointment of a Patents Committee and a Committee on Licensing of Engineers. It presented a resolution to the December meeting of Council, requesting favorable attention of Congress to land reclamation on a large scale as a "reconstruction" measure under thorough engineering supervision. This resolution was adopted by Council and later followed up by the Washington representative. The committee also reported upon the allocation of labor and equipment for production of war materials, an "Institute for History of Science" as a branch of the Patent Office, engineering experiment stations at Land Grant Colleges, assistance to members of faculties of colleges of pure and applied science engaged on war work by relieving them of certain routine duties; no activity was undertaken by Council in any of these matters.

American Engineering Service devoted its energies and those of its small staff almost exclusively to aiding governmental departments in procuring technical men for war service. With the assistance of the four Founder Societies and other engineering societies, classified records of many thousands of engineers were assembled and from these, in response chiefly to more than two hundred requisitions from thirty principal and subordinate governmental departments, names of approximately four thousand engineers were supplied, all carefully selected. Many interviews between Army and Navy officers and candidates were arranged and other services rendered. Besides, a number of engineers were assisted in finding engagements in civilian work and several offices were aided in obtaining engineers. This committee was disbanded at the end of November on account of the armistice and succeeded by Engineering Societies Employment Bureau.

War Committee of Technical Societies. During its latter months the committee had 22 members representing 11 societies. Financial support was provided by Engineering Council. The Naval Consulting Board provided offices in New York, and for the last few months, also in Washington, together with frank for mail and other assistance. This committee was closely allied with the Naval Consulting Board, and, beginning in the summer of 1918, also with the Inventions Section of the Army General Staff; the latter provided the services of Capt. Scott as secretary. On account of the armistice, this committee ceased to exist December 31. During the year this committee aided the Army and Navy in examining 135,000 inventions and suggestions for war devices. To stimulate intelligent solution of war problems, the committee with the Naval Consulting Board issued two pamphlets, the first entitled "The Enemy Submarine" and the second "Problems of Airplane Improvement." Before the bulletins were issued 0.4 per cent only of suggestions received had any value; afterward, 4.7 per cent. One of the most important services rendered was to demonstrate to the War and Navy Departments how the civilian engineers of the country could be mobilized for the aid of the Government in war, and to establish direct communication for this purpose between the departments named and the engineering societies.

Fuel Conservation Committee. This committee has collaborated with the Bureau of Mines and the Fuel Administration, one of its members being Advisory Engineer to the latter, and its Secretary, Chief Mechanical Engineer to the former. This committee also cooperated with committees of various engineering societies, working along similar lines in many parts of the country. Its work will be continued.

Patents Committee. Appointed so that Engineering Council might have a share in endeavors to improve patent-law practice and the organization of the Patent Office. This committee interlocked with a similar committee of National Research Council and accepted the able report of the latter. This report, recently made public, proposes the following changes in the patent system:

1 Establishment of a single Court of Patent Appeals
2 Separation of Patent Office from Department of Interior
3 Increase in force and salaries of Patent Office
4 Modification of that section of the law granting compensation for infringement of patents.

Water Conservation Committee. Was created to deal with questions concerning the utilization and control of water for various purposes in all parts of the country. It has defined its general policies and is prepared to furnish broad information on large problems, particularly to committees of Congress, to State Legislatures, or to governmental departments. The committee proposes to deal with those facts of engineering which are beyond reasonable controversy.

Engineering Societies Employment Bureau. Following the termination of hostilities, Engineering Council at its special meeting November 21, established an Employment Bureau with the secretaries of the Founder Societies as a Board of Directors. The Bureau took over the staff and equipment of American Engineering Service at the end of November. From the beginning of its work to February 15, it has received applications for positions from 1375 engineers in all branches of the profession. For a total of 200 applicants employment has been found. The services of the Bureau are not restricted to members of the engineering societies represented in Engineering Council, but nonmembers are expected to present letters of introduction from a member. Extensive efforts have been made to inform employers of engineers of the Bureau's resources for serving them. No charge is made for services.

Reconstruction Committee. At the November meeting of Council, in order to deal with several matters falling under the head of "reconstruction" and especially to work out the details of the organization and personnel of the proposed National Service Committee, the Reconstruction Committee was appointed. At meetings held November 29 and December 16, 1918, it selected the personnel of the National Service Committee and determined sufficient elements in its organization to permit that committee to begin work before the end of the year. It was understood that the chairman should be the executive head of the National Service Committee with reasonable independence in action for the effective performance of his duties, and that the other members of the committee would be expected to serve principally in the capacity of an advisory board to the chairman. January 28, the Reconstruction Committee held a joint meeting with members of the Public Affairs and National Service Committees to discuss the establishment of a National Department of Public Works.

National Service Committee. At the November meeting of Council, representative Philip N. Moore presented a communication entitled "Representation of Engineers at National Capital." From this proposal grew the National Service Committee with a permanent representative and office in Washington, which was established through the agency of the Reconstruction Committee. The office is Room 502, McLachlen Bldg., 10th and G Streets, Washington, D. C. The committee has taken up a number of subjects with committees of Congress and the departments. Most important among these have been (1) Land Reclamation, following resolution adopted by Council November 21 (Tyrnes Bill S. 13651, proposing an appropriation of $100,000,000 for reclamation of arid, swamp and stump lands); (2) National Public Works Department in connection with Kenyon Bill, S. 5397, and hearings before Committee on Education and Labor to which this bill was referred, and the Committee on Public Buildings and Grounds which was investigating certain work of the Army Construction Division.

License Committee. There is active interest in several states in proposed legislation relating to the licensing of engineers, and a number of inquiries from engineering societies have been referred to this committee. The License Committee is endeavoring to coordinate and direct these activities.

Americanization Committee. Is prepared to coöperate with the Division of Americanization in the Department of Interior and with the National Americanization Committee. Since engineers have more or less direct contact with large bodies of foreign-born employees, it is expected that they will render substantial help in this important work. An instructive report has been written by the committee summarizing the present status of Americanization activities.

Publicity Committee. Is a committee of volunteers to help the Secretary in some of the publicity work, principally in preparing and distributing material for publication in technical journals and daily newspapers after authorization by Council. Besides this New York committee, there are twenty-six correspondents in engineering centers scattered over the country to aid in the transmission of information between Engineering Council's office and local societies of engineers.

American Academy of Engineers. Organizers of the proposed Academy sought the support of Engineering Council in securing a charter from the Federal Government. After several conferences and mature deliberations, Engineering Council declined to support the bill before the House of Representatives.

Classification and Compensation of Engineers in Railroad and Government Employment. A communication prepared by Engineering Council addressed to the Railroad Wage Commission was presented by the Secretary in person to a meeting of that Commission in Washington, February 25, 1918. This matter was pursued from time to time, and with that of the compensation of engineers in Government employment is now in the hands of the Public Affairs Committee.

Reconstruction. Under date of November 15, a letter was sent to President Wilson regarding the appointment of engineers on the proposed Federal Reconstruction Commission. To this letter the President replied briefly under date of November 20, that existing instrumentalities were being utilized. Letters to the governors of all states, urging the inclusion of engineers in any reconstruction commissions which might be appointed, were sent out in February 1919.

Field of Activity of Engineering Council was outlined at the November meeting by carefully prepared preambles and resolutions which have been generally announced to engineering societies.

Information to Federal and State Authorities. At its November meeting, Engineering Council expressed its attitude in the following resolution: "That Engineering Council should be prepared to furnish to Federal and State authorities information regarding engineering and allied facts and opinions which are beyond the field of controversy, and shall take such steps as are consistent with the standing of the societies it represents to inform such Federal and State authorities of its willingness so to act."

Smith-Howard Bill for the establishment of engineering and industrial research stations at educational institutions in all the states was discussed at length. While favoring research when properly carried on, Engineering Council refrained from expressing opinion on the proposed legislation in the form in which it was brought to its attention. Council's Washington representative was directed to attend a meeting January 6, of delegates from organizations interested in redrafting the Smith-Howard Bill; a report of this conference was submitted. The parties interested are still widely at variance and there is nothing further for Council to do at present.

Curricula of Engineering Schools. The subject of changes in curricula of engineering schools was discussed in a general way at more than one meeting. It was brought formally to the attention of Council by resolutions adopted by the War Committee of Technical Societies at its final meeting, suggesting that as a measure of future military preparedness engineer students in the large universities and colleges should receive instruction in the art of war. A committee was appointed December 19 to study this matter. This committee has reported.

Committee of Engineering Council Considering Engineers' License Laws

ENGINEERING Council has appointed a committee on Licensing of Engineers, of which Theodore L. Condron of Chicago is chairman and the other members, 12 in number, are representative of different sections of the country. This bids fair to become one of the most important of the Council's committees in view of the active interest which engineers are taking in various parts of the country in projects for state legislation to regulate the practice of engineering.

Engineers' license laws are already in force in Florida, Louisiana and Illinois, and bills for this purpose have been introduced or proposed in California, Colorado, Nevada, Washington, Iowa, Michigan, Ohio and Indiana. The license law in Florida requires the registration and licensing of all professional engineers practicing in the state, whereas the law in Illinois is limited to the registering and licensing of structural engineers only.

The Louisiana law is "to regulate the practice of civil engineering and surveying; to create a State Board of Engineering Examiners, and regulate the fees and emoluments thereof, to prevent the practice of the said callings or professions by unauthorized persons."

The great changes in conditions which engineers with all other classes of the community face as a result of the war make it desirable that the question of the licensing of engineers should be investigated broadly and impartially by a committee representative of various sections of the country and of different branches of the profession.

Engineering Council, therefore, has divided the country into districts and the different members of its committee, each assigned to a district, are undertaking to gather information regarding the laws in force or proposed and the bearing which they may be expected to have on the welfare of both the engineer and the public. Among the questions now being investigated are the following:

1 Should state laws be enacted requiring definite qualifications for the practice of specific branches of engineering? If so, what branches of engineering work should be included?

2 Should such laws provide for the examination of candidates and formal license to practice, by a state board of duly qualified engineers?

3 Can the dangers be obviated that such legislation would operate to confine engineering work within state boundaries and that it would ultimately be used to raise state revenue by a special tax on engineers?

4 If the legislation above outlined is found to be inadvisable, are other laws or methods possible by which those employing engineers in specific branches of work may be more effectually aided in ascertaining their competence?

In this connection attention should be called to the thorough investigation of the question of a state license law for engineers made four years ago by an expert commission in Pennsylvania. This commission of five eminent engineers was appointed by the governor under authority of an act of the legislature. The commission held public hearings in different parts of the state—and collected a large amount of testimony from engineers representing all branches of the profession. While the commission at the outset apparently was inclined to favor the general proposition of state regulation, its final reports opposed any legislation for the control of the work of engineers engaged in private industry and recommended only examinations for engineers engaged in various branches of public work.

Other Engineering Council Activities

An invitation has been extended to various engineering societies by the Engineering Council to attend a conference in Chicago, April 23 to 25, to discuss the advisability of a National Department of Public Works. There appears to be promise of the passage of a bill by the next Congress for the establishment of such a department if the different societies interested will unanimously agree on and support such a measure.

A new committee about to be appointed by the Council relates to the Classifications and Compensation of Engineers, having as its object the securing of better conditions for employment of engineers, including their classification into grades and a statement of what it is considered should be the relative salaries of the different grades. It is proposed to consider:

1 Engineers engaged in civil, mechanical, electrical and railway engineering, etc.

2 Engineers in Government (national) employ.

3 Engineers in municipal employ.

Still another activity which has recently developed relates to International Affiliation of Engineers, a committee for which has been appointed with Charles F. Loweth as chairman. The primary object is to secure closer coöperation between the engineers and engineering societies in this country and those of Canada.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

IN discussing the relation of the Mechanical Engineer to his work in conducting and assisting research, the subject naturally divides itself into two parts: The relation of the individual engineer and the relation of the collective engineer, that is, the Society to which the engineer belongs.

The relation of the individual engineer is one of action and one of encouragement. At present there is, and in fact at all times there has been, a great need for those who would devote themselves to the determination of the unknown, for pioneers to go into the regions of science and lay hold of some of its domain for the use of their fellows. That need is great today since the small chance for a large financial reward and the necessity for close attention to details has taken many men who have started life as investigators out into the more productive fields of commercial life or science after a few close years of research work.

The value of the investigator is quite evident to many manufacturers, and men who have shown ability in their work on large general problems have, on account of greater financial returns, given up this work to the small special problems of commercial plants. It is in this commercial work that the individual engineer can be of great assistance in endeavoring to carry his problems of research to a general conclusion, rather than stopping when a particular or the partial commercial result of his investigations has been attained. Where possible, he should endeavor to influence those under whom he is working to see the necessity of making the investigation general and then giving the result to the world.

Of course many investigations are undertaken for commercial reasons, and the results of such investigations are not to be made public until the commercial purpose for which they were started has been protected. This is undoubtedly the reasonable point of view, although a broader plan would be to open up to the world the results of all research; but this is not to be expected under present conditions. According to the daily press a convention of dental societies agreed to make all special processes or inventions resulting from research the property of the profession at large, giving to all a free use of these results. This broad and altruistic view is to be commended and desired, but in ordinary business it is feared that little support would be given by commercial organizations if there was not some possible gain for them in view.

The individual engineer should realize the importance of research since the physical data which he uses every day have been the result of the researches of others, and for that reason he should endeavor to emulate the action of such, in not being satisfied to use rule-of-thumb methods in new problems, but when data are lacking, he should proceed by research to ascertain the necessary information. He should, where possible, endeavor to encourage others in this field of work. One of the great needs at present is for men with the training, enthusiasm and disinterestedness of investigators and a proper attitude of the individual engineer to encourage young men to enter this field.

Turning now to the interest of the engineers in collective units, I feel that one function of an engineering society is to aid those engaged in research by the six methods which have been undertaken in the present program of the Research Committee of The American Society of Mechanical Engineers, and in addition to these six, the Society should give financial aid to those engaged in general work.

To aid the investigator the Committee is planning to bring together information regarding the researches in various parts of the country, informing the investigators and the engineers of the country about methods and subjects of research, giving information which will bring together those who are interested in the same problems for conference and coöperation, and preventing unnecessary duplication of work. The spirit of coöperation is an important one to foster and by coöperative endeavor great work can be done.

To encourage research the Society should organize committees to superintend actual work. In regard to subjects of general interest, and where present data seem to be in conflict, these committees could investigate the problems further for the purpose of harmonizing the data or by proving which of them are correct. In many cases this work may have to be financed by the Society, while in other cases small grants may be all that are necessary. By its clearing-house methods for research information the Society will discover those requiring assistance, and by a small aid in the time of need, certain researches may be carried to a conclusion, and without such aid they would remain incomplete.

As a duty to the profession the Society should collect and publish the results when such results are not published. It should endeavor to have reports made in a regular way, and even though the results of research have not been published in a limited way, it is advisable to abstract these for publication in our Journal for the benefit of the whole profession.

To help those who have research problems to solve but who have no equipment or other facilities, the Society, through its Research Committee, can aid in bringing together the man with the problem and the man with facilities for research. There is much equipment which is idle for the lack of suitable problems on which work is to be done. It is hoped that this clearing-house method will aid in utilizing some of the equipment.

To those about to undertake research a survey of the present conditions of the field to be covered is necessary, and a study should be made of the literature of this field of endeavor to discover this condition. Bibliographies are necessary, and in many cases persons are situated at such a distance from large libraries that this work could not be done by them. The Society can come to the aid of such persons in preparing for them bibliographies founded on careful searches in the large library of the United Engineering Society. In this way the whole Society can aid. Of course it is realized that this should only be done for those who are working on a general problem and also for a research which is to be given to the profession at its conclusion. Where the research is of a commercial nature, it would be manifestly unjust and improper to give such aid.

To recapitulate, I feel that the activities of the individual engineer should be devoted to carrying on research to such a degree that results would give a general relation rather than the solution of particular problems, that he should endeavor where possible to have these results made public, that he should encourage others in the field of research, and should endeavor to lead those with the proper preparation of spirit to enter such fields. The engineer in a collective sense, represented by the Society, should aid research by financial support of those needing it, by the preparation of bibliographies, by the publication of research problems and of information regarding research equipment for the purpose of bringing it to the knowledge of those who have not the equipment for a problem at hand, by publishing news relating to research in progress, and by publishing research results.

ARTHUR M. GREENE, JR., *Chairman.*

Reports Upon Research

A—Research Results

Electricity 1-19 Lightning Protection. Circular No. 1 of Engineering Experiment Station, Purdue University, Lafayette, Ind. A collection of facts relative to lightning protection.

Hydraulics 1-19 Flow of Water Through 1½-in. Pipes and Valves, Frederick W. Greve, Jr., Purdue University,

Lafayette, Ind. From Bulletin No. 1, Engineering Experiment Station.

CONCLUSIONS. The loss of head can be represented by equation $h = MQ^n$ for valves and pipes with the exception of check valves at low velocities. In the above formula h = loss of head in feet and Q = cubic feet flowing per second. The values of M and n are given in the Table 1.

TABLE 1 VALUES FOR USE IN LOSS-OF-HEAD FORMULA

Description.	M	n
1½-in. pipe per 100 ft.	831.0	1.817
1½-in. check valve for Q above 0.043 c.f.s	1276.3	1.944
1½-in. gate valve:		
0.2 in. rise from seat.	10067.2	1.946
0.45 in. rise from seat.	1854.2	1.946
0.65 in. rise from seat.	818.4	1.901
1.00 in. rise from seat.	476.3	1.865
Wide open.	363.5	1.843
1½-in. globe valve:		
One turn open.	5257.4	1.947
1.5 turns open.	1703.7	1.881
2.0 turns open.	1379.7	1.940
3.0 turns open.	1041.9	1.922
5.5 turns open (wide).	953.7	1.915

Fig. 1 shows arrangement of apparatus used in the experiments and Fig. 2 a logarithmic diagram of loss of head and quantity.

B—RESEARCH IN PROGRESS

Air 1-19 The Flow of Air Through Orifices. Ohio State University, Columbus, Ohio. Prof. W. T. Magruder.

Automotive Vehicles and Equipment 1-19 Investigation of Oil Constituents in the Crankcases of Automobile Engines After Long Usage. Armour Institute of Technology, Chicago, Ill. Prof. G. F. Gebhardt.

Electrochemistry 1-19 Fixation of Atmospheric Nitrogen by High-tension Currents. Engineering Experiment Station, Purdue University, Lafayette, Ind. Address Director C. H. Benjamin.

Electric Power 1-19 The Efficiency of Electric Ranges. Engineering Experiment Station, Purdue University, Lafayette, Ind. Director C. H. Benjamin.

Fuel Utilization 1-19 The Process Underlying Carburetion. Ohio State University, Columbus, Ohio. Prof. W. T. Magruder.

Fuel Utilization 2-19 Standardization of Gasoline Carburetors. Engineering Experiment Station, Purdue University, Lafayette, Ind. Director C. H. Benjamin.

Heat 2-19 Heat Transmission Through Various Building Materials, Thickness ½ in. to 4 in. Armour Institute of Technology, Chicago, Ill. Prof. G. F. Gebhardt.

Hydraulics 1-19 Friction—Coefficients of Pipe Friction and Constants of Orifices for Pipe Sizes from Two to Four Inches. Armour Institute of Technology, Chicago, Ill. Prof. G. F. Gebhardt.

Internal-Combustion Motors 1-19 Test of 14-in. by 18-in. Single-Acting Tandem Buckeye Engine with Natural Gas Under Varying Conditions. Ohio State University, Columbus, Ohio. Prof. W. T. Magruder.

Lubrication 2-19 A Research on Lubricating Oils. Committee on Lubricating Oils, Bureau of Standards, Washington, D. C.

The program of the Committee is made out under the following heads: 1, General Purpose; 2, General Statement; 3, Some Specific Problems; 4, Engines and Engine Tests Methods; 5, Theory of Lubrication; 6, Routine Tests; 7, Special Laboratory Examinations; 8, Oils for Investigation; 9, Effect of Adulteration; 10, Regeneration of Used Oils.

Metal Manufactures, Miscellaneous 1-19 The Strength of a Fillet Experimentally Determined. Ohio State University, Columbus, Ohio. Prof. W. T. Magruder.

Properties of Engineering Materials 1-19 Alloy-Steels at Varying Temperatures from — 100 to 1500 Deg. Fehr.; Tensile Strength Yield Point, Elongation and Reduction of Area. Armour Institute of Technology, Chicago, Ill. Prof. G. F. Gebhardt.

Road Materials and Equipment 1-19 A Survey of Road Materials of Indiana. Engineering Experiment Station, Purdue University, Lafayette, Ind. Director C. H. Benjamin.

Railroad Rolling Stock and Accessories 1-19 (1) Testing of Street-Railway Car-Axle Boxes, 4½ in. by 8 in. on Their Own Axles. (2) Test of Freight-Car Boxes 5½ in. by 10 in. on Their Own Axles. Ohio State University, Columbus, Ohio. Prof. W. T. Magruder.

Railroad Rolling Stock and Accessories 2-19 Force of Impact of Flat Wheels on Rails. Engineering Experiment Station, Purdue University, Lafayette, Ind. Director C. H. Benjamin.

Railroad Track and Signals 1-19 The Breaking of Steel Rails at Low Temperatures. Engineering Experiment Station, Purdue University, Lafayette, Ind. Director C. H. Benjamin.

Steam Power 1-19 Influence of Back Pressure on the Performance of Small High-Speed Steam Engines. Armour Institute of Technology, Chicago, Ill. Prof. G. F. Gebhardt.

Transmission 1-19 Determination of Belt Slips and Creeps. Belt 4 in. Wide. Armour Institute of Technology, Chicago, Ill. Prof. G. F. Gebhardt.

Transmission 2-19 Bearings—Coefficient of Friction of Annular Ball Bearings Subjected to Combined End and Radial Thrust. Armour Institute of Technology, Chicago, Ill. Prof. G. F. Gebhardt.

Transmission 3-19 Tests with Multiple-Bearing Testing Machine with Speeds at 400 R.P.M. and Under Loads of 15,000 Lb. for 4-in. Shifts. Ohio State University, Columbus, Ohio. Prof. W. T. Magruder.

C—RESEARCH PROBLEMS

During the past month the Research Committee of The American Society of Mechanical Engineers has received word from a number of laboratories that they would gladly help in the work of the Committee if they knew of problems which are worth while. They are willing to work, they have good equipment, but they do not know just how to aid. It is hoped that those who have research problems of a general nature will send in their problems to the Committee, so that these may be published in MECHANICAL ENGINEERING, and those prepared to undertake work can communicate with those having problems.

D—RESEARCH EQUIPMENT

Apparatus 1-19 Screw Threads—Testing Device for Pitch. Communication B514, Gage Section, Bureau of Standards, Washington, D. C. February 10, 1919.

The Gage Section of the Bureau of Standards has installed in its laboratory devices for measuring the pitch of straight and tapered screw-thread gages. The communication describes the construction of the apparatus, giving a list of the parts required. The general scheme of the apparatus is to advance the gage one pitch by means of a micrometer screw, and to determine whether or not the gage has been advanced exactly one pitch by the movement of an image from a lens at the end of a multiplying indicating bar, the other end of which fits into the threads of the gage. The image is reflected by two prisms to a ground glass in front of the apparatus, and when this image is brought to the same point as that occupied before movement, the gage has been advanced one pitch. The construction of the apparatus is seen from Figs. 3 and 4.

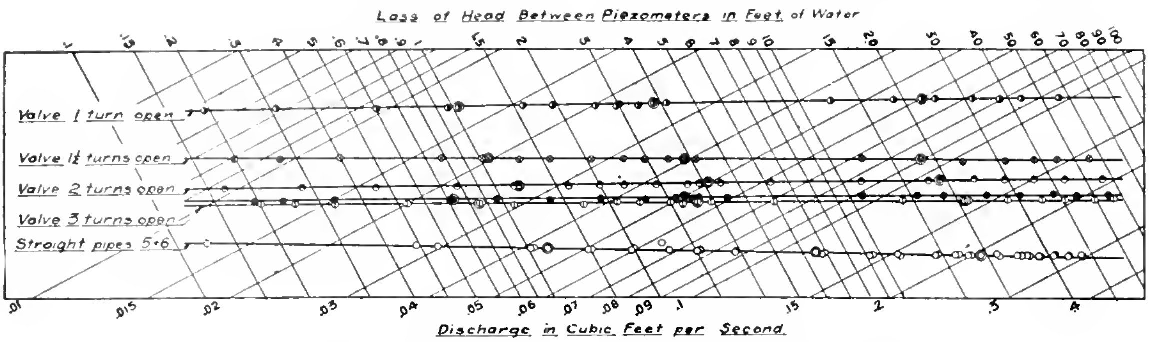

FIG. 2 LOGARITHMIC DIAGRAM OF LOSS OF HEAD AND DISCHARGE

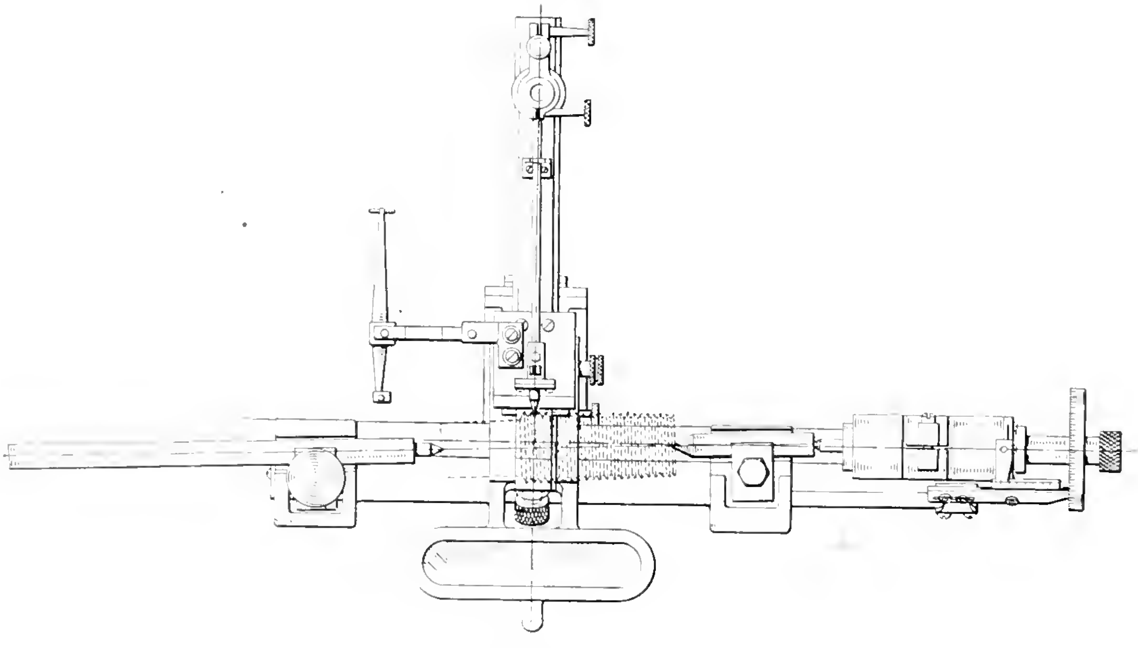

FIG. 3 PLAN OF BUREAU OF STANDARDS APPARATUS FOR TESTING PITCH OF SCREW-THREAD GAGES

Apparatus 2-19 Screw Threads Apparatus for Measuring Profiles of Screw Threads. Communication B510, Bureau of Standards, Washington, D. C. December 9, 1919.

The Bureau of Standards has built and installed in the Gage Laboratory apparatus for examining the profiles of screw-thread gages. The principle of the apparatus is to cast a shadow from the profile of the gage through a lens to a mirror placed about 10 ft. above the gage, and to reflect this shadow back to a point near the projecting apparatus. The magnified profile can then be studied and measured. This communication describes the apparatus necessary for the complete installation, and indicates what may be bought in the open market.

Apparatus 3-19 Length Measurements. Communication B508, Gage Section, Bureau of Standards, Washington, D. C. November 12, 1918.

The Gage Section of the Bureau of Standards has prepared a communication on the Precision of Length Measurements. The communication discusses:

A Total Length of Line Standards
B Calibration of Intervals
C Length of End Standards
D Notes on Micrometer Microscopes.

The communication then gives the history of length standards in a brief form, tracing the yard, the toise, the U. S. Standards and the metric standards. The communication refers to Circular No. 2 of the Bureau of Standards, and reprint No. 256 of the Bureau Bulletins for the method of comparison with fundamental standards, and also to the Hansen Calibration of Intervals as given in *Trav. et Mem. du Bur. Int. des Poids et Mesures*, 5-1886. For length of end standards it refers to article by Fischer in *Bulletin of Philosophical Society of Washington*, vol. 13, p. 241. For the calibration of micrometer microscopes it refers to the Bureau of Standards, vol. 10, p. 375, Reprint No. 215.

Purdue University 1-19 Farm-tractor and motor-truck testing plant. Plant for the standardization performance of tractors in a similar way to standardization of locomotive and automobile performance by the same laboratory. Purdue University, Lafayette, Ind. Director C. H. Benjamin. (See MECHANICAL ENGINEERING, March 1919, p. 295.)

Ohio State University 1-19 Belt-testing machine in process of design. Pulleys to 60 in. in diameter and speeds to 10,000 ft. per min.

E—Research Personal Notes

General 1-19 Coöperative Research.

The Experiment Station of the University of Illinois is undertaking a study of hot-air furnaces and hot-air heating systems using these furnaces. The unknown problems of this system of heating are numerous. Many of the present data are based on experiments made years ago, and much practice and many methods of installation are based on trade practice and not on

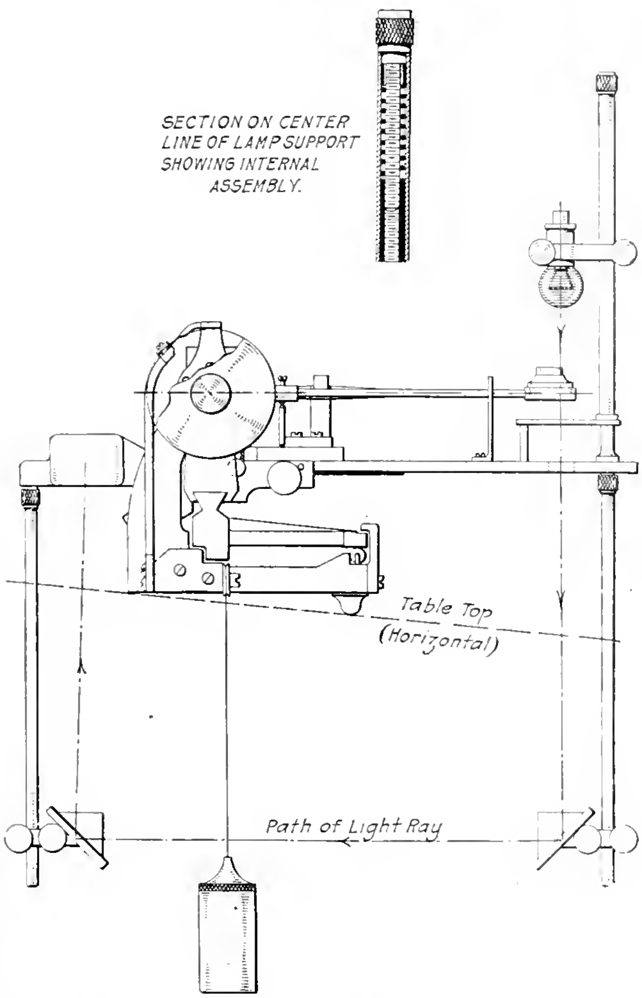

Fig. 4 End Elevation of Apparatus Shown in Fig. 3

scientific data. Such problems as heat losses, velocities, temperature changes, combustion, and multiplicity of risers from one heater are being studied by constructing within the laboratory a model of a house of several floors. In this way the results from actual installations are expected. This work is being done by the Experiment Station, using a grant of funds from an Association comprised of hot-air-furnace manufacturers.

This problem is unique in that it will not only solve many disputed and unknown questions relating to an important system of heating dwellings, but it indicates what may be done by coöperation.

It is one of the hopes of the Research Committee that those who are interested in obtaining definite information relating to problems in their field of activity will combine and make a joint investigation. When the individual companies have not the necessary equipment, personnel and capital for such work, they may, by coöperative effort, arrange with some one having the equipment to carry on the work, the united industries bearing the expense. By this united effort the work may be carried on in a disinterested way, and the results be removed from any suspicion of commercial influence or bias.

Table 2 Diameter Modification of United States or British Standard Whitworth Threads for Interchangeability

Pitch		Change in effective diameter for interchangeability, in.	Difference in full diameter required for assembly, in.	
Threads per inch	Inches	Minus on bolts or plus on nuts	U. S. nut B. S. W. bolt	B. S. W. nut U. S. bolt
20	0.0500	0.0024	0.0029	0.0019
18	0.0556	0.0027	0.0032	0.0022
16	0.0625	0.0031	0.0037	0.0025
14	0.0714	0.0035	0.0042	0.0028
12	0.0833	0.0041	0.0048	0.0034
11	0.0909	0.0045	0.0053	0.0035
10	0.1000	0.0049	0.0059	0.0039
9	0.1111	0.0054	0.0065	0.0043
8	0.1250	0.0061	0.0073	0.0049
7	0.1429	0.0070	0.0083	0.0057
6	0.1667	0.0082	0.0098	0.0066
5	0.2000	0.0098	0.0116	0.0080
4.5	0.2222	0.0109	0.0129	0.0089
4	0.2500	0.0122	0.0145	0.0099

If the Research Committee of The American Society of Engineers can bring about a combination of any interests for coöperative research, it will be very glad to act as the intermediary for this purpose.

General 2-19 Research in Engineering Laboratories.

During the past month the Research Committee has communicated with a large number of the engineering laboratories of our educational institutions, and most of the engineering institutions have reported that war work has so interfered with their regular schedule that little or nothing is being done. However, they expect that after next summer work will again become normal and research investigations will be carried on.

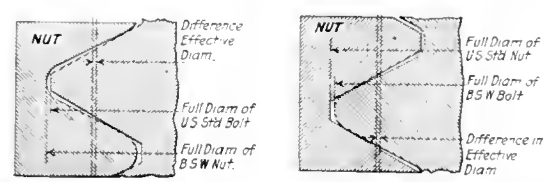

Fig. 5 Interchangeability of U. S. Standard and Whitworth Threads

Apparatus 1-19 Screw Threads—Interchangeability of U. S. Standard and British Standard Whitworth Threads. Bureau of Standards, Gage Section, Sept. 21, 1919. Communication B512.

The Bureau of Standards has issued a table showing that by a slight modification of the diameter of the U. S. or of the Whitworth thread or by a change in both, interchangeability can be secured without changing the form of either. Contact occurs near the crest of the Whitworth thread form or near the root of the U. S. form as shown in Fig. 5. The stress developed in the thread would be the same in both types. The required modification is given in Table 2.

Despite the failure of Congress to pass the Urgency Deficiency Bill, the United States Employment Service will continue to carry on the work of finding jobs for the men who have served their country in its hour of need. While the Service has been cut down 80 per cent, the representatives of the Bureau are still retained in the demobilization camps, and through the coöperation of individuals not connected with the Government, it is believed that many of the offices which it has been announced would be closed, will be kept open. Instead of two offices in New York State, there are indications that the number will reach at least twelve, and the Service has also arranged to continue a total of fifty-six offices throughout the country. John B. Densmore, Director-General of the Employment Service, urges that business, labor, welfare and all other interests in every community in which a federal employment office has been abandoned, take over the office and its work, in order to help meet the emergency.

NEWS OF THE ENGINEERING SOCIETIES

Reports of Annual Meetings of Mining and Electrical Engineers and Electric Railway Association —The Aims of an Engineering Society, etc.

Taylor Society to Locate in Engineering Societies' Building

The Taylor Society, which is perpetuating the doctrines of the late Frederick W. Taylor, Past-President Am.Soc.M.E., hopes soon to secure headquarters in the Engineering Societies' Building. Meanwhile the society is being temporarily accommodated in the rooms of our Society.

Rochester Engineering Society

Members of the Rochester Engineering Society, at its monthly meeting in its rooms, No. 131 to No. 135 Sibley Building, March 14, were addressed by LeGrand Brown, who has been in San Francisco for several years practicing as a consulting engineer, on "California's Development of Natural Resources."

Mr. Brown has been intimately connected with electric railway, power, irrigation and water-supply projects, and has also been brought into constant touch with the economic and engineering development of the Pacific Coast.

He described at length the development of California's electric transportation and natural resources. The Los Angeles aqueduct was shown on the screen and explained, as well as the proposed Hetch Hetchy water-supply project for San Francisco.

Mr. Brown is a charter member and past-president of the Rochester Engineering Society. Before he left Rochester he was connected with the street railway, the building of the Hemlock lake conduit by the city, and earlier electric suburban lines.

Material-Handling Machinery Association Formed

The organization has been completed of an association of manufacturers of machinery for handling materials. The suggestion for the organization was made by the Department of Commerce and the U. S. Shipping Board to facilitate the study of freight-handling methods at railroad and ocean terminals. By mobilizing the experience and ability of all manufacturers of handling devices into a single organization, the Government will not only be able to reach this industry in an effective way when it needs coöperation, but the industry itself can more effectively attack the large and difficult problems presented at terminals and ports.

Other lines of activity are to be taken up, however, in relation to the material-handling problems of the various industries. The president of the association is Calvin Tomkins, formerly Commissioner of Docks, New York City. Headquarters will be at 35 West 39th Street, New York, and the active conduct of the association's work will be in the hands of Mr. Zenas W. Carter, the secretary and manager.

American Welding Society to be Organized

The representatives of over 90 societies, institutions and corporations who during the war greatly developed the art of welding, will meet on March 28, 1919, at the Engineering Societies Building, 29 West 39th Street, New York, with a view of forming The American Welding Society. This Society will merge the Welding Committee of the Emergency Fleet Corporation and the National Welding Council, both of which were created during war times by the Council of National Defense.

The discussions, researches, lectures and conferences, as well as the interchange of views with foreign countries which were carried on during the war, aroused in this country a great interest in the use of electric welding and it is expected that the advance in welding thus made will be continued and extended to the entire field of joining metals. The American Welding Society proposes to bring together, in the manner usual for scientific societies, persons from all branches of the industry who may be interested in any of the welding processes, whether it be forge welding, electrical resistance welding, gas welding or thermal welding.

The society will also create and assist in maintaining a bureau of welding, which will be a separate organization designed to take advantage of the principle of coöperation in research and standardization.

As part of its routine the society plans to conduct a research of the methods of welding and to determine, if possible, the conditions under which the best welds may be secured. This involves investigations of the best current to use with various sizes of electrode and different types of work, and a determination of the proper method of procedure in making up both gas and electric-arc welds, coupled with an adequate system of inspecting the work as it progresses. In arc and gas welding the proper angle of bevel and the space to be allowed between plates must be selected and an investigation made of "electrode" wire and of "welding wire."

In gas, spot, or arc welding, methods of assembling large structures to eliminate initial or locked-up stresses due to contraction on cooling, are also to be investigated.

The benefits of standardization are also well recognized by the new society, for they intend to carry on this important work in a way to meet the approval of the American Engineering Standards Committee.

The Aims of an Engineering Society

At the annual meeting of the Engineers' Society of North-Western Pennsylvania, held at Erie, in January, the newly elected president, Mr. Armin Schotte, C.E., outlined what he believed should be the aims of the society and its part in public affairs. He said:

During the pioneer days, and up to near the close of the last century, engineers organized themselves into societies, which became national in scope. The purpose of these societies was to enlarge the sum total of technical knowledge by the interchange of information among themselves. Such work was of the utmost importance at that time, and was a material factor in adding to the store of available data.

During the last twenty years, however, conditions have changed, and in many cases successful steps have been taken to remedy them. What has proved antiquated and practically useless in the case of the national societies would be still more so in smaller local organizations such as ours. So, since we can hope, as a body, to add but little to the sum total of new engineering knowledge, and if we tried, would probably be wasting time which might be put to a better purpose, why undertake it?

The question naturally arises, What are the aims which justify us in maintaining and fostering our society? Without concerted effort in any way, but rather sporadically, new methods have been developed in the conduct of local engineering associations, and I am happy to say that we have, unconsciously perhaps, generally pursued a policy in harmony with them, to which I believe this society owes a large part of its successful growth.

The ultra-serious consideration of any technical subject has either very little or no place in this new policy. The programs are made up and the subjects treated in a manner to interest not merely specialists, but all classes of technically trained men; and in a large number of cases even laymen. The meetings thus assume an attractiveness which will assemble a maximum number of engineers of various lines, and also laymen, thus aiding to establish proper and pleasant relations among the engineers themselves, and to bring the profession before the public in an effective manner. By continuing this policy we shall soon be able to extend our work and help ourselves and every other engineer to conserve and maintain all of the rights and privileges, both mental and legal, to which the individual and the profession at large are justly entitled; to render to the public such service as we are

qualified to perform; to create the proper appreciation of the function of the engineer generally, be he employee or maintaining an office of his own, and to compel a recognition for ourselves as a necessary factor in the civic and political growth of our community and the nation.

The retiring president, Mr. R. C. Stevens, who was unable to attend the meeting, sent a communication in which he referred to The American Society of Mechanical Engineers as follows:

Another very interesting sign of the times is the increased interest in the human element of engineering. Witness the December meeting of the A. S. M. E., when they held an all-day session on Engineering of Man Power. We have long had papers and discussions on wage systems; but now we have increased interest in welfare, safety and the personal relations of employer and employee. Success in engineering is not alone the mastery of mechanisms and securing output from machines, but also, and more important, the organization and training of men and the guiding of industry to augment the usefulness and happiness of mankind.

American Electric Railway Association

THE meeting of the American Electric Railway Association held in the Engineering Societies Building on March 14 was well attended by electric executives from all over the United States and Canada. The most important and valuable discussion during the convention centered around the report of the Association's Committee on Readjustment. The chairman of this committee, Mr. P. H. Gadsden, president of the Charleston Consolidated Railway & Light Co., submitted a preliminary report embracing the fundamentals of a plan for readjusting the relations between the communities and the electric-railway companies.

The committee reported that the present state of the industry was largely the result of a fixed rate of fare made with little consideration of the adjustment of price to meet cost. It was therefore necessary, if the railways are to survive and continue service, that some system of flexible fares, to increase and decrease as the cost of furnishing the service increases or decreases, be established.

Following the report of the committee there was a discussion of the so-called "service at cost" franchises such as are now in effect in Cleveland, Cincinnati, and Montreal. In these cities the fares are automatically regulated, the company receiving a stipulated return upon its money and the city specifying the service which the company shall furnish for the public.

A. Merritt Taylor, a former manager of the Division of Passenger Transportation for the United States Shipping Board and president of the Philadelphia and Westchester Traction Company, also spoke on Modern Regulatory Plans and Theories.

In the afternoon Francis H. Sisson, vice-president of the Guaranty Trust Company of New York, read a paper on Electric Railways and the Investor; and Hon. Charles E. Elmquist and Hon. William D. B. Ainey spoke on Electric Railways and Regulatory Commissions.

In the evening a dinner was held at the Waldorf-Astoria at which Hon. Francis Burton Harrison, Governor-General of the Philippines; Hon. Lindley M. Garrison, Receiver of the Brooklyn Rapid Transit Company; and B. A. Hegeman, Jr., spoke. John H. Pardee, president of the association, presided.

American Institute of Electrical Engineers

THE Seventh Annual Midwinter Convention of the American Institute of Electrical Engineers was held at New York on February 19 to 21. The opening session was a joint meeting with the American Institute of Mining Engineers, at which matters pertaining to the Engineering Council were considered. Mr. Leighton, representative of the Council at Washington, outlined the plans of the organization, which include a movement toward creation of a department of public works, and a federal engineering department under which all engineering activities of the Government shall be correlated and presided over by a member of the engineering profession.

C. A. Adams, president of the A. I. E. E., gave a brief account of the work of the welding committee, after which the technical papers for the session were presented.

On Wednesday evening Dr. J. A. Brashear delivered a lecture on The New Astronomy to an audience which completely filled the auditorium. The lecture was accompanied by numerous lantern slides showing disturbances on the surface of the sun. These slides had never been shown before. The lecture was followed by an exhibition of moving pictures illustrating the operation of the Burroughs adding machine and the telephone receiver and transmitter.

The technical session on Thursday morning was devoted to a discussion of the various phases of standardization in engineering work. Dr. C. P. Steinmetz presented in abstract his paper on General Equations of the Electric Circuit, and H. S. Osborne discussed the subject of Wave-Shape Standards.

Thursday afternoon was set apart for technical excursions. Inspection trips were made to the Brooklyn Navy Yard and the Bell System Laboratories of the Western Electric Company. Members and guests were transported from the Engineering Societies Building in busses to the foot of 23rd Street, where the Navy Department supplied large sea-going tugs to carry the party to the Navy Yard. The party spent an interesting afternoon inspecting the power plant, shops, dry docks, and various other features of the yard.

The Western Electric Company provided cabs for those who visited their plant. Members and their guests also had the leadership of a guide as they went through the Bell System Laboratories.

The final session was held on Friday and was exclusively devoted to technical papers. Of these the most valuable and interesting was on Radio Telephony, by E. B. Craft and E. H. Colpitts, both of the Western Electric Co. The paper described the development of the art of radio telephony to the accomplishment of transatlantic communication and the use of radio telephony between ships. The production of apparatus for both Army and Navy aircraft was also outlined, the essential features of which were the design of light and compact sets.

Mining Engineers Adopt a New Name

FROM the beginning to the end, the attendance and enthusiasm of the 119th meeting of the American Institute of Mining Engineers, which was held in New York, February 17 to 20, surpassed all expectations. Besides the ten technical sessions, one of which was in conjunction with the American Institute of Electrical Engineers and one a session of the National Research Council, there were two memorial meetings, one for Dr. Rossiter W. Raymond, for twenty-seven years secretary of the Mining Engineers, and one for the members who had died in service. Two joint sessions with the Canadian Mining Institute, and a meeting devoted to pictures of copper mining, milling, and smelting were also held.

One of the most important events in the history of the Institute took place at the annual business meeting on February 18, when the Institute voted to change its name from the American Institute of Mining Engineers to the American Institute of Mining and Metallurgical Engineers.

It is the consensus of opinion that this marks an epoch in the history and usefulness of this Institute, and it is expected that the change will presage a large and healthy growth in metallurgical fields. Many metallurgists who knew nothing about mining were loath to join a society of mining engineers, despite the fact that over 35 per cent of the papers published in its transactions during the past five years dealt with metallurgical subjects. Additional appropriateness in the new name lies in the fact that the American Institute of Metals is now an important part of the larger organization.

The choice of the name has the double advantage, much to be desired, of retaining the word Engineers and maintaining the former initials of the Institute, A. I. M. E.

At this session the announcement was also made of the election of Horace V. Winchell, Minneapolis, as president.

Technical Sessions

The technical sessions covered a wide field of engineering, and in the Engineering Survey Section will be found abstracts

of some of the more important papers which were presented. The sessions were devoted to problems of industrial organization, the Institute of Metals Division, and to petroleum and gas. Among the special features of these sessions were the topical discussions on housing and Americanization. Americanization, too, was the topic for discussion by the Woman's Auxiliary on Wednesday morning.

Canadian Mining Institute Day

On Tuesday, nearly 100 members of the Canadian Mining Institute were present to discuss the possibility of bringing about uniform mining laws for the United States, Canada, and Mexico, to obviate the maintaining of separate legal departments and managerial forces for the several countries; and to avoid the confusion which, it is said, has led to duplication of effort and has sometimes created a barrier to international coöperation.

Four joint discussions formed the program of the sessions with the Canadian Mining Institute. T. W. Gibson, the representative of the Canadian Mining Institute, opened the discussion on the subject of Principles of Mine Taxation, in which the American Institute was represented by Ralph Arnold, of the United States Treasury Department. Later, Alfred G. Heggem, of Tulsa, Okla., cited an instance in which a high rate of taxation decreased the Government's revenue by retarding the transfer of property. The second discussion of the morning was on the subject of Industry, Democracy, and Education. C. V. Corless represented the visitors and President Jennings the A. I. M. E.

In the afternoon, Mr. T. A. Rickard, of San Francisco, Cal., opened the discussion by a paper entitled The English-Speaking People. He was followed by Dr. A. R. Ledoux, of New York, who gave a brief talk on International Coöperation. In it he spoke of the necessity of closer coöperation, also, with Mexico. President Jennings later said that he is planning a trip to Mexico, when he expects to meet with the Local Section in Mexico, and hopes to initiate some discussion of problems that confront the American engineer. The question of a uniform mining law for North America provoked considerable discussion. While most of the talk was confined to the various Canadian laws, the possibilities of uniform laws with Mexico and Central America were also considered.

Wednesday was devoted to the work of the National Research Council, which occupied the entire day and not only the morning as was planned, to the problems of mining, milling, and geology, and to the study of welding problems, jointly with the American Institute of Electrical Engineers. In all cases the discussion was most animated.

Work of Bureau of Standards in 1918

In the recently issued annual report of the Director of the Bureau of Standards, it is stated that during the fiscal year ended June 30, 1918, the Bureau studied many interesting applications of science to warfare, such as methods for locating enemy batteries; development of new materials, appliances, and methods; and other technical researches of military problems.

The regular work of the Bureau, however, yielded interesting and important results. Apart from new researches, a large volume of testing was completed. The construction of the new industrial laboratory, the completion of the metallurgical laboratory, and the building of a number of emergency war laboratories for airplane investigators were events of interest and will be of great value in the development of the several branches of technology within the activities of the Bureau.

Congress has authorized the establishment of a Government coal yard, or yards, in the District of Columbia, from which all federal buildings will be supplied; this yard will be placed under the supervision of the Bureau.

Apart from confidential reports, the Bureau published during the year about 50 new publications, including scientific and technologic papers, circulars, and bulletins.

Altogether the report of the Director shows an extremely wide range of industrial-research problems in progress, which will be of material aid in readjusting industry to peace conditions.

ROLL OF HONOR

DIED IN THE SERVICE

Hoskins, Stephen Paul, Lieutenant, Co. L, 319th Infantry, American Expeditionary Forces, France.

Lynch, Thomas M., Major, General Supplies Division, Quartermaster Corps, U. S. Army.

Seed, Chas. R., Lieutenant, U. S. Naval Reserve Force.

The following list of names of members in the Service has been compiled during the last two months. It contains, in many cases, names of members who are now discharged from the Service but of whose connection with Army or Navy there has been no previous mention.

Armacost, W. H., Second Lieutenant, Refrigerating Plant Co. 501, American Expeditionary Forces, France.
Auerswald, H. R., First Lieutenant, Chemical Warfare Service, U. S. Army.
Baldwin, C. M., Lieutenant, U. S. Naval Reserve Force.
Barry, Ralph E., Lieutenant, U. S. Naval Reserve Force; Line detailed to Construction, Philadelphia Navy Yard.
Blank, B., Private, First Class, Co. D, 309th Infantry, 78th Division, U. S. Army.
Bunker, A. H., Lieutenant (junior grade), Aviation, U. S. Navy.
Buzby, Paul M., First Lieutenant, Ordnance Department, U. S. Army.
Carlson, C. A., First Class Private, 20th Company, Artillery, U. S. Army.
Cartwell, N. M., Chief Machinist's Mate, U. S. Naval Reserve Force, U. S. Navy Steam Engineering School.
Danks, R. L., Chief Petty Officer, Machinist Division, U. S. Naval Reserve Force.
Flickinger, H. W., Captain, Division of Military Aeronautics, Air Service, U. S. Army.
Goedkoop, Walter C., Corporal, Co. I, 2d Pioneers' Infantry, American Expeditionary Forces, France.
Goezenberger, R. L., Captain, Ordnance Department, American Expeditionary Forces, France.
Goodwin, Guy L., Second Lieutenant, Coast Artillery Reserve Corps, U. S. Army.
Graesser, C. F., Electrician, First Class, Communication Service, U. S. Navy.
Haasis, P. W., Flying Cadet, Squadron 65, S. M. A., Aviation Barracks, Berkeley, Cal.
Harris, W. A., First Lieutenant, Coast Artillery Reserve Corps, U. S. Army.
Hess, A. McD., Ensign, U. S. Navy.
Higley, F. R., Lieutenant, The Infantry School of Arms, Camp Banning, Columbus, Ga.
Igleheart, G. P., Ensign, U. S. Navy.
Johnson, H. S., Captain, 26th Artillery, Coast Artillery Corps, U. S. Army.
Kuttner, J., Warrant Machinist, U. S. Naval Reserve Force.
Macy, R. G., Lieutenant, Ordnance Department, U. S. Army; assigned to Sandy Hook Proving Ground, Sandy Hook, N. J.
Masser, Harry L., Ensign, U. S. Navy.
Nelson, J. E., Ensign, U. S. Navy.
Purinton, J. W., First Lieutenant, Ordnance Department, U. S. Army.
Rahner, Maxwell L., Corporal, Meteorological Section, American Expeditionary Forces, France.
Ralph, J. J., Lieutenant, Purchase, Storage and Traffic Division, General Staff, U. S. Army.
Ranton, J. L., Captain, Co. G, 1st Hawaiian Infantry, U. S. Army; stationed at Schofield Barracks, Hawaiian Territory.
Root, F. J., Major, Inspection Division, Ordnance Department, U. S. Army.
Smith, P. M., Second Lieutenant, 1st Co., Rep. Dep. Battalion, Signal Corps, American Expeditionary Forces, France.
Snyder, C. L., Second Lieutenant, Nitrate Division, Ordnance Department, U. S. Army.
Sparks, H. C., D.S.O., M.C., Colonel, 3d Army Labour Commandant, British Expeditionary Force, France.
Thee, W. C., Captain, Coast Artillery Corps, Amcrican Expeditionary Forces, France.
Uehling, E., Second Lieutenant, 6th Anti-Aircraft Machine Gun Battalion, U. S. Army.
Wilson, Leroy A., First Lieutenant, Air Service, Aeronautics, U. S. Army.
Windle, A. E., Second Lieutenant, Air Service, American Expeditionary Forces, France.
Woodbury, J. G., Major, Production Division, Ordnance Department, U. S. Army.
Woolner, S. A., Second Lieutenant, Air Service, Aircraft Production, U. S. Army.

NECROLOGY

J. SELLERS BANCROFT

J. Sellers Bancroft, a member of the Society since 1880, manager from 1909 to 1911, and vice-president from 1915 to 1917, died at his home in Philadelphia on January 29 after an illness of several months.

Mr. Bancroft was born in Providence, R. I., on September 12, 1843. His father, Edward Bancroft, a distinguished engineer, who made many inventions of machine tools and shafting appliances, founded the firm of Bancroft and Sellers, now Wm. Sellers & Co., Inc., Philadelphia. As a sidelight on the growth of the machine-tool industry in this country, it is interesting to note that Edward Bancroft built the first metal planer in the United States, the bed and table being chipped and filed by hand.

J. Sellers Bancroft was educated in Philadelphia, being graduated from the high school of that city in 1861. In February of that year he entered the employ of Wm. Sellers & Co., being apprenticed to his uncle, Wm. Sellers. In 1863, at the age of twenty, he was made gang foreman, and in 1866 general foreman. He was admitted to the firm in 1873, and when the business was incorporated in 1887 he was made general manager.

While with the Sellers Co. he was granted many patents on machine tools, injectors, shafting appliances, power cranes and their interlocking electrical devices.

For forty-one years he remained with this company, leaving in 1902 at the age of fifty-nine to become general manager and mechanical engineer of the Lanston Monotype Machine Co., Philadelphia. In the following sixteen years of his life he did his greatest engineering work; the perfection of the monotype and the special machines for making the molds and matrices used with it for casting and composing type in automatically justified lines. The organization of the monotype factory exemplifies his work as an executive and a leader of men.

A keen lover of books, it was a great joy to him that his work did much to raise the quality and reduce the cost of printing not only in the United States, but also throughout the world.

At the time of his death he was vice-president and treasurer of the Monotype Co., as well as its general manager and mechanical engineer.

More than 100 patents testify to the scope of Mr. Bancroft's engineering work and the range of his creative ability. To those who worked with him on the solution of any of the many problems that engaged his attention, his thoroughness, the result of his never-failing perseverance and patience will be an ever-inspiring memory.

J. Sellers Bancroft

GEORGE URQUHART BORDE

George U. Borde, consulting engineer, died in New Orleans, La., on December 17, 1918. He was born in January 1871 in New Orleans and was graduated from Tulane University in 1888. Mr. Borde was formerly district engineer for the southern district of the Edison General Electric Co. After a short period in the contracting business in Memphis, he opened consulting offices in New Orleans, which he still maintained at the time of his death. He became a member of the Society in 1908.

Mr. Borde, at the time of his death, was one of the most prominent consulting engineers in the City of New Orleans. He was retained as consulting engineer by the Great Southern Lumber Co. and also by the United States Industrial Alcohol Co. In connection with his work for the latter, his investigations in regard to the process of the manufacture of ethol alcohol from wood waste was possibly his most important work.

GEORGE K. GARVIN

George K. Garvin, president of the Garvin Machine Co., New York, died at his home in Garden City, Long Island, on February 20, 1919. Mr. Garvin was born on May 2, 1859, in Hartford, Conn. He was educated in the public schools of New York and Jersey City, later attending Hasbrouck Institute. At the age of sixteen he entered his father's business, then known as Smith & Garvin, and upon his father's death became president of the concern. He became a member of the Society in 1909.

WALTER V. TURNER

Walter V. Turner, manager of engineering of the Westinghouse Air Brake Co., died at the Columbia Hospital, Wilkinsburg, Pa., January 9. Mr. Turner was born in Epping Forest, Essex, England, in 1866, and was educated in the Textile Technical School of Yorkshire. He came to this country in 1888 and settled in the West, where he became the manager of a sheep and cattle company. For several years he was general air-brake inspector for the Atchison, Topeka and Santa Fé Railroad. In 1903 he became connected with the Westinghouse Air Brake Co. as engineer, remaining with that company and associated interests until his death.

Mr. Turner was an inventor of international prominence, patenting more than 400 devices in use on railroads and in industrial plants. For his achievements as an inventor in the development of the air brake, he was awarded the Elliott Cresson and the Edward Longstreth medals by The Franklin Institute of Philadelphia. In May 1918 the University of Pittsburgh conferred the degree of Doctor of Engineering upon him. He became a member of the Society in 1913.

CHARLES EDWARD JOHNSON

Charles E. Johnson, chief engineer of the Diamond Gasoline Co., Kansas City, Mo., died on January 5, 1919. He was born in December 1883 in East Atchison, Mo., and was a 1910 graduate of the University of Kansas. Mr. Johnson was formerly connected with the Santa Fe Railway Co. as draftsman and with the Lawrence Paper Mill, Lawrence, Kan., as chief engineer. He had also held the position of instructor in mechanical drawing in the high schools of Kansas City and Ottawa, Kan. He became an associate-member of the Society in 1918.

THOMAS M. LYNCH

Thomas M. Lynch, Major, General Supplies Division, Quartermaster Corps, U. S. Army, died on December 18, 1918. He was born on July 2, 1882, in Worcester, Mass., and attended the Worcester Polytechnic Institute. Major Lynch had formerly been connected with the Buena Vista Extract Co., as superintendent, and was also for two years staff member of the J. J. Lynch Co., New York. At the time of his death, Major Lynch was Chief of the Administrative Branch of the General Supplies Division, Quartermaster Corps, having been placed in charge of that department at the time of its creation. He organized this whole division and received his appointment as Major in recognition of his merit and the efficient results he had secured. Major Lynch became an associate-member of the Society in 1914.

HENRY GEORGE PULSCHEN

Henry G. Pulschen, of the inspection department of the J. G. White Engineering Corporation, New York, died on December 24, 1918. Mr. Pulschen was born in February 1891 in New York City and was a graduate of Cooper Union and of Pratt Institute. He had formerly been associated with the H. R. Worthington Co. as detailer on power-plant machinery and as designer and checker with the Alberger Pump & Condenser Co. Mr. Pulschen became a junior member of the Society in 1918.

HENRI LEAUTE

[News of the death of Henri Léauté, a distinguished Honorary Member of this Society, was received some time ago, but owing to war conditions it has not been possible to secure data for a suitable memorial notice until quite recently.—Editor.]

Henri Léauté, the great French engineer and mathematician, was born in 1847. In 1866, at the age of 19, he had the unique distinction of being accepted at the head of a long list of competitors for entrance into two of the best technical schools in France, the Ecole Polytechnique and Ecole Normale. He entered the latter and was graduated in 1869 with the degree of engineer.

The war of 1870 naturally interrupted his professional career, but, released from military service in 1871, the young man at once engaged in three lines of work requiring very dissimilar characteristics of mind

Henry Léauté

those of medicine, mathematics and mechanics, and rapidly established an important position for himself in each of these branches of science.

The first paper published by Léauté dealt with partial derivative equations of the first order. Of much greater importance was the second paper, dealing with friction in bearings. Other of his works covered the subjects of general kinematics, strength of materials, dynamics and theory of machines. In all of this work he made extensive use of higher mathematical methods in the solution of mechanical problems. It is significant, however, that in all his work he carefully avoided the use of mathematics for its own sake and never lost sight of the practical applications of his investigations.

In kinematics, Léauté introduced a new conception, namely, the order of proximity of two arcs of neighboring curves. Because of this concept he was enabled to formulate precise mathematical rules to take the place of former approximations, and these he applied in the design of gears and in the improvement of Watt's parallelogram and the Farcot governor.

In the field of the strength of materials, Léauté developed important data in relation to the elastic deformation of circular members and the distribution of stresses in cylindrical bands, especially in band brakes. Of the greatest importance, however, were his master papers dealing with dynamics and the theory of machines. His treatise on Telodynamic Transmission has become a classic. The transmission of power at a distance by means of cables was fully solved by him, both from the theoretical and practical points of view. The great importance of this work has failed to be realized only because the introduction of electric transmission has materially reduced the field of application of cable transmission.

The governing of engines formed the subject of several papers of great importance. Starting with the study of flyball governor, he gradually passed to that of oscillations having long periods and investigated the whole field, applying new and ingenious mathematical methods.

In addition to his scientific work, Léauté took a prominent part in national educational activties, and also in business, where he held important positions, such as that of president of the French Telephone Company and also of the Paris Electric Distribution Company.

In 1891 he was elected honorary member of The American Society of Mechanical Engineers. In 1915, notwithstanding a malignant disease which for years had sapped his strength, he took an active part in the management of war industries, on the running of which depended the defense of the country at that time. It is no exaggeration to say that this patriotic activity was the prime cause of his death.

ALFRED H. RAYNAL

Alfred H. Raynal, member of the Society since 1884 and manager from 1889 to 1902, died at his home in Washington, D. C., on March 1. Mr. Raynal was born on August 5, 1848, in Hamburg, Germany, serving his apprenticeship as mechanic and draftsman in a marine-engineering establishment there. In May 1862 he came to the United States and worked as a machinist and draftsman for private concerns in New York. In 1863 he was engaged by the Navy Department as draftsman on the design of twenty light-draft monitors. In 1864 he made the drawings for and superintended the construction of the monitor *Squando* at the works of McKay Aldus at East Boston, Mass.

He next entered the employ of the Babcock & Wilcox Co., Providence, R. I., working out details of their engine and boiler which latter is now used so extensively in the U. S. Navy. In 1870 Mr. Raynal became superintendent of the works of Poole & Hunt, Baltimore, who were building engines and boilers under the Babcock & Wilcox patents. From 1880 to 1884 he was superintendent of the Wheelock Engine Works, Worcester, Mass. He was next connected with the DeLamater Iron Works, New York, as superintendent, where he did considerable work for Capt. John Ericsson, building his submarine gun, high-expansion engine, sun motor, etc. In recognition of his services to him, Captain Ericsson presented Mr. Raynal with a rare and valuable book on his inventions. This book was presented to the Society by Mr. Raynal for record.

From 1890 to 1897 he successively held the following positions: Superintendent of the Richmond Locomotive Works, building the machinery of the U. S. battleship *Texas;* superintendent of Samuel Moore & Son's Shipyard, Elizabeth, N. J., building the revenue steamer *Maple* and the practice cruiser *Bancroft;* superintendent of the Corliss Engine Co., Providence, R. I.; superintendent of the Walker Co., Cleveland, Ohio. In 1897 Mr. Raynal studied patent law, working in an attorney's office in Cleveland.

In 1898, during the Spanish War, at the personal request of Admiral Melville, he entered the Navy Department as draftsman to design engines for the first sixteen torpedo-boat destroyers, as his experience in building successfully the spider-frame high-speed engines of the *Bancroft* had been unusually valuable.

From that time Mr. Raynal's work was in the Navy Department where he was of signal service in the Bureau of Steam Engineering. Mr. Raynal acted as expert engineer in the courts in suits resulting from explosions of boilers, bursting of flywheels, etc., and in admiralty cases.

He was a member of the American Society of Naval Engineers and Marine Architects, the American Society of Naval Engineers, the Washington Society of Engineers, and the American Society of Marine Draftsmen.

CHARLES R. SEED

Charles R. Seed, for the last seven years chief engineer of the Worcester Electric Light Co. and recently lieutenant in the United States Naval Reserve Force, died in Worcester on October 8, 1918, of pneumonia. Mr. Seed was born in April 1876 in Lawrence, Mass., and was educated in the schools of that city, later receiving training aboard the Massachusetts Nautical Schoolship *Enterprise*, for seven years serving as engineer on runs between Europe and America. When the United States declared war against Germany he offered his services, was commissioned ensign and assigned to overseas patrol duty in the war zone, later being promoted to lieutenant. He had formerly served as chief engineer with the Blackstone Manufacturing Co., Blackstone, Mass., and as superintendent of power with the Rockingham County Light & Power Co., Portsmouth, N. H. Mr. Seed became an associate-member of the Society in 1914.

ROY BROOKS SMITH

Roy Brooks Smith, assistant electrical engineer Pennsylvania Lines West, died on October 19, 1918. He was born in Uhrichsville, Ohio, in March, 1882. In 1904 he received his M. E. degree from Ohio State University, serving his apprenticeship during his vacations with the Pennsylvania Lines West. Upon graduation he became connected with the same company as assistant engine-house foreman. He was rapidly promoted to more responsible positions, and just previous to his death was made assistant electrical engineer. He became a junior member of the Society in 1905 and was promoted to full membership in 1912.

HENRY DREW EGBERT

It is with deep regret that we announce the death of the Secretary of our New York Section Committee, Henry Drew Egbert. Mr. Egbert died on Sunday, March 23, in his 33d year. A more extended notice will appear in an early issue of Mechanical Engineering.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by March 15 in order to appear in the April issue.

CHANGES OF POSITION

G. H. Cooper, formerly secretary and treasurer of the Electric Company, Hartford, Conn., has become identified with the H. T. Paiste Company, Philadelphia, Pa., in the capacity of mechanical superintendent.

Chester H. Mannion, until recently chief engineer, Kerr Mills, American Thread Company, Fall River, Mass., has entered the employ of the Nashua Manufacturing Company, Nashua, N. H., in charge of their steam plant.

Robert D. Koplin has left the employ of the Air Nitrates Corporation Agents of the U. S. Ordnance Department, to accept a position in the office of the chief engineer of construction of the Weirton Steel Company, Weirton, W. Va.

W. Harwell Allen has assumed the duties of secretary and assistant manager of the Memphis Heating Company, Memphis, Tenn. He was until recently associated with the J. G. White Engineering Corporation, Sheffield, Ala.

John Fisher, formerly chief engineer, Hartford district, of The Connecticut Company, Hartford, Conn., has accepted the position of chief engineer of the Quincy Point Power Station of the Bay State Street Railway Company, Quincy, Mass.

L. F. Merritt has severed his connections with the Bureau of Aircraft Production and has become associated with Joseph N. Smith and Company, of Detroit, Mich., as mechanical engineer.

E. T. Koskinen, formerly affiliated with the Nordberg Manufacturing Company, Milwaukee, Wis., as draftsman, has become connected with the machinery division of the Newport News Shipbuilding and Dry Dock Company, Newport News, Va.

Robert W. Schuette, recently mechanical engineer with the Mesta Machine Company, Pittsburgh, Pa., has become affiliated with the Harrisburg Pipe and Pipe Bending Company, Harrisburg, Pa.

William E. A. Walther has become associated with the United Glass Bottle Manufacturers, of London, England. He was formerly in the service of the Illinois Glass Company, Alton, Ill., in the capacity of mechanical engineer.

Norman G. Hardy has assumed the position of chief mechanical and electrical engineer for the Arizona Copper Company Ltd., Clifton, Ariz. He was formerly associated with the Old Hickory Powder Plant, Jacksonville, Tenn.

Mather W. Sherwood has left the employ of the Burke Electric Company and has entered the service of the Ball Engine Company, of Erie, Pa.

Louis Mardaga has assumed the duties of sales engineer for the Mickle Milnor Engineering Company, Philadelphia. He was until recently assistant naval inspector of Ordnance, Alloy Steel Forging Plant, Carnegie, Pa.

Ralph C. Chesnutt, formerly with the Willys-Overland Company, Toledo, Ohio, is now assistant chief engineer for the North American Motors Company, Pottstown, Pa.

C. L. Horne, formerly mechanical engineer with the Underfeed Stoker Company, Chicago, Ill., has become associated with The Texas Company, Roanoke, Va., in the capacity of lubricating engineer.

George A. Hickerson has resigned his position as a mechanical appraiser with Ford, Bacon and Davis, New York, to accept a position as chief engineer with the Rhodia Chemical Company, New Brunswick, N. J.

Howard M. Groff has assumed the duties of chief engineer of factories for Robert H. Ingersoll and Brother, of New York. He was recently affiliated with the Frankford Arsenal, Philadelphia, Pa., as gage expert.

Charles E. Beck, formerly sales engineer with Baker-Dunbar-Allen Company, Cleveland, Ohio, has accepted a similar position with the Busch-Sulzer Bros.-Diesel Engine Company, St. Louis, Mo.

J. A. Polson, professor of mechanical engineering at the Michigan Agricultural College, East Lansing, Mich., has resigned to accept a position of factory manager with the Milwaukee Stamping Company, of Milwaukee, Wis.

ANNOUNCEMENTS

Ray B. Whitman, formerly with the Emergency Fleet Corporation at Cleveland, is now inspecting the construction and machinery installation of steel river paddle steamers and barges for the Dravo Contracting Company of Pittsburgh, Pa.

V. L. Sanderson has had supervision of the Philadelphia district of the Terry Steam Turbine Company since the death of Charles E. Hague in April 1917.

E. D. Latter is a member of the firm of Harris, Latter and Company, New York, which has recently been formed to conduct business as constructive accountants and auditors.

John E. Muhlfeld has assumed the presidency of the Pulverized Fuel Equipment Corporation, which has recently been organized for the purpose of taking over the business of the Locomotive Pulverized Fuel Company. Mr. H. F. Ball is Vice-President Executive, and V. Z. Caracristi is Vice-President in charge of engineering, of the company.

Frederick A. Waldron, consulting engineer, announces that in addition to his consulting practice he has established a bureau for audit and inspection of organizations and factory methods. The object of this bureau is to provide periodical reports for boards of directors or the officials of corporations as to the efficiency of the operating and producing factors of their organizations. The services of this Bureau will also be available for consultation relative to the formation of new organizations and industrial enterprises.

Prof. W. H. Kenerson, of Brown University, is now in France organizing instruction in mechanical engineering in the Army of Occupation, and is a member of the committee secured by the Y. M. C. A. to advise the Army authorities there in these matters.

R. W. Baily has accepted the position of assistant general manager of the Jacksonville Dry Dock and Repair Company, Jacksonville, Fla.

Lieut. A. G. Kessler, U. S. N. R. F., who for six months past has been in charge of the Gun Division of the Bureau of Ordnance, Navy Department, has been released from active duty in the Naval Service and has become vice-president of the General Ordnance Company, Derby, Conn., and of the National Tractor Company, Cedar Rapids, Ia., in charge of purchasing and production at both plants. Mr. Kessler was formerly general manager of the Lakeside Forge Company, Erie, Pa.

Calvin L. Halladay has become affiliated with the Jackson Motor and Manufacturing Company, Jackson, Mich.

Lieut. R. K. MacMaster and Lieut. George S. Van Gelder, of the Ordnance Department Claims Board, will resume their work in the field of production and cost accounting under the firm name of MacVan Engineering Company, with offices at 50 East 42d Street, New York.

Charles Piez, director general of the Emergency Fleet Corporation, will resign his position, effective May 1, to return to Chicago to resume the presidency of the Link-Belt Company.

T. E. Butterfield, associate professor of mechanical engineering at Lehigh University, is back after service on the teaching staff of the Post Artillery School at Fort Monroe, Va., where he held the rank of Major.

Huntly H. Gilbert, who left the service of the Pressed Steel Car Company and the Western Steel Car and Foundry Company at the beginning of the war to enter the Army as captain in the Ordnance Department at Washington, and later was commissioned major and transferred to the Rock Island Arsenal, has reëntered the service of the above-named companies as assistant manager of sales of the western district, with headquarters in Chicago, Ill.

William G. R. Braemer has resigned as president of the Braemer Air Conditioning Corporation, Philadelphia, Pa., to open a consulting engineering office in the Stephen Girard Building, Philadelphia. He will specialize in air conditioning and drying and will also act as consulting engineer for the above company.

Lieutenant William P. Hayes, U. S. N. R. F., at present commanding one of the U. S. men-of-war on the China Station, has been promoted to the rank of Lieutenant Commander.

William F. Franket has become connected with the Wood-Mosaic Company, Inc., New Albany, Ind., manufacturers of parquetry, hardwood flooring, veneers and lumber, as manager of the timber department.

APPOINTMENTS

Chester W. Wilson, formerly engineer of the Garfield Smelting Company, has been transferred to El Paso, Tex., and appointed chief engineer of the Mexican Department of the American Smelting and Refining Company.

LIBRARY NOTES AND BOOK REVIEWS

Graphical and Mechanical Computation. By Joseph Lipka, Ph.D. John Wiley & Sons, Inc., New York, 1918. Cloth, 6 x 9 in., 264 pp., 205 figures, 2 folding charts, $4.

This book presents a systematic development of the construction of alignment charts, the value of which in facilitating computation is very generally recognized by engineers. The mathematical treatment employed is simple and the methods are abundantly illustrated by charts for many important engineering formulæ.

Many engineering and scientific formulæ are empirical, and the value of many investigations is much enhanced by the discovery of the laws connecting the results obtained. One chapter of the book deals with the fitting of equations to experimental data, and another considers the case where the data involved are periodic, as in alternating currents, sound waves, etc., and gives numerical, graphical and mechanical methods for determining the constants of the equation. When empirical formulæ cannot be fitted to the data available, the latter may still be efficiently handled for purposes of further computation by the methods for interpolation, differentiation and integration developed in the closing chapters.

The book embodies a course that has been given by the author for a number of years at the Massachusetts Institute of Technology.

The Elements of Wooden Ship Construction. By W. H. Curtis. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 223 pp., 199 illus., $2.50.

A revised and enlarged edition of a course prepared for the education and training section of the Emergency Fleet Corporation. It is intended for the use of carpenters and others, who, though skilled in their work, lack the detailed knowledge of shipbuilding necessary for efficiency.

Fighting the Boche Underground. By H. D. Trounce. Charles Scribner's Sons, New York, 1918. One-quarter cloth, 5 x 8 in., 234 pp., 7 pl., 1 por., 1 diag., $1.50.

Captain Trounce, an American mining engineer, enlisted in the Royal Engineers in 1915, and transferred to the Engineers' Reserve Corps of the American Army in 1917. His book is a description of the underground fighting in which he participated in Flanders, at Arras, Vimy Ridge and elsewhere.

Industry and Humanity. A Study in the Principles Underlying Industrial Reconstruction. By W. L. Mackenzie King. Houghton Mifflin Co., Boston and New York, 1918. Cloth, 6 x 8 in., 567 pp., 10 charts, $3.

This volume by the former Minister of Labor of Canada is a statement of the underlying principles which are finding expression in the organization of industrial society and which should obtain in all efforts at reconstruction. The book is based on the author's twenty years of personal contact with labor problems, supplemented by a study of the literature on the subject.

Instincts in Industry. A Study of Working-Class Psychology. By Ordway Tead. Houghton Mifflin Co., Boston and New York, 1918. Cloth, 5 x 8 in., 222 pp., $1.40.

With the idea of contributing to a better understanding of people in their capacity as manual workers, Mr. Tead has analyzed in turn the ten basic instincts on which our life and conduct rest, has shown how each affects the worker's relation to his job, and how each must be studied and used in the task of attaining sound relations between the employer and the employed.

The Instructor, the Man and the Job. A Handbook for Instructors of Industrial and Vocational Subjects. By Charles R. Allen. J. B. Lippincott Co., Philadelphia (copyright 1919). Cloth, 5 x 8 in., 373 pp., $1.50.

The author, who has been agent for industrial training for the Massachusetts Board of Education and superintendent of instructor training for the Emergency Fleet Corporation, gives the result of his experience in this volume, which is intended as a handbook for instructors in industrial plants and as instruction notes in training courses for instructors.

Johnson's Materials of Construction. Rewritten by M. O. Withey and James Aston. Edited by F. E. Turneaure. Fifth edition. John Wiley & Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 840 pp., illus., 1 pl., 1 por., tables, $6.

As the progress of the last twenty years in the knowledge of the properties of materials made Professor Johnson's book an inadequate account of the subject, it has been rewritten under the editorship of his successor at the University of Wisconsin.

The authors have aimed to retain the broad scope of the original work as a statement of the essential information concerning the sources, manufacture or fabrication of the principal materials, their important mechanical and physical properties and the influence of various factors upon them, the causes of defects and variations, the methods of testing and their general uses. The arrangement of the book is new and some changes have been made in its scope. Obsolete matter has been eliminated and modern data substituted. The volume is intended to serve both as a textbook and as a work of reference.

1919 Record of American and Foreign Shipping, New York. Published by the American Bureau of Shipping, "American Lloyds." New York, 1919. Morocco, 10 x 10 in., 1056 pp.

The 1919 Record presents no change in form from previous years. It provides a record of American and foreign vessels, classified according to the rules of the Bureau, and is endorsed by the Navy Department and the boards of marine underwriters of New York, Boston and San Francisco. In addition to the list of vessels, there are lists of owners, marine underwriters' representatives, surveyors, machinery constructors, dry docks, marine railways, and ship builders. An index of changed names is also included.

Our National Forests. A Short Popular Account of the Work of the United States Forest Service on the National Forests. By Richard H. Douai Boerker. The Macmillan Co., New York, 1919. Cloth, 5 x 8 in., 238 pp., 80 illus., $2.50.

The author presents a well-illustrated account of our national forest problem and of the work of the Forest Service. Written in popular form and based largely upon his personal experience and observation.

Petroleum Refined. By Andrew Campbell, with a foreword by Sir Boverton Redwood. Charles Griffin & Co., Ltd., London, 1918. Cloth, 6 x 9 in., 277 pp., 138 illus., 29 folding pl., 3 diag., 11 tables, $8.50.

This volume describes the ordinary methods used to prepare marketable products from petroleum, except "cracking" methods. The work is based on extended practical experience, is well supplied with illustrations and drawings and includes a bibliography.

Physics for Technical Students. Sound, Light, Electricity and Magnetism. By William Ballantyne Anderson. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 794 pp., 373 illus., $3.

This book completes the author's textbook of physics, the first part of which has been published previously under the title Mechanics and Sound. The writer has aimed to produce a college text especially suitable for students of agriculture and engineering, in which particular attention is directed to practical applications of the subject.

Practical Ship Production. By A. W. Carmichael. First edition. McGraw-Hill Book Co., Inc., New York, 1919. Cloth, 6 x 9 in., 252 pp., 101 illus., $3.

The purpose of this book is to serve as an introduction to the subject by presenting the most important general principles of ship design and describing the various processes of shipbuilding. The treatment is practical rather than theoretical and matters of construction are more fully considered than problems of design.

The Rudder Directory. A Trade List of Shipbuilding and Marine Industries. Compiled and issued by the Rudder Publishing Co., New York, 1919. Cloth, 6 x 9 in., 332 pp., 1 pl., $5.

Included in this directory are lists of the steel, wood, composite and concrete shipyards, with the names of their officers, ship and engine repair plants, dry docks and marine railways, owners and operating companies, marine insurance companies, boat builders, engine builders, ship chandlers and manufacturers of equipment, parts, etc. A supplement, revised to February 6, 1919, brings the data concerning the U. S. Shipping Board and the Emergency Fleet Corporation up to date.

Thomas' Register of American Manufacturers and First Hands in all Lines. Thomas Publishing Co., New York (copyright 1919). Cloth, 10 x 12 in., 4200 pp., $15.

The tenth edition of this well-known trade directory is dated "October" as usual, although corrections were made up to December 20. The directory is divided into various lists, the chief one being a classified list of manufacturers in all lines, sub-classed geographically and provided with an extensive index to the classification. Other lists are of representative banks, boards of trade, chambers of commerce, etc., trade papers, leading trade names and an alphabetical list of manufacturers. The volume contains 4200 pages of information, conveniently arranged for quick consultation.

The Theory of Electricity. By G. H. Livens. The University Press, Cambridge, England, 1918. Cloth, 11 x 7 in., 717 pp. $8.25. (Gift of G. P. Putnam's Sons.)

Dissatisfaction with the treatment of this subject in standard textbooks, which the author believes to be incomplete, often unconvincing and sometimes erroneous, leads him to offer this work as a general textbook on the mathematical aspects of modern electrical theory in which an attempt is made to present the complete subject in a consistent form. Although his exposition is essentially a mathematical one, much of the purely analytical mathematics usually associated with the subject has been omitted. Particular attention has, however, been given to the rigorous formulation of underlying physical principles and to their translation into a mathematical theory. The dynamical aspects of the subject have been specially emphasized throughout.

Classroom Lecture Notes. Automotive Starting, Lighting and Ignition. By R. C. Fryer. Second Edition. John Wiley and Sons, Inc., New York, 1918. Cloth, 8 x 5 in., 210 pp., diag. $1.25.

The author provides a general, concise series of notes, including the essential knowledge needed by the student, but requiring enlargement by the instructor. Eighty-eight pages of wiring diagrams are given.

Practical Oil Geology. The Application of Geology to Oil-Field Problems. By Dorsey Hager. Third edition. McGraw-Hill Book Co., Inc., New York. 1919. Flexible cloth, 7 x 5 in., 253 pp., 126 illus., 37 tables. $2.50.

The author of this handbook has aimed to provide a clear, concise and practical work on the occurrence of oil and its geology, based on American practice. The present edition, the third since its appearance in 1915, has been thoroughly revised, enlarged and reset.

ACCESSIONS TO THE LIBRARY

Aids to Employment Managers and Interviewers on Shipyard Occupations, with Description of Such Occupations. Special Bulletin. Series on Employment Management in the Shipyard. U. S. Shipping Board Emergency Fleet Corporation. *Philadelphia, 1918.*

American Library Annual. 1917-18. *New York, 1918.* Purchase.

Axioms that Make Armor Plate Roads. *New York, 1919.* Gift of T. Hugh Boorman.

The Barite Deposits of Missouri and the Geology of the Barite Disrrict. By William Arthur Tarr. Univ. of Missouri Studies, Vol. 3, No. 1. Science series. Gift of author.

Bibliography of American Literature Relating to Refrigeration, with Synopsis of Papers and Reports Covering the Year 1915. By Peter Neff, compiled under the direction of the Committee on Papers and Lectures of the American Association of Refrigeration, *Chicago, n. d.* Gift of American Association of Refrigeration.

Boilers and Furnaces Considered in Their Relations to Steam Engineering. By William M. Barr. *Philadelphia, 1899.*

Carnegie Endowment for International Peace. Preliminary Economic Studies of the War. No. 6. Effects of the War upon Insurance with Special Reference to the Substitution of Insurance for Pensions. By William F. Gephart, New York, 1918. No. 7. The Financial History of Great Britain, 1914-1918. By Frank L. McVey. *New York, 1918.* Gift of the Carnegie Endowment for International Peace.

Changing Economic Viewpoints. Gift of Guaranty Trust Company of New York.

Chronocyclegraph Motion Devices for Measuring Achievement. Motion Study and Time Study Instruments of Precision. Motion Models: Their Use in the Transference of Experience and the Presentation of Comparative Results in Educational Methods. [3 pamphlets.] By Frank G. Gilbreth and Lillian Moller Gilbreth.

Civil War Experiences Under Bayard, Gregg, Kilpatrick, Custer, Raulston, and Newberry, 1862-64. By Henry C. Meyer. *New York, 1911.* Gift of Henry C. Meyer.

Cochrane Engineering Bulletin no. 20. The Scientific Treatment of Boiler Feed Water. *1917.* Gift of Harrison Safety Boiler Works.

Combinazioni Chimiche fra Metalli. By Michele Gina and Clara Giua-Lollini. *Milano, 1917.* Purchase.

Development of Magnetic Susceptibility in Manganese Steel by Prolonged Heat Treatment. By Charles F. Brush. (Reprinted from Proceedings of the American Philosophical Society v. 57, 1918). Gift of Author.

Diesel Engine Design. By E. Mortimer Rose. *Manchester, England, 1917.* Purchase.

Dynamic Heating of Air as a Cause of Hot Volcanic Blasts. By G. N. Cole. Reprint from Monthly Weather Review, Oct., 1918. Gift of author.

Economy Hints (2nd enlarged edition) from the Locomotive of the Hartford Steam Boiler Inspection and Insurance Company. Some Thrifty Suggestions for Meeting Your Fuel Emergency. *Hartford, 1918.* Gift of the Hartford Steam Boiler Inspection and Insurance Company.

Electric Light Arithmetic. By R. E. Day. *London, 1882.* Gift of B. F. Simmons.

Engineering Facts and Figures for 1863. An Annual Register of Progress in Mechanical Engineering and Construction. Edited by Andrew Betts Brown. *London, 1864.*

The Ethics of Coöperation. By James H. Tufts. *Boston, 1918.* Gift of University of California Press.

Federal Valuation of the Railroads in the United States. President's Conference Committee. Statement prepared by Frederick H. Lee, Secretary. Developments in connection with Federal Valuation as of November 30, 1918. Gift of Clemens Herschel.

Fifteen Sermons Preached on Various Important Subjects. By George Whitefield. *Glasgow, 1792.*

General Railroad Map Engraved . . . for The Official Guide of the Railways and Steam Navigation Lines of the United States, Porto Rico, Canada, Mexico and Cuba. *New York, 1919.* Purchase.

Guide du Mécanicien d'Aviation. A l'Usage des Mécaniciens, des Elèves Pilotes et des Candidats aux Troupes de l'Aéronautique Militaire. Two volumes. *Paris, n. d.* Purchase.

Handbook on Employment Management in the Shipyard. Dealing with Modern Methods and Practices of Employment Management. Bulletin I. Organizing the Employment Department. U. S. Shipping Board Emergency Fleet Corporation. *Philadelphia, 1918.*

Hendricks' Commercial Register of the United States for Buyers and Sellers. *New York, copyright 1918.* Gift of publisher.

The History and Development of Ball Bearings. *1918.* Gift of The Hess-Bright Manufacturing Co.

Industrial Arts Index. Annual cumulation 6th, 1918. Purchase.

Industrial Development of India. Nov. 3, 1918. Gift of Guaranty Trust Company of New York.

Inspector's Manual for Fuze Assembly. Second Edition. Compiled by Colonel R. Birnie, H. G. Bennett, W. J. Hawkins, J. R. Fifer. *New York, 1918.* Gift of International Arms & Fuze Co.

The Iron and Steel Institute. Carnegie Scholarship Memoirs. Vol. 9. *Lond., 1918.* Purchase.

Manual of Electrical Undertakings and Directory of Officials, 1918-1919. With which is incorporated the Imperial Directory and Statistics of Electric Lighting, Power and Traction Works in Operation or Projected in Great Britain, and Ireland, India, and all British Colonies. Compiled under the direction of Emile Garcke. Vol. 22. *Lond., n. d.* Purchase.

Metallurgia Generale e Siderurgia. Capisaldi e Riassunti. By Umberto Savoia. *Milano, 1919.* Gift of Engineering and Mining Journal.

Minerals and Mining—Nova Scotia. By R. Drummond. *Stellarton, N. S., 1918.* Gift of Hon. E. H. Armstrong.

Mineral Industry. Vol. 26, 1917. McGraw-Hill Book Co., *New York, 1918*. Purchase.

The New Foreign Representative. By Frank H. Taylor. *New York, 1918*. Gift of author.

Oil Fields of Texas. By F. Julius Fohs (Chart.)

Oil Sand Horizons of Texas. By F. Julius Fohs. (Chart.)

On the Motion of Points Constrained and Resisted and on the Motion of a Rigid Body. The Second Part of a new Edition of a treatise on Dynamics. By William Whewell. *Cambridge, 1834*.

Pennsylvania. Bureau of Standards. Annual Report. 8th, 1918. Purchase.

A Plan for the Development of the Village of Grand Canyon, Ariz. By F. A. Waugh, 1918. *Washington, 1918*. Gift of U. S. Department of Agriculture, Forest Service.

Portland Cement Association. Magazine List, October 1918. Gift of Portland Cement Association.

Present and Prospective Supply of Natural Gas Available in Pennsylvania. By Samuel S. Wyer. *1918*. Gift of author.

The Protection of Metals from Oxidation at High Temperatures. By W. E. Ruder. Vol. 1. *1918*. Gift of Diamond Power Specialty Company.

The Quebec Bridge Carrying the Transcontinental Line of the Canadian Government Railways Over the St. Lawrence River Near the City of Quebec, Canada. Gift of George F. Porter.

Radium and Uranium; Their Ores and Occurrence in Nature. By R. A. F. Penrose, Jr. *Albany, 1918*. Gift of author.

Red Cross Institute for Crippled and Disabled Men. Publications. Series 2, No. 4. Employment Opportunities for Handicapped Men in the Coppersmithing Trade. By Bert J. Morris. Gift of the Institute.

The Relative Corrosion of Cast-Iron, Wrought-Iron and Steel Pipe in House-Drainage Systems. By William Paul Gerhard. Gift of author.

Report on Proposed Belle Isle Bridge by the Consulting Board Belle Isle Bridge Division of Engineering and Construction, Department of Public Works, City of Detroit. *1918*. Gift of George H. Fenkell.

Representation in Industry. By John D. Rockefeller, Jr. *1918*. Gift of author.

Rules for the Construction of Stationary Boilers and for Allowable Working Pressures. Report of the Committee to Formulate Standard Specifications for the Construction of Steam Boilers and other Pressure Vessels and for their Care in Service, known as The Boiler Code Committee, The American Society of Mechanical Engineers. Edition of 1918.

The Science of Burning Liquid Fuel. A Practical Book for Practical Men. By William Newton Best. *1913*. Gift of author.

Sherwin's Mathematical Tables. Third edition, carefully revised and corrected by William Gardiner. *London, 1742*. Gift of W. Brokaw Bamford.

A Short Course in Oxy-Acetylene Welding. By Alfred S. Kinsey. Gift of Air Reduction Sales Co., N. Y.

Smoke Regulation. Compiled by Daniel Maloney. Issued by the Dept. of Parks and Public Property of the City of Newark, N. J. Gift of the Department of Parks and Public Property, Smoke Abatement Division, Newark, N. J.

South Dakota School of Mines. Bulletin No. 12. The Occurrence, Chemistry, Metallurgy and Uses of Tungsten with special reference to the Black Hills of South Dakota. By J. J. Runner and M. L. Hartmann. Including a Bibliography of Tungsten by M. L. Hartmann. *1918*. Gift of South Dakota School of Mines.

Steel Alloys Corporation. Gift of Kirby Thomas.

Steel Shipbuilders Handbook. By C. W. Cook. *New York, 1918*.

Tests of Moisture and Water Resistance of Various Coatings on Small Boat Construction. By Henry A. Gardner. Gift of Institute of Industrial Research.

Technical Handbook of Oils, Fats and Waxes. By Percival J. Fryer and Frank E. Weston. vol. 2. Practical and Analytical. *Cambridge, England, 1918*. Purchase.

Tide Levels and Datum Planes on the Pacific Coast of Canada. Supplement No. 1 to the 38th Annual Report of the Dept. of Marine and Fisheries. *Canada, 1906*. Gift of the Department of the Naval Service.

Tides at the Head of the Bay of Fundy. *1917*.

Tide Levels and Datum Planes in Eastern Canada. Published by the Department of the Naval Service. *Canada, 1917*. Gift of the Department.

A Treatise on Mechanics. By Captain Henry Kater and Rev. Dionysius Lardner. *London, 1830*. Gift of Reginald Pelham Bolton.

U. S. Board of Ordnance and Fortification. Annual Report to the Secretary of War. 28th, 1918. *Washington, 1918*. Purchase.

U. S. Bureau of Mines. Annual Report of the Director. 8th, for the year ending June 30, 1918. Purchase.

U. S. Department of Agriculture. Bureau of Chemistry. Report of the Chemist. *Washington, 1918*. Gift of the Bureau.

U. S. Geological Survey. Annual Report of the Director. 39th, 1918. *Washington, 1918*. Purchase.

U. S. Interstate Commerce Commission. Annual Report of the Statistics of Railways in the United States. 29th, 1916. *Washington, 1918*. Purchase.

Université de Liége. Overture Solennelle des Cours le 21 Octobre, 1902. Discours de M. le Recteur V. Dwelshauvers-Dery sur La Machine a Vapeur Moderne. *Liége, 1902*.

THE ENGINEERING INDEX

Published Monthly by The American Society of Mechanical Engineers

The Engineering Index was Founded in 1884 by the Association of Engineering Societies; Published from 1895 to 1919 by The Engineering Magazine Company; and Acquired January 1919 by The American Society of Mechanical Engineers

THE following pages form a descriptive Index to articles on engineering and related subjects in current periodicals. In its preparation the Society's engineering staff regularly examines all of the technical journals and society publications received by the Engineering Societies Library, which form one of the greatest and most complete collections of scientific periodicals in the world, comprising upward of 1100 distinct publications in some ten languages. Cross-references are freely introduced in the Index, and in all cases where the titles of articles are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC COPIES OF ARTICLES LISTED

THE Society is prepared to supply photostatic copies (white printing on brown background) of any of the articles listed. Copies of the periodicals themselves, or clippings of articles, cannot be supplied.

Price of each print (up to 11 x 14 in. in size), 25 cents plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Those holding coupon books for clippings formerly issued by The Engineering Magazine Company may use the coupons in payment for photostatic prints. In ordering, state plainly

(1) Page number of Index on which item appears
(2) Title of article
(3) Name of periodical.

Orders should be sent to

Harrison W. Craver, *Director,*
Engineering Societies Library,
29 West 39th Street, New York City.

DIVISIONS OF THE ENGINEERING INDEX

Mechanical Engineering

ABRASIVES

Microstructure

The Microstructure of Abrasives, J. Scott. Mech. World, vol. 64, no. 1666, Dec. 6, 1918, pp. 266-267, 2 figs. Remarks on physical and chemical phenomena in polishing, grinding and sharpening; photomicrographs of emery cloth and tripoli powder.

AIR MACHINERY

Blowers

Snow Gas Engine Blower at Parkgate Works. Iron & Coal Trades Rev., vol. 98, no. 2657, Jan. 31, 1919, pp. 132-133, 2 figs. Arrangement of twin-tandem gas-driven blowing engine at Parkgate Iron & Steel Works, Rotherdam.

Compressed-Air Application

Compressed-Air in a Shell Plant, R. E. C. Martin and S. B. King. Am. Mach., vol. 50, no. 9, Feb. 27, 1919, pp. 395-396, 3 figs. Illustrates convenience, adaptability and economy of air power for industrial and manufacturing purposes.

Compressors

Hydraulic Air Compressors. (Hydrokompressoren.) Engineer Heinrich. Zeitschr. fuel komprimierte und fluessige Gase, vol. 19, no. 5, June 26, 1918, pp. 45-49, 4 figs. Part II. Conclusion to follow. Describes C. H. Taylor's compressor, German types, Pohle's air-lift pump. Gives the theory of hydro compressors and their efficiency curves derived from tests. Part I in vol. 18, page 33.

Fans

Influence of Blade Inclination on the Power of a Centrifugal Fan (Influence de l'inclinaison des aubes sur la puissance des ventilateurs), M. Karrer. Génie Civil, vol. 73, no. 25, Dec. 21, 1919, pp. 486-489, 6 figs. Mathematical formula for the pressure exerted by blade and graphs showing volume against pressure for various inclinations of the blades.

Lubrication

Lubrication of Air Compressors, H. V. Conrad. Power Plant Eng., vol. 23, no. 5, Mar. 1, 1919, pp. 247-249, and Elec. Ry. Jl., vol. 53, no. 9, Mar. 1, 1919, p. 424. Difficulties encountered; suitable oils; proper quantities.

Pneumatic Delivery

Pneumatic Postal Delivery Systems. (Die Verwendung der Pressluft in der Verkehrstechnik mit besonderer Berücksichtigung der Rohrpost Anlagen), Baurat Kasten. Zeitschrift fuer Komprimierte und fluessige Gase, vol. 19, no. 3, 1917-1918, part 2, pp. 25-29, 8 figs. Compares the systems in use in the various large cities of the world, and claims more efficient performance for the systems in use in Berlin and Munich. Gives diagrams of air pressure fluctuations and switchboards. (To be continued.)

AUTOMOBILES

(See Motor-Car Engineering)

CASE-HARDENING

Shimer's Process

Shimer Case-Hardening Process, Joseph W. Richards. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 437-438, and Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 431-433. Process employs bath of easily fusible noncase-hardening salts (usually a mixture of sodium chloride, calcium chloride, and barium chloride in equal proportions by weight) and fresh calcium cyanide, which latter imparts case-hardening properties.

CORROSION

Rustproofing

Rust-Proofing of Iron and Steel, Elmer S. Whittier. Metal Industry, vol. 17, no. 2, Feb. 1919, pp. 79-82. Description of Parker process.

FORGING

Hollow Forging

Improved Methods of Hollow Forging, S. A. Hand. Am. Mach., vol. 50, no. 9, Feb. 27, 1919, pp. 377-382, 20 figs. Methods described were used in France for making the 75-mm. shell. They have been adapted to American practice and it is asserted that they have been found more economical than former methods.

Smithing

The Engineer's Smithy, Joseph Horner. Mech. World, vol. 65, no. 1673, Jan. 24, 1919, pp. 42-43, 6 figs. Drawing-down process in anvil forging. Tenth installment. (Continuation of serial.)

FOUNDRIES

Brass Foundry Practice

Materials and Chemicals Used in Brass Foundry Practice, Charles Vickers. Brass World, vol. 15, no. 2, Feb. 1919, pp. 35-37, 1 fig. History, properties, appearance, physiological action and commercial use. Feathered tin; phosphor tin; phosphor copper. Third article.

Cores

Core Mixtures for Large Marine Engine Cylinder Cores, John F. Kellogg. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 128-129, 2 figs. Practices followed at various foundries.

Die Casting

Die Castings and Their Application to the War Program, Charles Pack. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 239-248, 9 figs. Survey of developments in manufacture of metal castings by forcing molten metal, under pressure, into a metallic mold or die, with brief descriptions of several casting machines and of methods used to avoid blowholes.

Ferrosilicon

Ferrosilicon as an Aid to the Iron Foundry, W. F. Sutherland. Can. Foundryman, vol. 10, no. 2, Feb. 1919, p. 39. Manufacture and properties of ferrosilicon.

Foundry Design

Foundry and Shops of Striking Design, Charles Lundberg. Iron Age, vol. 103, no. 7, Feb. 13, 1919, pp. 417-422, 11 figs. Result of studious effort to attain ideal in Michigan plant; storage building contains bins for all materials used.

Manganese-Steel Castings

Manufacture of Manganese-Steel Castings, B. S. Carr. Mech. World, vol. 65, no. 1674, Jan. 31, 1919, pp. 56-57. Physical characteristics; heat treatment; cleaning and machining. From Armour Engr.

Pattern Making

Contraction and Expansion, G. W. Lynes. Mech. World, vol. 65, no. 1673, Jan. 24, 1919, pp. 43-44, 4 figs. As affecting patternmaker. Paper before Sheffield Branch British Foundrymen's Assn.

Substitutes

Meeting the Situation with Substitute Formulæ, R. R. Clarke. Brass World, vol. 15, no. 2, Feb. 1919, pp. 47-48. Conditions in foundry industry.

Tool Casting

New Way to Cast High Speed Tools, J. E. Johnson. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 353-360, 6 figs., and Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 435-437, 7 figs. Also Iron Age, vol. 103, no. 8, Feb. 20, 1919, pp. 481-483, 5 figs. The Davidson process and its advantages over method of shaping tools from forgings; the structure of the cast metal.

Waste

Modern Method Applied to the Foundry, W. R. Dean. Metal Industry, vol. 17, no. 2, Feb. 1919, pp. 69-70, 4 figs. Causes of waste; classification and prevention of losses. Second article.

See also MECHANICAL ENGINEERING, Standards and Standardization (Brass and Bronze Foundries); ELECTRICAL ENGINEERING, Furnaces (Rennerfelt Furnace Operation); INDUSTRIAL TECHNOLOGY, Graphite Crucibles.

FUELS AND FIRING

Anthracite

Burning Steam Sizes of Antharcite With or Without Admixture of Soft Coal. U. S. Fuel Administration, eng. bul. 5, 8 pp., 1 fig. Furnace equipment required for burning various percentages of steam anthracite and soft coal.

Ash

The Relation Between the Calorific Values and the Ash-Yields of Coal-Samples from the Same Seam, Thomas James Drakeley. Tran. Instn. Min. Engrs., vol. 56, part 2, Dec. 1918, pp. 45-56 and (discussion) pp. 56-60, 3 figs. From experiments and graphs the following formula is suggested, $y = C\ (1-X)\ S$, where C is a factor for the seam and stands for calorific value of mineral-free coal; S the percentage of ash yielded by impurities; y the required calorific value of sample, and X the percentage of ash yielded by sample.

Blending

The "Sandwich" Sytem of Fuel Blending, E. W. L. Nicol. Colliery Guardian, vol. 117, no. 3030, Jan. 24, 1919, pp. 192-193, 3 figs. Apparatus for mixing various grades of solid fuel as they are fed to burners.

Fuel Blending, E. W. L. Nicol. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 40-41, 3 figs. Arrangement of "sandwich" system designed to cause blending of various grades of solid fuels as they are fed to furnace. Working results are given.

Briquetting

Economy of Briquetting Small Coal, J. A. Yeadon. Mech. World, vol. 64, no. 1668, Dec. 20, 1918, pp. 293. Abstract of paper before Min. Inst. Scotland.

Combustion Control

Combustion and Flue Gas Analysis. U. S. Fuel Administration, eng. bul. 4, 12 pp., 5 figs. Combustion-control apparatus; necessity of instructions to firemen.

Control of Combustible and Air in Burning Powdered Coal, W. G. Wilcox. Power Plant Eng., vol. 23, no. 5, Mar. 1, 1919, pp. 237-239. From a paper before the Western New York Section of the American Chemical Society.

Fuel Conservation

Fuel Conservation. Southern & Southwestern Ry. Club, vol. 14, no. 12, Nov. 1918, pp. 10-20 and (discussion) pp. 20-38. Discusses necessity of locomotive maintenance, constant education of enginemen and firemen, coöperation and necessity of complete understanding of importance of fuel conservation by operating officials.

Fuel Utilization. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 24. Reviews of efforts in coal conservation, particularly pulverizing coal and oil production and gas works.

Methods for More Efficiently Utilizing Our Fuel Resources, C. G. Gilbert and J. E. Pogue. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 149-151. Part 25. The need for a constructive economic policy in developing the coal products industry. Extract from U. S. National Museum Bulletin 102, Part 5; "Power: Its Significance and Needs," 1918.

Worcester's Fuel Saving Campaign, S. E. Balcome. Power Plant Eng., vol. 23, no. 5, Mar. 1, 1919, pp. 236-237, 2 figs. First article of a series on the organization, work of committees and results obtained in industrial plants.

Conservation of Fuel, D. C. Randolph. Proc. Central Ry. Club, vol. 27, no. 1, Jan. 1919, pp. 529-536 and (discussion) pp. 536-554. Contrasts what are termed good and bad railway fuel practices in locomotives, shops, roundhouses, yards and on the road.

Gas and Oil Fuels

See Producer Gas, page 8a; items under INDUSTRIAL TECHNOLOGY; and Oil, under MINING ENGINEERING.

Low-Grade Fuels

On the Utilization of Low-Grade Fuels at the Montrambert Collieries (Note sur l'utilisation des combustibles pauvres par la société des houillères de Montrambert). Bulletin de la Société d'Encouragement, vol. 130, no. 6, Nov.-Dec. 1918, pp. 376-378. Materials tested contain 42 to 50 per cent ash and 18 to 20 per cent volatile matter.

Motor-Car Fuel

Gas as Automobile Fuel (L'emploi du gaz dans les automobiles), A. Grebel. Génie Civil, vol. 74, no. 5, Feb. 1, 1919, pp. 81-84, 11 figs. Applications in France and in England; experiments of the Société du Gaz, Paris.

Fuel. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 356-357. Possibilities of benzol, alcohol and shale distillate as substitutes for gasoline.

An Interpretation of the Engine-Fuel Situation, Joseph E. Pogue, Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 357-361, 3 figs. Believes that lesser gasoline output, which writer considers as inevitable, can be met only by modifying engine design so as to secure higher thermal efficiency and to use less specified fuel.

Pacific Coast

Fuel Problems of the Pacific Coast. Mech. Eng., vol. 41, no. 3, Mar. 1919, pp. 264-269 and 292. Possibilities of fuel-oil conservation through its economic utilization and development of hydraulic power.

Peat

Possibilities of Peat, C. C. Osborn. Jl. Am. Peat Soc., vol. 12, no. 1, Jan. 1919, pp. 7-16 and 17-47. General conditions in industry; production in U. S., 1908-1917; manufacture of peat products; occurrence properties and uses; comparative calorific value of peat and other fuels; methods of preparation; peat industry in principal foreign countries. From U. S. Geol. Survey.

Powdered Coal

A Review on the Use of Powdered Coal, W. O. Renkin. Blast Furnace, vol. 7, no. 2, Feb. 1919, pp. 114-116 and 119, 3 figs. Graph showing comparative value and advantages of different fuels: comparison of installation and operating costs of producer gas, natural gas and hand-fired coal; early uses of powdered coal.

Powdered Coal as a Substitute for Fuel-Oil, Min. & Sci. Press, vol. 118, no. 7, Feb. 15, 1919, pp. 235-236, 1 fig. Layout of experimental plant using Buell-Santmyer system.

Pulverized Coal and Its Utilization, H. G. Barnhurst. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 45-46. Developments in pulverized-coal burning; plants using pulverized coal.

Pulverized Coal in an Industrial Plant, C. A. Dille. Power Plant Eng., vol. 23, no. 4, Feb. 15, 1919, pp. 188-189, 1 fig. Its preparation and method of application at plant of Mansfield Sheet and Tin Plate Co.

Characteristics of Powdered Coal, W. G. Wilcox. Brick & Clay Rec., vol. 54, no. 2, Jan. 28, 1919, pp. 127-131. Essentials of good combustion; flame length and air control; mixing coal with air; velocity of combustion.

U. S. Fuel Administration

Distribution of Coal Under U. S. Fuel Administration, J. D. A. Morrow. Bul. Am. Inst. Min. Engrs., no. 147, Mar. 1919, pp. 585-589. Method of controlling directing distribution.

Work of National Production Committee of U. S. Fuel Administration, James B. Neale. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 439-444. Method adopted for increasing production; need of stimulating ambition in workmen; industrial obligations of employers to men.

Wet Coal

Birds Nesting of Boiler Tubes, James Scott. Nat. Engr., vol. 23, no. 2, Feb. 1919, pp. 66-67, 3 figs. Suggests avoidance of wet coal highly impregnated with sulphur; also suppression of very high temperatures until sulphur has volatilized away. From Practical Engr.

FURNACES

Annealing Furnaces

Heating Furnaces and Annealing Furnaces—II and III, W. Trinks. Blast Furnace, vol. 7, nos. 2 and 3, Feb. 1919 and Mar. 1919, pp. 98-101, 9 figs., and pp. 134-137, 7 figs. Speed of heat transmission and required brick surface; curves showing rate of heat abstraction from exterior of furnace.

Heating Furnaces

Practical Pointers on Heating Furnaces, George J. Hagan. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 153-155 and 163. Changes in hearth areas capacities and walls to improve product and reduce losses. Paper before Engrs.' Soc. Western Pa.

Kilns

Ovens and Kilns With a High Thermal Efficiency, A. Bigot. Engineering, vol. 107, no. 2768, Jan. 17, 1919, pp. 80-82, 6 figs. Paper before Refractory Materials Section of Ceramic Soc.

Open-Flame Furnaces

Open-Flame Furnaces at Government Gun Plant Accomplish Results That Munitions Specialist Believed Possible Only with Muffled Furnace or Electric. Am. Gas Eng. Jl., vol. 110, no. 5, Feb. 1, 1919, pp. 91-94, 4 figs. Large units measuring 37 ft. in depth and 9.5 ft. outside diameter are used to heat-treat big guns.

HANDLING OF MATERIALS

Coaling Station

Coaling Stations of the Philadelphia & Reading Railway. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 47-49, 6 figs. $270,000 locomotive coaling plant arranged to handle both anthracite and bituminous coal.

Coal Yard

An Efficient Chicago Coal Yard. Black Diamond, vol. 62, no. 4, Jan. 25, 1919, p. 65, 3 figs. Operates auto-crane in place of having elevated tracks.

Paper Mill

Handling Material in a Paper Mill, Henry J. Edsall. Indus. Man., vol. 57, no. 3, Mar. 1919, pp. 183-189, 18 figs. Boilerhouse machinery, conveyors for wet and dry pulp, machinery for handling black ash; track hauler, monorails and cranes. (Concluded.)

Steel Works

Handling Fuel and Materials in Iron and Steel Works, Frank Somers. Colliery Guardian, vol. 117, no. 3029, Jan. 17, 1919, p. 141. Concerning avoidance of passing materials backwards. Paper before Staffordshire Iron & Steel Inst.

GAGES

Limit Gages

Limit Gages, W. E. Wilson. Mech. World, vol. 65, no. 1672, Jan. 17, 1919, p. 27. Correction of gages for wear. First installment. (To be continued.) From Commonwealth Engr.

HEAT TREATING

Critical Points

Critical Points. Proc. Steel Treating Research Soc., vol. 2, no. 2, 1919, pp. 32-40, 1 fig. Discussions held before Detroit section on shrinkage and warpage in hardening steel parts and on development of soft spots in case hardened parts.

Low-Carbon Steel

Heat Treatment of Low-Carbon Steel, W. M. Wilkie. Mech. Eng., vol. 41, no. 3, Mar. 1919, pp. 239-244, 12 figs. Photomicrographs showing change in grain structure caused by annealing to various temperatures; effect of these structures on quality of steel.

Mass, Effect of

Effect of Mass on Heat Treatment, E. I. Law. Proc. Steel Treating Research Soc., vol. 2, no. 2, 1919, pp. 11-18 and (discussion) pp. 18-19 and 31, 3 figs. Chemical analyses, heating and cooling curves, and mechanical tests of cubes taken from 25-in. square ingot 10 ft. long after it was cogged down to 18 in. square. Paper before Iron & Steel Inst.

Springs

Manufacture, Heat Treatment and Physical Tests of Automobile Springs, N. E. Hendrickson. Proc. Steel Treating Research Soc., vol. 1, no. 10, July 1918, pp. 39-42 and (discussion) pp. 42-44. Calls attention to inconsistency of combining high-grade material with poor workmanship or heat treatment.

Steel Selection

The Composition and Properties of Steels, Howard Ensaw. Mech. World, vol. 65, no. 1671, Jan. 10, 1919, pp. 15-17. Suggests selection of few types of steel in order to avoid error in hardening and tempering. Tests of physical and chemical properties of steel.

Tempering

Phases on Tempering, E. W. Upham. Iron & Steel Can., vol. 2, no. 1, Feb. 1919, pp. 25-27. Discussion of methods of treatment and temperature control. Paper before Steel Treating Research Soc.

See also *METALLURGY, Iron and Steel (Aging Break).*

HEATING AND VENTILATION

Economics

Engineering Economics of Heating, M. William Ehrlich. Heat. & Ventilating Mag., vol. 16, no. 2, February, 1919, pp. 17-23, 6 figs. Containing also a method of predetermining coal requirements for steam and hot water heating systems. Abstract of a paper presented at the annual meeting of the American Society of Heating and Ventilating Engineers, New York, January, 1919.

Electricity

Heating Our Homes with Electricity. Elec. News, vol. 28, no. 3, Feb. 1, 1919, pp. 23-25 and 30, 7 figs. Pioneer installation in Toronto said to prove that electric heating is practical.

Heating Plants

The Enormous Heating Plant at the Great Lakes Naval Training Station, J. C. Foster. Domestic Eng., vol. 86, no. 7, Feb. 15, 1919, pp. 299-300. Plant supplies heat to 950 buildings covering area of 1210 acres.

Low-Pressure System

Saving Steam in Industrial Heating Systems. U. S. Fuel Administration, eng. bul. 6, 14 pp., 9 figs. Suggests utilization of exhaust steam and discusses chief requirements for a good low-pressure heating system.

See also *MINING ENGINEERING, Mines and Mining (Ventilation).*

HOISTING AND CONVEYING

Conveyors

Conveyors in Relation to Engineering Works, W. W. Atherton. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 27-30, 4 figs. Illustrations showing various types of conveyors.

Floating Cranes

Floating Crane of 75-Ton Capacity. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 63-64, 1 fig. Dimensions and arrangement of auxiliary parts.

Grain Elevators

Some Modern German Grain Elevators (Neuzeitlicher deutscher Getreidespeicherbau), Prof. M. Buhle. Zeitschrift fuer Baumwesen, vol. 68, no. 7 to 9, 1918, pp. 3195-314, 19 figs. Gives views and details of mechanical equipments of a number of grain elevators erected in Germany, Austria, Russia and Holland.

Wall Cranes

Wall Cranes, Ernest G. Beck. Mech. World, vols. 64 and 65, nos. 1669 and 1674, Dec. 27, 1918, and Jan. 31, 1919, pp. 306-307 and 54. Computation of stresses in members. Twentieth and twenty-first installments. (Concluded.)

HYDRAULIC MACHINERY

China

Age-Long Engineering Works of China. Middleton Smith. Engineer, vol. 127, no. 3291, Jan. 24, 1919, pp. 72. A description of some of the ancient hydraulic works in China.

Gates

Automatic Gates a Factor in Safety of Spillway Dams, Robert H. Moulton. Safety Eng., vol. 37, no. 2, Feb. 1919, pp. 58-60, 4 figs. Gates are operated by the water pressure.

INTERNAL-COMBUSTION ENGINES

Diesel Engine

The Diesel Engine on Shipboard, Bruce Lloyd. Jl. Electricity, vol. 42, no. 3, Feb. 1, 1919, pp. 116-119, 5 figs. Discussions of results obtained in trials on vessels built in Pacific Coast. Writer's opinion concerning marine acceptance of Diesel engine. Paper before San Francisco Section, Am. Soc. Mech. Engrs.

The Diesel Engine—I, Herbert Haas. South. Engr., vol. 30, no. 6, Feb. 1919, pp. 48-50, 4 figs. Three general types of liquid-fuel engines; explosion engines having four-stroke cycle; engines having two-stroke cycle.

Junkers Engine

The Junkers Engine, Philip Lane Scott. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 112-114, 4 figs. Operation of engine (Diesel type) having two pistons in one cylinders.

Semi-Diesel Engine

Combustion Engines and Their Applications (Les moteurs à combustion et leurs applications), M. Droesne. Revue Générale des Sciences, vol. 29, no. 23, Dec. 15, 1918, pp. 666-673, 1 fig. Origin and development of semi-Diesel engines; survey of results obtained in France and elsewhere in the construction of Diesel engines of various types.

The Leading Features of Semi-Diesel Oil Engine, James Richardson. Mar. Eng. Can., vol. 8, no. 12, Dec. 1918, pp. 295-300, 10 figs. Definition; nomenclature; classification; compression pressure; effect of compression; cycle of operation.

See also *MARINE ENGINEERING, Ships (Motorships).*

LUBRICATION

Grinding Lubricants

Proper Care of Grinding Lubricants, Howard W. Dunbar. Iron Trade Rev., vol. 64, no. 6, Feb. 6, 1919, p. 375. Contends that a tank for each machine is best way to handle grinding compounds and lubricants.

Lubricating Oils

Lubricating Oils, G. R. Rowland. Nat. Engr., vol. 23, no. 2, Feb. 1919, pp. 68-71, 1 fig. Physical characteristics and application; selection of oil most suitable for work required; distillation.

MACHINE ELEMENTS AND DESIGN

Bearings, Thrust

Single-Collar vs. Multi-Collar Thrust Bearings for Propeller Shafts, H. G. Reist. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 133-137, 3 figs. From data available author assumes that substituting of single for multi-collar thrust bearings on average merchant ship would result in saving about one-half of one per cent of the total power, coal and size of boilers.

Flywheels

How Much Should a Flywheel Weigh? Rufus T. Strohm. Power, vol. 49, no. 8, Feb. 25, 1919, pp. 269-273, 7 figs. Simple method of calculating approximately weight of flywheel.

Gears

The Properties of Worm Axle Gears. Machinery, vol. 13, no. 331, Jan. 30, 1919, pp. 479-480. Formulæ and calculations.

Springs

Calculation of Helical Springs. (Berechnung zylindrischer Schraubenfedern unter Verwendung von Schaulinien.) Richard Seeman. Dinglers Polytechnisches Journal, vol. 333, no. 11, June 1, 1918, pp. 91-96, 11 figs., 5 tables. Concluded in no. 12, June 15, 1918, pp. 99-101. Large diagrams for solving all usual problems occurring with helical compression and tension springs. The second part contains typical examples, considering also the element of time, as in the closing of valves.

MACHINE SHOP

Boring and Lining

War-Time Repairs in the Navy, Frank A. Stanley. Am. Mach., vol. 50, no. 9, Feb. 27, 1919, pp. 383-387, 14 figs. Boring and lining operations. Fifth article.

Control of Tools

The Control of Electrically Operated Machine Tools, F. Ashton. Mech. World, vols. 64 and 65, nos. 1663, 1665, 1668, 1669, 1671 and 1672, Nov. 15, 29, Dec. 20, 27, 1918, Jan. 10

and 17, 1919, pp. 236-237, 259-260, 292-293, 304-305, 20-21 and 28-29, 17 figs. Description of various types in use; remarks on their operation; methods of starting; dangers from overloads.

Drive

Industrial Motor Installation, W. H. Wakeman. Southern Engr., vol. 30, no. 6, Feb. 1919, pp. 56-59, 10 figs. Detail of construction work in changing from belt drive to electric drive.

Grinding

Grinding as a Machine Operation. Ry. Gaz., vol. 30, no. 1, Jan. 3, 1919, pp. 25-27, 3 figs. Suggestions in regard to designing and operating grinding machines.

Grouting of Machine Bases

Grouting Electrical Machinery Bases—1, Terrell Croft. Southern Engr., vol. 30, no. 6, Feb. 1919, pp. 52-55, 3 figs. Function of grouting; mixing the grout; various materials for grout; preparing a machine bedplate for grout.

Hammering

Handier Hammering. Sci. Am., vol. 120, no. 9, Mar. 1, 1919, p. 208, 2 figs. Hammer provided with device to hold nail.

Shaft Pressing

Recent Developments in Shaft Pressing at Destination, N. L. Rea. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 138-140, 3 figs. Description of methods that have been found successful in pressing on shafts at destination.

See also MECHANICAL ENGINEERING, Lubrication (Grinding Lubricants); RAILROAD ENGINEERING, Shops; METALLURGY, Iron and Steel (Tool Steel); INDUSTRIAL TECHNOLOGY, Pickling.

MACHINERY, METAL-WORKING

Drills

A New Method of Gang Drilling. Iron Age, vol. 103 no. 8, Feb. 20, 1919, pp. 489-492, 7 figs. Radical design based on detachable drill heads and chain drive; cutting cycle automatic; application in boiler shop.

Lathe, Roll

Japan to Have Massive Roll Lathe. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 451-452, 1 fig. Tool is motor-driven and is provided with several spindle speeds; bed is made in sections to facilitate transportation; total weight, 275,000 lb.

Lathe, Screw-Cutting

High-Precision Screw-Cutting Lathe. Mech. World, vol. 64, no. 1667, Dec. 13, 1918, p. 282, 1 fig. Machine built by Commission of Machine Tool Dept., Ministry of Munitions. Among other features "live" center is "dead," drive being obtained by catchplate revolving about spindle extension.

Milling Machine

Double-Spindle Milling Machine for Wrench Slot in Detonator Socket. Machinery, vol. 13, no. 331, Jan. 30, 1919, p. 495. 2 figs. Described as permitting manufacture of 4000 to 5000 fuse parts per day.

Trimmer

Bliss Flat-Edge Trimmer for Sheet Metal. Am. Mach., vol. 50, no. 9, Feb. 27, 1919, pp. 412-414, 4 figs. Description of a machine that will trim the scrap from metal stampings and leave a smooth, flat edge suitable for soldering, welding, brazing or other operations.

MACHINERY, SPECIAL

Evaporators

Industrial Vacuum Evaporators, Frank Coxon. Mech. World, vol. 65, nos. 1670 and 1673, Jan. 3 and 24, 1919, pp. 5 and 40, 7 figs. Classification and description. First and second installments. (To be continued.)

Reversing Machine

Reversing Value of Water-Sealed Type. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 452 and 467, 1 fig. Reversal of 36-in. hand-operated furnace valve is accomplished by a balanced hood and counterweights.

Trench-Digging Machine

German Excavating Machine for Tunnels and Mine Galleries (Machine allemande pour le creusement des tunnels et des galeries de mines), Francis Schmitt. Génie Civil, vol. 73, no. 22, Nov. 30, 1918, pp. 421-423, 10 figs. Details of excavator and of shaft with spiral blade for automatic removal of material.

MATERIALS OF CONSTRUCTION AND TESTING OF MATERIALS

Alternating Stresses

Effect of Cold-Working and Rest on Resistance of Steel to Fatigue Under Reversed Stress, H. F. More and W. J. Putnam. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 391-404, 9 figs. Report of research under auspices of Nat. Research Council.

Cast Iron

Cast Iron in Bending; Variation in Beam Strength, J. Harland Billings. Can. Machy., vol. 21, no. 7, Feb. 13, 1919, pp. 162-163, 2 figs. Tests to determine effect of varying cross section upon strength of beams in bending.

Glass

Strength Tests of Plain and Protective Sheet Glass, T. L. Sorey. Jl. Am. Ceramic Soc., vol. 1, no. 11, Nov. 1918, pp. 801-808, 4 figs. Claims that in both impact and cross-bend tests blown window glass was stronger than plate glass.

Toughness

Static, Dynamic, and Notch Toughness, Samuel L. Hoyt. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 339-351, 10 figs. Considers toughness as an independent property and proposes quantitative determinations of toughness by notched-bar impact tests (Charpy tests).

See also RAILROAD ENGINEERING, Rolling Stock (Lumber for Car Construction); METALLURGY, Iron and Steel (Aging Break)

MEASUREMENTS AND MEASURING APPARATUS

Dynamometers

Commercial Dynamometers, P. Field Foster. Mech. World, vol. 65, no. 1670, Jan. 3, 1919, pp. 6-7, 2 figs. "Transmission" types. Eighth installment. (Continuation of serial.)

Screw Measurements

A Machine for Measuring Screws, P. E. Shaw. Engineering, vol. 107, no. 2769, Jan. 24, 1919, pp. 104-108, 16 figs. Methods described depend upon a simple point contact in all cases. The machine used deals with the diameters and the pitch and is of a simple type, easy to use.

Spherometers

Mechanical Measure of a Spherical Surface. Spherometers. (Mesure mécanique d'une aire sphérique. Les sphérimètres), Paul Vanet. Génie Civil, vol. 74, no. 5, Feb. 1919, p 96, 6 figs. Principle of planimeter applied to measurement of area of closed figure drawn on a spherical surface.

Temperature Measurements

Measuring Gas Temperatures in Boiler Settings. Engineering, vol. 107, no. 2768, Jan. 17, 1919, pp. 75, 1 fig. Abstract of Bulletin 145, U. S. Bureau of Mines, by Messrs. Kreisinger and Barkley.

New Method of Measuring High Temperatures by the Coloration of the Light Emitted by an Incandescent Body (Sur une nouvelle méthode de mesure des températures élevées d'après la coloration de la lumière emise par le corps incandescent), A. Boutaric. Revue Générale de l'Electricité, vol. 5, no. 6, Feb. 8, 1919, pp. 210,217, 7 figs. Based principally on researches by Paterson and Dudding. (Phil. Mag., vol. 30, July 1915, p. 34.)

On the Lags of Thermometers with Spherical and Cylindrical Bulbs in a Medium Whose Temperature Is Changing at a Constant Rate, A. R. McLeod. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919. pp. 134-144. Gives expressions for steady values of lags when surface conductivity is finite, and for lags at any instant when surface conductivity is infinite. Expression for surface conductivity $h = 0.0000515\ V$, where V is miles per hour, is suggested for thermometers moving through air at aeroplane speeds.

MECHANICAL PROCESSES

Bakelite Products

Making Moulded Bakelite Products. Machinery, vol. 13, no. 331, Jan. 30, 1919, pp. 481-485, 9 figs. Concerning design and manufacture of dies with provision for heating with steam.

Boilers

How to Design and Lay Out a Boiler—IV, William C. Strott. Boiler Maker, vol. 19, no. 2, Feb. 1919, pp. 46-47, 2 figs. Size of rivets; efficiency of joint. (Continuation of serial.)

Briquets

Notes on the Manufacture of Briquets, E. H. Robertson. Colliery Guardian, vol. 117, no. 3029, Jan. 17, 1919, pp. 136-137, 3 figs. Rolls for briquetting; cohesion testing machine and arrangement of bars. From Tran. Min. Geol. Inst. India.

Copper Driving Bands

The Manufacture of Copper Driving Bands, Wm. J. Reardon. Metal Industry, vol. 17, no. 2, Feb. 1919, pp. 63-68, 6 figs. How wartime needs developed way to produce pure copper castings in large quantities.

Crushing

Fine Crushing in Ball-Mills, E. W. Davis. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 111-156, 17 figs. Theoretical mechanics of fine crushing, ball-wear formulæ, and operating tests on siliceous rock comprising 35 per cent magnetite, the remainder being chiefly quartzite and iron silicates.

Presses

Manufacturing the Whitlock Pony Press, Robert Mawson. Can. Machy., vol. 21, no. 7, Feb. 13, 1919, pp. 159-161, 9 figs. Jigs and fixtures intended to simplify machining operations.

Rolling Mills

Builds Huge Plate Mill for Japan. Iron Trade Rev., vol. 64, no. 6, Feb. 6, 1919, pp. 387-388, 1 fig. 180-in. plate mill recently built by Morgan Eng. Co., Alliance, Ohio.

Novel Plate Turnover for Tandem Mill. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 128-129, 2 figs. Arrangement at Youngstown Sheet & Tube Co.'s plate mill.

The Strip Mills of Trumbull Steel Co. Iron Age, vol. 103, no. 8, Feb. 20, 1919, pp. 475-479, 5 figs. Hot mill of wide range of speeds; interesting arrangement of finishing stands; motor speed control a feature.

Tractors

Manufacturing the Caterpillar Tractor, Frank A. Stanley. Am. Mach., vol. 50, no. 7, Feb. 13, 1919, pp. 299-302, 7 figs. Cylinders, pistons and crankshafts. Sixth article.

Wheels, Car

Slick Machines for Rolling Car Wheels at Johnstown Mill of Cambria Steel Company (Le laminage des roues de wagons par les machines Slick, aux usines de la Cambria Steel Co. à Johnstown, Pensylvanie, E.-U.), P. Calfas. Génie Civil, vol. 73, no. 24, Dec. 14, 1918, pp. 461-466, 18 figs. Description of a process of making car wheels in which they are formed directly from large rolled bars by a rolling-forging process as applied at the Cambria Steel Works.

See also MECHANICAL ENGINEERING, Heat Treating (Springs), Wood and Timber (Veneer Manufacture); ELECTRICAL ENGINEERING, Furnaces (Manufacture).

MECHANICS

Beams

Theory of the Hyperstatic Beam (Théorie de la poutre hyperstatique), D. Wolkowitsch. Génie Civil, vol. 74, no. 5, Feb. 1, 1919, pp. 84-89, 7 figs. Simple beam supported at one end and fixed at the other; continuous beams on supports at same level. (Concluded.)

Ropes, Wire, Stresses in

Stresses in Wire Rope, Shortridge Hardesty. Mech. Eng., vol. 41, no. 3, Mar. 1919, pp. 257-260, 4 figs. Development of new formula for determination of bending stresses.

Shafts, Critical Velocity of

On the Critical Velocity of Shafts. Dunkerley's Formula (Note sur la vitesse critique des arbres. Formule de Dunkerley), E. Hahn. Revue Générale de l'Electricité, vol. 5, no. 4, Jan. 25, 1919, pp. 123-130, 3 figs. Demonstration of Dunkerley's formula and calculation of its accuracy.

Struts

Critical Distributed Loads for Long Struts, Arthur Morley and F. F. P. Bisacre. Engineering, vol. 107, no. 2769, Jan. 24, 1919, pp. 99-100, 2 figs. Deals mainly with the compression flange or member of cantilevers or masts, developing a general formula applicable to a wide variety of distributed loads.

See also ELECTRICAL ENGINEERING Transmission, Distribution, Control (Suspension, Aerial).

MOTOR-CAR ENGINEERING

Axles

Parker Silent Internal Gear Axle. Automotive Industries, vol. 40, no. 6, Feb. 6, 1919, pp. 305-306, 3 figs. Gear is completely enclosed and runs in oil bath.

Carburetors

New Sunderman Carburetor Uses Floating Venturi. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, p. 377, 5 figs. Employs mushroom jet and air bypass for regulating depression at nozzle.

Design

Effect of Airplane Construction on the Automobile, O. E. Hunt. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 53-55. Claims that most important contribution has been the stimulus to thought of industry.

Possible Effect of Aircraft Experience on Automobile Practice, Howard C. Marmon, O. E. Hunt and Henry M. Crane. Automotive Industries, vol. 40, no. 6, Feb. 6, 1919, pp. 317-322. Comparison of plane and automobile engines; applicability to automobile manufacture of experience gained in producing light-weight results; development of alloy pistons. Paper before Soc. Automotive Engrs.

RILEY
UNDERFEED
STOKERS
A Peak Load Stoker
The evening peak at the Worcester Electric Light Co. calls for $2\frac{1}{2}$ to $3\frac{1}{2}$ times the normal output of the boilers. The RILEY STOKERS not only respond instantly but better still give sustained uniform performance regardless of poor coal or other trying conditions.
The Chief Engineer says *"Without moving grates* or the *continuous automatic ash discharge* such results are impossible." The engineer must know for he has operated many types of stokers.
If you are not acquainted with the advantages of the RILEY STOKER with its live grate surface, then you should send for catalog A-4.
SANFORD RILEY STOKER CO.
WORCESTER, MASS.
British Licensees: Erith's Engineering Co., Ltd., London.
French Licensees: Erith, Leroy & Cie., Paris, France.
Installation of 14-retort Riley Stokers under 1250 H. P. boilers.

Engines

Motor Transport Under Difficulties, J. A. L. Gallard. Min. Mag., vol. 20, no. 2, Feb. 1919, pp. 90-91. Service given by sleeve-valve engine under stresses of war conditions.

Continental Adaptation of Class B War Truck Engine. Automotive Industries, vol. 40, no. 4, Jan. 23, 1919, pp. 211-213, 8 figs. Engine has aluminum crankcase and bell housing; designed originally for military use.

Gray Victory Four-Cylinder Engine. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 370-371, 5 figs. Block-cast engine of 3½-in. bore by 5 in. stroke, of valve-in-head type. Intended for passenger cars, trucks and tractors.

Ricardo Engine "Made Good" in Tanks. Automotive Industries, vol. 40, no. 8, Feb. 20, 1919, pp. 407-410, 7 figs. Piston design; means for cooling piston, for preheating carburetor air, and for preventing unvaporized fuel getting into crank chamber.

Fans

Radiator Cooling Fans, Louis Schwitzer. Automotive Industries, vol. 40, no. 4, Jan. 23, 1919, pp. 202-205. Fan design, mounting and drive; location of fan relative to housing.

Governors

Truck and Tractor Engine Governors, R. B. Shoop. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 374-375 and 392, 8 figs. Classification of various types; factors affecting design; adaptation of marine type.

Hotchkiss Drive

An Analysis of the Hotchkiss Drive, Otto M. Burkhardt. Automotive Industries, vol. 40, no. 4, Jan. 23, 1919, pp. 206-208, 5 figs. Resultant of weight carried and torque or brake reaction; effect of torque on spring.

Motorcycles

Harley-Davidson Co. Brings Out Sport Model. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 362-364, 6 figs. Design having a two-cylinder opposed engine, multiple-disk clutch and three-speed transmission.

Standards

S. A. E. Discusses Truck Subjects, B. B. Bachman, Cornelius T. Myers and G. E. Randles. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 349-351. Pneumatic tires for trucks; recommended inflation pressures.

Tractors

Case 15-27 Hp. Tractor, P. M. Heldt. Automotive Industries, vol. 40, no. 5, Jan. 30, 1919, pp. 256-261, 9 figs. Features of construction. Main frame is single iron casting designed to serve as main part of transmission case, crankcase and rear-axle housing.

Operating a Traction Engine, Thomas G. Thurston. Nat. Engr., vol. 23, no. 2, Feb. 1919, pp. 60-63, 2 figs. What is included in field operations; skill required in making repairs from scant and unsuitable materials.

Principles of the Wheeled Farm Tractor, Edward R. Hewitt. Automotive Industries, vol. 40, no. 6, Feb. 6, 1919, pp. 312-315, 3 figs. Factors determining maximum traction obtainable; results of experiments to ascertain rolling resistance. Paper before Soc. Automotive Engrs.

Valves

Small Inlet Valves Satisfactory in Overhead Valve Design—I, L. H. Pomeroy. Automotive Industries, vol. 40, no. 8, Feb. 20, 1919, pp. 432-435, 6 figs. Report of tests made with two engines of approximately same size, one a valve-in-head design and the other an L-head with valves side by side in valve pocket. Paper before Instn. Automobile Engrs.

Windshields

A New Windshield for Closed Bodies, George J. Mercer. Automotive Industries, vol. 40, no. 8, Feb. 20, 1919, pp. 416-417, 3 figs. Upper and lower parts in inclined planes cutting each other in line of vision.

See also AERONAUTICS, *Engines (Carburetors)*; MECHANICAL ENGINEERING, *Fuels and Firing (Motor-car Fuels), Standards and Standardization (Motor-car Parts)*; INDUSTRIAL TECHNOLOGY, *Gasoline*.

PIPE

Standards

Pipe Standards and Their Application to Commercial Work, A. M. Houser and C. C. Bartlett. Power Plant Eng., vol. 23, no. 5, March 1, 1919, pp. 250-252, 8 figs. Theoretical standards; Briggs standard gage; making tight joints.

POWER GENERATION

Argentina

Utilization of Waterfalls (Aprovechamiento de las caídas de aqua), A. Di Ció. Boletin de la Asociacion Argentina de Electro-Tecnicos, vol. 4, no. 9, Sept. 1918, pp. 816-820. Popular discussion of economical aspect of problem.

France

Hydraulic Energy in the Central Group of France (L'énergie hydraulique dans le Massif Central de la France), P. Morin. Revue Générale de l'Electricité, vol. 5, no. 6, Feb. 8, 1919, pp. 219-227, 4 figs. Geographical conditions and study of the water courses which are susceptible of immediate utilization.

Maine

Cost of Hydroelectric Development. Elec. Wld., vol. 73, no. 9, March 1, 1919, pp. 413-417. From a report based on the study of Maine water powers by H. K. Barrows to the Maine Public Utilities Commission. Effect of load factor; costs of water rights, power transmission lines, storage reservoirs; comparative utility of hydraulic and steam power.

Tennessee

The Larger Undeveloped Water-Powers of Tennessee, J. A. Switzer. Tennessee Geol. Survey, bul. 20, 1918, 55 pp., 30 figs. Report of field and office work; general scheme of development. Paper before Am. Electrochem Soc.

United States

Water Powers, O. B. Wilcox. Nat. Elec. Light Assn. Bul., vol. 6, no. 2, Feb. 1919, pp. 55-56. Estimate of available water power in U. S. From report of chairman of Committee on Public Service Securities, Investment Bankers' Assn. Am.

POWER PLANTS

Boiler Design

Modern Boiler Practice, F. A. Combe. Jl. Eng. Inst. Can., vol. 2, no. 2, Feb. 1919, pp. 109-119, 9 figs. Outline of principles governing boiler and furnace design, with review of present knowledge of laws related thereto, and trend of modern practice, together with general notes regarding boiler installation and operation.

Boiler Testing

Boiler and Furnace Testing, Rufus T. Strohm. U. S. Fuel Administration, Bur. of Conservation, eng. bul. 1, 20 pp., 3 figs. Suggests tests to be made everyday and apparatus required for making them.

Boilers, Uptakes for

How to Lay Out a Large Uptake for Stationary Boilers, Phil Nesser. Boiler Maker, vol. 19, no. 2, Feb. 1919, pp. 42-45, 7 figs. Method saves job of shearing.

Condensers

Condenser Engineering Practice, D. D. Pendleton. Mech. World, vols. 64 and 65, nos. 1669 and 1673, Dec. 27, 1918, and Jan. 24, 1919, pp. 309-310 and 41. Hotwell of low-type jet machine; air in surface condensers; heat transfer in surface condensers. Abstract of paper presented to Assn. Iron & Steel Elec. Engrs.

Vacuum Trouble in Turbine Condensers, James Brakes, Jr. Power, vol. 49, no. 8, Feb. 25, 1919, pp. 287-288, 4 figs. Discussion of an article "Keeping Up Condenser Performance," Power, Dec. 17, 1919.

Cost

Power Plant Costs Committee. Nat. Engr., vol. 23, no. 2, Feb. 1919, pp. 90-95, 4 figs. N.A.S.E. committee cost and production sheets.

Draft

Mechanical Draft, Charles L. Hubbard. Southern Engr., vol. 30, no. 6, Feb. 1919, pp. 40-43, 2 figs. Rates of combustion; draft pressure; air requirements; diagram of water-tube boiler equipped with mechanical draft.

Feedwater Softening

Boiler Water Treatment. U. S. Fuel Administration, eng. bul. 3, 8 pp. Examples of economies effected by softening water.

Water Softeners, C. E. Stromeyer. Colliery Guardian, vol. 117, no. 3031, Jan. 31, 1919, pp. 248-249, 2 figs. Abstracted from memorandum of chief engineer to Manchester Steam Users' Assn.

Firebox

New Type of Firebox Construction. Boiler Maker, vol. 19, no. 2, Feb. 1919, pp. 33-37 and 61, 4 figs. Customary arch tubes are replaced by "thermic syphons" or tubular sections extending from lower part of throat sheet up to rear end of crown sheet; upper part of tubular section is extended in form of flat plates, spaced 4 in. apart up to crown sheet for nearly entire length of firebox.

Heat Losses

Fuel Economy in the Boiler House—I, John B. C. Kershaw. Chem. & Metallurgical Eng., vol. 20, no. 4, Feb. 15, 1919, pp. 176-178, 3 figs. Study of heat losses and their control.

High Steam Pressures

Use of Higher Steam Pressures and Temperatures in Power Plants, J. H. Shaw. Elec. Rev., vol. 74, no. 7, Feb. 15, 1919, pp. 252-256, 5 figs. Practical and theoretical considerations involved; their effect upon turbine efficiency, design and plant layout. Abstract of paper before the Am. Inst. of Elec. Engrs.

The Use of High-Pressure and High-Temperature Steam in Large Power Stations, J. H. Shaw. Jl. Instn. Elec. Engrs., vol. 57, no. 278, Jan. 1919, pp. 73-82 and (discussion) pp. 82-108, 5 figs. Discussion of economical aspect of question; quotes data of various stations and suggests a schedule showing coal consumption, cost of coal, and amount of capital that can be expended to absorb estimated saving.

Isolated Plant

Saving Coal in Steam Power Plants. U. S. Fuel Administration, eng. bul. 2, 8 pp., 4 figs. Isolated plant vs. central-station power; typical distribution of heat in medium-sized hand-fired plant, chief losses in boiler-plant operation.

Oil Elimination

Oil Elimination, Charles L. Hubbard. Nat. Engr., vol. 23, no. 2, Feb. 19, 1919, pp. 75-79, 16 figs. Discussion of various methods used to eliminate oil from exhaust steam and condensation and their principles of operation; exhaust steam separators; purpose of baffle plates and corrugations; steam filtration; purifying condensate.

Operation

Improving Factory Steam Plants, H. A. Wilcox. Power Plant Eng., vol. 23, no. 4, Feb. 15, 1919, pp. 184-187, 1 fig. Case IV. Putting old plant into condition to finish its years of service efficiently. Sixth article.

Outline of Factors Governing Economical Boiler Operation, Robert June. Elec. Rev., vol. 74, no. 7, Feb. 15, 1919, pp. 257-260, 2 figs. Combustion, loss due to excess air and losses in burning coal; accounted-for and unaccounted-for losses. Second article.

Power Plants

New Philadelphia Power Plant, Walter C. Edge. Nat. Engr., vol. 23, no. 2, Feb. 1919, pp. 53-57, 6 figs. Designed to eliminate three old plants and to provide ample heat for process work from exhaust steam of engines and auxiliaries.

Safety

Placing Valves in Unsafe Positions, V. R. Hughes. Power, vol. 49, no. 8, Feb. 25, 1919, pp. 266-268, 17 figs. Examples of safe and unsafe arrangements.

Service Records

Memoranda of Office Records, Allan W. Cuddeback. Can. Engr., vol. 36, no. 7, Feb. 13, 1919, pp. 217-218, 2 figs. Records of location of service pipes, valves, hydrants and distribution mains of Passaic Water Co.

Stokers

New Travelling Grate Stoker for Forced Draft. Power Plant Eng., vol. 23, no. 5, March 1, 1919, pp. 262-263, 3 figs. Illustrated description of the Harrington stoker.

Design and Construction of Mechanical Chain Grate Stokers, W. H. Grantham. Mech. World, vol. 64, nos. 1668 and 1669, Dec. 20 and 27, 1918, pp. 294 and 307, 7 figs. Laclide-Christie design. Sixth and seventh installments. (Concluded.)

Turbines

Reliable Performance of Large Turbines. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 147-148, 3 figs. Turbine generator of 35,000 kw. installed in Commonwealth Edison Co., Chicago.

Steam Turbine Operation, J. B. Wilson. Power Plant Eng., vol. 23, no. 5, Mar. 1, 1919, pp. 227-231, 5 figs. Points to be watched and conditions to be sought for best economy.

Waste Heat

The Utilization of Waste Heat from Open-Hearth Furnaces for the Generation of Steam, Thomas B. Mackenzie. Iron & Steel Can., vol. 2, no. 1, Feb. 1919, pp. 14-24, 3 figs. Data obtained from experiments with acid-lined furnaces or ordinary construction. Paper before Iron & Steel Inst.

See also MECHANICAL ENGINEERING, *Fuels and Firing (Wet Coal)*.

POWER TRANSMISSION

Mill Drive

Geared Versus Direct-Coupled Motors, R. W. Davis. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 138-139, 3 figs. Example of 2000-hp., 81-r.p.m., 6600-volt, 3-phase, 25-cycle motor built with direct-coupled tandem plate mill drive.

PRODUCER GAS

Blast Furnace

The Blast Furnace as a Gas Producer. Blast Furnace, vol. 7, no. 3, Mar. 1919, p. 127. Concerning German blast furnace practice. From Stahl und Eisen.

PUMPS

Water-Works Pumps

Economic Value of Electrically Driven Pumps for Small Water Works, D. D. Ewing. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 68-70. Illustrative examples. Figures are of pre-war type.

Electrically Driven Pumps in Small Waterworks, D. D. Ewing. Engineering and Contracting, vol. 51, no. 7, Feb. 12, 1919, pp. 170-171. Energy required by electrically driven pumps; power requirements; concrete illustration of motor-application principle; cost of changing to electrically driven pumps. From paper before Indiana Eng. Soc., 1919.

REFRACTORIES

Basic Refractories

Basic Refractories for the Open Hearth, J. Spotts McDowell and Raymond M. Howe. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 291-309, 7 figs. Report of laboratory tests. Low-line magnesite showed less tendency to slake, higher refractoriness and greater resistance to attack by firebrick and silica brick than high-lime magnesite; dolomitic materials highest in impurities and lowest in lime were most resistant to slaking; magnesites were more resistant than dolomites to slaking and to action of corrosive Fe_3P, Fe_2O_3, fireclay and silica.

Firebrick

How Slag Temperatures Affect Firebrick, Raymond M. Howe. Brick & Clay Rec., vol. 54, no. 2, Jan. 28, 1919, pp. 143-144. Results of tests indicating effects on life of brick. From Iron Trade Rev.

Great Britain

Refractories. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 19. Empire sources of supply; possibilities in manufacturing reforms.

See also MECHANICAL ENGINEERING, Furnaces (Kilns); METALLURGY, Blast Furnaces (Slag Action).

REFRIGERATION

Marine Refrigeration

Developments in Marine Refrigeration and Details of Brunswick Apparatus, W. O. Whitney. Jl. Am. Soc. Marine Draftsmen, vol. 6, no. 3, Oct. 1918, pp. 36-40, 6 figs. Features of the various types of refrigerating plants; discussion of their respective applicability.

Meat Industry

The Efficiency of the Frozen-Meat Industry, G. L. D. James. New Zealand Jl. Sci. & Technology, vol. 1, no. 6, Nov. 1918, pp. 341-345. Loss of dead weight in railing and droving, freezing, and transport.

RESEARCH

Gas Industry

The Place of Research in the Gas Industry, S. W. Parr. Gas Age, vol. 43, no. 3, Feb. 1, 1919, pp. 135-136. Points out fields of investigation. From paper before Western Soc. Engrs.

Great Britain

Research Progress. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 31. Work done by Dept. of Sci. & Indus. Research, Great Britain.

United States

American Engineering Research, W. R. Whitney. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 2, Feb. 1919, pp. 115-127. Calls attention to our national condition in relation to engineering research and expresses convenience of crystallizing research work into an acceptable form.

Research in America After the War, R. A. Millikan. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 2, Feb. 1919, pp. 129-140. Suggestions in regard to concerted action between similar committees of the various scientific societies.

STANDARDS AND STANDARDIZATION

Brass and Bronze Foundries

Standards for Brass and Bronze Foundries and Metal Finishing Processes, Lillian Eskine. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 263-275. Study of approved practices and equipment to safeguard health of workers.

German Machinery

Standardization in German Machine Building (Vereinheitlichung in deutchen Maschinenbau). Zeitschrift der Deutscher Gesellschaft fuer Mechanik und Optik, nos. 1 and 2, Jan. 15, 1918, pp. 1-6. Standardization to meet competition after the war. This installment contains the first five standard tables intended to be followed by "German Machine Industrie," including sizes of drawings, German standardization, etc.; also list of members throughout Germany engaged in this work. Effective since Feb. 15, 1918. From Zeitschrift ver d. Ing., vol. 61, p. 985, 1917.

Lengths

Industrial Length Standards (Les calibres industriels de longueur), Ch.-Ed. Guillaume. Bulletin de la Société Française des Electriciens, vol. 8, no. 75, Dec. 1918, pp. 383-400, 5 figs. Development of present principles of gaging; comparison of various standards; gaging machines of the Société Génevoise. Writer believes advisability of ascertaining from manufacturers their experience with the various metals used in manufacture of gages and deciding from study of reports on a standard which will satisfy all requirements.

Motor-Car Parts

Standards Committee Acts on Division Reports. Automotive Industries, vol. 40, no. 6, Feb. 6, 1919, pp. 307-311, 8 figs. Ball-bearing, electrical, engine, spring, tire and rim S.A.E. recommended standards.

Steel

British Adopt Twenty Standard Steel Specifications. Automotive Industries, vol. 40, no. 8, Feb. 20, 1919, pp. 418-419. Gives chemical and physical properties, together with definitions of terms used.

See also MECHANICAL ENGINEERING, Pipe (Standards); RAILROAD ENGINEERING, Rolling Stock (Standards for Freight Equipment); ELECTRICAL ENGINEERING, Generators and Motors (Standardization of Motors), Standards; ORGANIZATION AND MANAGEMENT, Factory Management (Standardization of Methods).

STEAM ENGINEERING

Boilers

Water Circulation in Boilers, A. D. Williams. Power, vol. 49, no. 8, Feb. 25, 1919, pp. 285-286. Notes on water circulation in water-tube boilers. Description of simple experiments by which observer can obtain an idea of flow of steam in tubes of varying pitch.

The Principles of Heat Absorption, Robert June. Brick & Clay Rec., vol. 54, no. 2, Jan. 28, 1919, pp. 133-136, 6 figs. Importance of maintaining clean surfaces in boiler.

Turbines

Notes on Large Steam Turbine Design, J. F. Johnson. Elec. Jl., vol. 16, no. 1, Jan. 1919, pp. 33-38, 4 figs. Operating records; load capacities; graph of relative steam consumption of large-capacity turbines; principles of turbine design. Paper before Phila. Section, Am. Soc. Mech. Engrs.

The Assembly and Adjustment of Steam Turbines, J. Humphrey. Machinery, vol. 13, no. 331, Jan. 30, 1919, pp. 486-492, 14 figs. Turbines considered are those working on Parsons principle and having a large number of fixed and moving blades, caulked into casing and on periphery of rotor.

High-Power Steam Turbines (Les turbines à vapeur de grandes puissances), Jean Guerner. Revue Générale de l'Electricité, vol. 5, no. 6, Feb. 8, 1919, pp. 227-230, 3 figs. Development of steam turbines, with reference to American models; economical comparison of the various types, from data obtained in American practice.

WELDING

Acetylene Welding

A Missing Link in Welding Equipment, Arthur W. Dohmen. Jl. Acetylene Welding, vol. 2, no. 8, Feb. 1919, pp. 388 and 392-393, 4 figs. Instrument which indicates flow of gases being used by welder.

Improvements in Guides for Oxy-Acetylene Blowpipes. Acetylene & Welding Jl., vol. 15, no. 183, Dec. 1918, p. 226, 3 figs. Guide consists of rotating plate having eccentrically mounted tube; supporting base for plate is provided with ball race.

Oxy-Acetylene Welding and Cutting. Eng. & Min. Jl., vol. 107, no. 6, Feb. 8, 1919, pp. 268-269. Abstract of bul. 11 of Federal Board for Vocational Education.

Oxy-Acetylene Welding Problems, W. L. Bean. Ry. Mech. Eng., vol. 93, no. 2, Feb. 1919, pp. 97-100, 3 figs. Discussion of flame structure and methods of handling; careful training of operators necessary. From paper before New England Ry. Club.

Oxy-Acetylene Welding. Power Plant Eng., vol. 23, no. 5, Mar. 1, 1919, pp. 244-246, 2 figs. Hints for beginners and pointers on power plant repair jobs. Second article.

Boiler Welding

Boiler Welding, P. F. Willis. Jl. Acetylene Welding, vol. 2, no. 8, Feb. 1919, pp. 393-398, 29 figs. Welding of a half side sheet in a locomotive firebox; welding of simple crack; welding half door sheets. From book on Oxy-Acetylene Welding and Cutting. To be continued.

Cast Iron

Welding Cracked Cast Iron Radiators, David Baxter. Metal Worker, vol. 91, no. 3, Jan. 17, 1919, pp. 83-85, 3 figs. Particulars of work and skill required for job. From Jl. Acetylene Welding.

Covered Electrode Welding

The Covered Electrode Process, E. G. Rigby. Jl. Engrs. Club Phila., vol. 35-10, no. 167, Oct. 1918, pp. 472-482, 6 figs. Its adoption in English shipyards; equipment; conditions required for good welding; its application to ship's deck structures, bulkhead structures, etc. Fourth discussion under auspices of U. S. Shipping Board Emergency Fleet Corporation.

Electric Welding

Electric Welding—A New Industry, H. A. Hornor. Jl. Engrs. Club, Phila., vol. 35-12, no. 169, Dec. 1918, pp. 537-543, 12 figs., and Elecn., vol. 82, no. 2122, Feb. 17, 1919, pp. 96-97. Present status; review of suggestions offered to develop scientific system of testing; methods of electric welding.

Electric Welding Practice, Comfort A. Adams. Jl. Engrs. Club Phila., vol. 35-12, no. 169, Dec. 1918, pp. 531-536, 7 figs. Testing; research; training; ship design and costs; shipyards committee. Seventh discussion under auspices of U. S. Shipping Board, Emergency Fleet Corporation.

Fusion in Arc Welding

Fusion in Arc Welding, O. H. Escholz. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 3, Mar. 1919, pp. 319-327, 16 figs. Characteristics of metallic electrode arc welding, and effect of arc length, welding procedure, electrode material, arc current and electrode diameter upon these characteristics.

Inspection

Inspection of Metallic-Electrode Arc-Welds, O. S. Escholz. Min. & Sci. Press, vol. 118, no. 8, Feb. 22, 1919, p. 26, 7 figs. Methods for indicating fusion, slag content, porosity, and crystal structure.

Mild Steel

Welding Mild Steel, H. M. Hobart. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 517-561, 17 figs. Investigation undertaken by welding research sub-committee of welding committee of the Emergency Fleet Corporation. Object was to extend use of welding in construction of merchant ships and to provide basis for obtaining the best economy and efficiency in employing welding in place of riveting in construction of hulls.

Pressure in Weld

Difficulties Encountered in Welding Steel, B. K. Smith. Boiler Maker, vol. 19, no. 2, Feb. 1919, pp. 39-40. Pressure of iron oxide in the weld; problems of expansion and contraction.

Pressure Vessels

Oxy-Acetylene Welding as Applied to Pressure Vessels. Acetylene & Welding Jl., vol. 15, no. 183, Dec. 1918, pp. 220-221, 1 fig. Example of welded gas containers. From Revue de la Soudure Autogène.

Radiograph

Radiograph Proves Successful "Jack-of-All-Operations." Jl. Acetylene Welding, vol. 2, no. 8, Feb. 1919, pp. 385-387, 6 figs. Account of exhibition of Davis-Bournonville apparatus.

Ruptures in Welds

Path of Rupture in Steel Fusion Welds, S. W. Miller. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 311-338, 82 figs. Report of research under joint auspices of Nat. Research Council and Emergency Fleet Corporation.

Thermit Welding

Modern Welding and Cutting, Ethan Viall. Am. Mach., vol. 50, nos. 7, 8 and 9, Feb. 13, 20 and 27, 1919, pp. 283-291, 20 figs., pp. 341-346, 10 figs., pp. 389-394, 16 figs. Thermit welding of crankshafts, mill pinions, etc. Second, third and fourth articles.

See also MARINE ENGINEERING, Yards (Welding).

WOOD AND TIMBER

Veneer Manufacture

The Manufacture of Veneer and Plywood, B. C. Boulton. Aerial Age, vol. 8, no. 25, Mar. 3, 1919, pp. 1240-1241, 1272 and 1285, 7 figs. Methods of cutting preparation of logs for sawing and slicing; slicer cutting; veneer sawing and drying.

VARIA

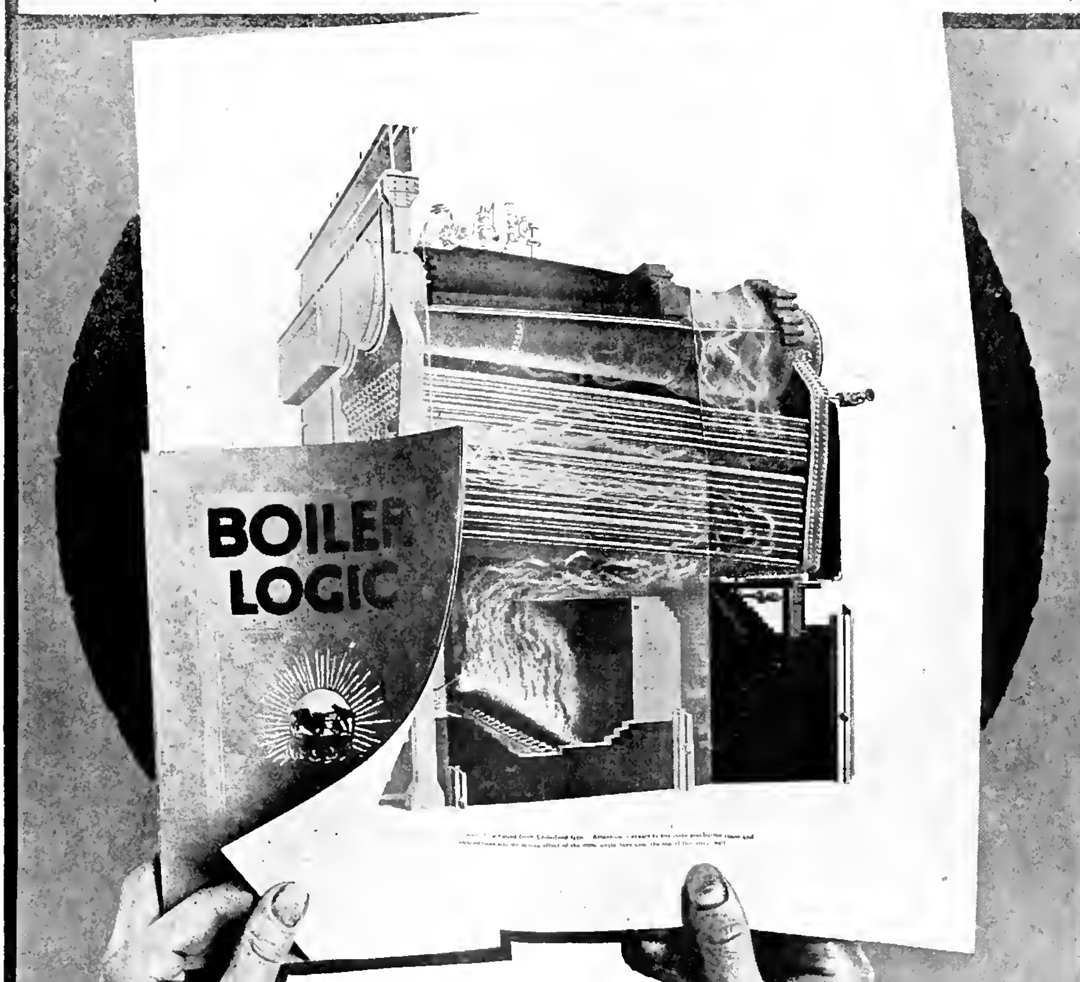
Engineering Societies

Address at the Annual Meeting, Arthur N. Talbot. Proc. Am. Soc. Civil Engrs., Papers & Discussions, vol. 45, no. 2, Feb. 1919, pp. 29-51. Review of activities of the year and discussion of outlook of Society.

Engineer's Part in Reconstruction

The Engineer's Part in After-the-War Problems, F. H. Newell. Sci. Monthly, vol. 8, no. 3, Mar. 1919, pp. 239-246. How the engineer and organizations of engineers, both indivi-

"BOILER LOGIC,"
OUR BOILER TREATISE, HAS BEEN REPRINTED
Contains colored frontispiece shown below.



Will you need a new boiler this year? Next year? Two years hence?

If so, begin "studying up" by reading the Heine authority BOILER LOGIC. It is a very comprehensive treatise on boilers, boiler theory, boiler practice—86 pages.

Every man responsible for economic steam production should *get, study,* and KEEP a copy.

HEINE SAFETY BOILER CO.

dually and collectively, can perform their largest service.

Hotels

Mechanical Equipment of a Modern Hotel. Power, vol. 49, no. 7, Feb. 18, 1919, pp. 230-233, 9 figs. First of series describing mechanical equipment of Hotel Pennsylvania, New York City.

Latin-American Engineering Conditions

Relation Between Engineering and Agriculture in Latin America. A. M. Shaw. La. Planter & Sugar Mfr., vol. 62, no. 7, Feb. 15, 1919, pp. 106-107. Present conditions in Latin America; opportunities these nations offer.

Licensing of Engineers

The Registration of Professional Engineers. Jl. Electricity, vol. 42, no. 3, Feb. 1, 1919, pp. 125-127. Act for licensing of engineers, prepared by San Francisco local sections of engineering societies.

Nomenclature, Scientific

Note on the Linguistic Nomenclature of Scientific Writers, Albert Campbell. Proc. Phys. Soc. London, vol. 31, part 2, Feb. 15, 1919, pp. 80-81 and (discussion) pp. 81-83. Comments on anglicizing terms from Latin and Greek introduced in the language. Suggests "pulsance" as name for $2\pi \times$ frequency.

State's Part in Industries

Engineers and the State. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 8. Opinions concerning part Government should take in problems confronting industry.

Electrical Engineering

ELECTROCHEMISTRY

Potentials, Signs

The Sign of Potentials, Oliver P. Watts. Brass World, vol. 15, no. 2, Feb. 1919, pp. 37-39, 1 fig. Argues that sign adopted for potential of a metal is of importance to electrochemistry and urges continuing established use of plus sign for potential of zinc.

ELECTROPHYSICS

Air Films, Dielectric Strength of

The Dielectric Strength of Air Films Entrapped in Solid Insulation and a Practical Application of the Problem for Alternator Coils and Cables, F. Dubsky. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 2, Feb. 1919, pp. 141-161, 7 figs. It was found from experiments that the dielectric strength of air films between insulations was practically the same as the dielectric strength of air films between conductors. Specific examples are given illustrating application of data to design of armature coils and cables.

Amplification of Currents

Amplification of the Photoelectric Current by Means of the Audion. Carl Eli Pike. Phys. Rev., vol. 13, no. 2, Feb. 1919, pp. 102-108, 8 figs. Experiments, it is reported, have demonstrated that photoelectric currents can be amplified by means of the audion from 1600 to 5000 times.

Current, Flow of

Propagation of the Current in an Electric Line (Propagation du courant dans une ligne), J. B. Pomey. Revue Générale de l'Electricité, vol. 5, no. 6, Feb. 8, 1919, pp. 204-209. Demonstration of Heaviside formula and derivation of a relation to cover case when variable electromotive force starts from a given condition of motion.

Electric Circuit, General Equation of

The General Equations of the Electric Circuit—III. Charles P. Steinmetz. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 3, Mar. 1919, pp. 249-318, 11 figs. Variation of constants r, L, C, and g, and its effects. Equations of line constants as function of equivalent frequency are derived, and applications thereof made to various problems.

Electromagnetic Fields

On the Flow of Energy in the Electromagnetic Field Surrounding a Perfectly Reflecting Cylinder, T. K. Chinmayan. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919, pp. 9-33, 8 figs. Positions of maxima and minima of illumination and visibility of fringes when plane light waves are grazingly incident in a direction at right angles to axis of cylinder.

Electromagnetic Phenomena, Mechanical Representation of

Mechanical Representations of Electromagnetic Phenomena (Représentations mécaniques des phénomènes électromagnétiques), Artur Korn. Revue Générale de l'Electricité, vol. 5, no. 4, Jan. 25, 1919, pp. 150-151. Considerations on a mechanical representation of an electron, the electric current and a magnet. From Electrotechnische Zeitschrift, vol. 39, Sept. 12 and 19, 1918, pp. 363-375.

Electromagnetic Oscillations

Productions of Electromagnetic Oscillations (Production d'oscillations électromagnétiques), Ricardo Arnó. Industrie Electrique, vol. 27, no. 635, Dec. 10, 1918, pp. 443-444. Produced directly by alternating currents used in industry. Brief abstract of communication to Institute Lombard des Sciences et des Lettres.

Grid Currents in Vacuum Tubes

Note on the Effects of Grid Currents in Three-Electrode Ionic Tubes, E. V. Appleton. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919, pp. 129-134, 2 figs. Conductance of grid circuit inside tube is treated as high-resistance leak across condenser of oscillatory circuit connected to grid and filament; effect of this leak in amplifying and oscilation circuits is investigated quantitatively.

Insulation, Electrical Stresses in

Ionization of Occluded Gases in High-Tension Insulation, G. B. Shanklin and J. J. Matson. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 2, Feb. 1919, pp. 163-210, 21 figs. Determination of safe working stress from measurements of stress at which ionization starts in different types of built-up insulation, such as used in cables and coils. Paper brings out importance of reducing gas spaces to minimum size and using materials of lowest possible permittivity, since the higher the permittivity the greater the stress on the gas spaces.

Insulators, Rupture of

Mechanism of the Rupture of Electric Insulators (Le mecanism de la rupture des isolants électriques). Génie Civil, vol. 74, no. 5, Feb. 1, 1919, pp. 92-93, 3 figs. Factors determining rupture; effect with alternating currents.

Iron Losses at Radio Frequencies

Note on Losses in Sheet Iron at Radio Frequencies, Marius Latour. Proc. Inst. Radio Engrs., vol. 7, no. 1, pp. 60-71, 1 fig. Calculation of power dissipated separately by Foucault currents and by hysteresis in a sheet of iron, assuming constant angle of lag between magnetic induction in sheet and magnetizing field producing it; thickness of iron sheet which will make total power a minimum; angle of lag between voltage and current in circuit of inductance coil.

Hysteresis and Eddy-Current Losses in Iron at Radio Frequencies, Christian Nusbaum. Proc. Inst. Radio Engrs., vol. 7, no. 1, Feb. 1919, pp. 15-26, 8 figs. Review of literature on heat losses per cycle at various frequencies; comparison calorimetric method whereby losses in soft-iron-wire core of a toroid are measured against similarly wound toroid without iron core.

Magnetic Flux Density

The Natural Frequency of an Electric Circuit Having an Iron Magnetic Circuit, H. G. Cordes. Proc. Inst. Radio Engrs., vol. 7, no. 1, Feb. 1919, pp. 73-82, 2 figs. Following Steinmetz procedure, magnetic flux density in laminated iron core with a.c. current excitation is found; then expressions and tables for determining natural frequency of circuits containing iron-core inductances are given; results obtained are numerically illustrated.

Magnetism, Kinetic Theory of

On a Kinetic Theory of Magnetism in General, Kōtarō Honda and Junzo Okubo. Phys. Rev., vol. 13, no. 1, Jan. 1919, pp. 6-26, 4 figs. Modifications in Langevin's theories of paramagnetic and diamagnetic substances in order to account for observed facts.

Resistance Measurements, Radio-Frequency

The Measurement of Radio Frequency Resistance, Phase Difference, and Decrement, J. H. Dellinger. Proc. Inst. Radio Engrs., vol. 7, no. 1, Feb. 1919, pp. 27-59, 9 figs. Relations between resistance, phase difference, sharpness of resonance, and decrement; derivation and classification of methods of measurement. Methods are comprised under resistance-variation and reactance-variation. Special direct-reading methods of measuring reactance.

Short-Circuit Current Calculation

Calculation of Short-Circuit Currents in Alternating-Current Systems, W. W. Lewis. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 140-145, 8 figs. The author describes the use of a calculating table for solving complicated problems in the determination of short-circuit currents in large power networks.

Sinusoidal Current, Action of

Electrical State of a Line Carrying a Sinusoidal Current (Etat permanente sur une ligne parcourue par un courant sinusoïdal), M. E. Brylinski. Bulletin de la Société Française des Electriciens, vol. 8, no. 75, Dec. 1918, pp. 401-420. Formulæ for electrical quantities determined for various cases.

Steel Conductors

Resistance and Reactance of Commercial Steel Conductors, H. B. Dwight. Elec. Jl., vol. 16, no. 1, Jan. 1919, pp. 25-27, 15 figs. Curves showing amperes per wire against ohms per mile for different sizes; graphs drawn from results of tests.

Transient Oscillations

Theory of the Transient Oscillations of Electrical Networks and Transmission Systems, John R. Carson. Proc. Inst. Elec. Engrs., vol. 38, no. 3, Mar. 1919, pp. 407-489, 22 figs. Theoretical study with view to developing methods of calculation directly applicable to engineering problems. A formula is derived which expresses current in electric network due to suddenly applied e.m.f. in terms of applied e.m.f. as time function and a characteristic function of constants and connections of system.

See also ELECTRICAL ENGINEERING, Telegraphy and Telephony (Vacuum Tubes).

FURNACES

Manufacture

Furnace Company Completes New Plant. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 152-153, 2 figs. Features of electric furnace manufacturing plant.

Plant of the Electric Furnace Co. Brass World, vol. 15, no. 2, Feb. 1919, pp. 61-63, 10 figs. Plant manufactures Baily furnaces for electrical heat-treating and annealing of steel, and melting of nonferrous metals.

Rennerfelt Furnace Operation

Melting Silver, Nickel and Bronze Alloys by Electricity. Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, pp. 323-324. Results at Phila. mint with 1000-lb. Rennerfelt electric furnace.

Resistor-Type Experimental Furnace

Experimenting with the Electric Furnace. Wirt S. Scott. Jl. Electricity, vol. 42, no. 4, Feb. 15, 1919, pp. 173-174. Experimental work on resistor-type furnaces for forging.

Steel Furnaces

Electric Furnaces as Applied to Steel Making, Henry Lawrence Hess. Mech. Eng., vol. 41, no. 3, Mar. 1919, pp. 245-248, 5 figs. Methods of producing electric steel; Héroult type of furnace; cold method of producing electric steel; method of pouring, rolling and other furnace operations practiced in plant operating two 6-ton and four 7-ton Héroult furnaces.

See also METALLURGY, Iron and Steel (Electric Smelting).

GENERATING STATIONS

Canada

Statistical Analysis of the Central Electrical Station Situation of Canada. Elec. News, vol. 28, no. 3, Feb. 1, 1919, pp. 26-30, 7 figs. Synopsis of data prepared by Dominion Water Power Branch of Dept. of Interior, in coöperation with Dominion Bur. of Statistics of Dept. of Trade & Commerce.

Diesel Engines

Electric Generation by Diesel Engine, E. J. Richards. Jl. Electricity, vol. 42, no. 4, Feb. 15, 1919, pp. 167-169, 5 figs. Results obtained at large copper mine.

Hydroelectric Plants

Michigan's Largest Hydroelectric Development. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 21-24, 6 figs. Layout; coördination of turbines installed to water flow; equipment of 140,000-volt transmission line.

Single-Phase Current Generation

The Supply of Single-Phase Power from Three-Phase Systems, Miles Walker, Jl. Instn. Elec. Engrs., vol. 57, no. 278, Jan. 1919, pp. 109-139 and (discussion) pp. 139-148, 49 figs. Methods of obtaining single-phase power, particularly (1) by taking of single-phase current direct from one of phases of a three-phase supply system and use of balancer for balancing phases, and (2) by a rotating balancing transformer which absorbs balanced three-phase power in one winding and supplies a single-phase load from an independent winding. A calculation of a balancing transformer for feeding a 400-kw. electric furnace is worked out; figures obtained in tests of machine at no load and at full load are given.

GENERATORS AND MOTORS

Brushes

Application of Brushes to Electrical Machinery, Warren C. Kal, Power, vol. 49, nos. 7 and 8, Feb. 18 and 25, 1919, pp. 241-243 and 276-278, 9 figs. Feb. 18: Various types of brushes used on electrical machinery, their composition, method of manufacture and field of application. Feb. 25: Discussion of effect of conditions of service upon selection of carbon brushes.

Cooling of Motors

Cooling of Electric Motors, with Special Reference to Totally-Enclosed Machines. P. A. Mossay. Tran. Instn. Min. Engrs., vol. 56, part 2, Dec. 1918, pp. 103-115 and (discussion)pp. 115-117, 13 figs. Writer's experience and suggestions in regard to present systems of ventilating motors.

Demand Factors of Motors

Determination of Demand Factors to Save Copper, Henry C. Horstmann and Victor H. Tousley. Elec. World, vol. 73, no. 7, Feb. 15, 1919, pp. 308-310, 3 figs. Methods by which electrical inspectors can more accurately gauge in advance probable demand factors of different types of motor installations.

Induction Motors, Speed Control of

Speed Control of Induction Motors on Cranes and Hoists by means of Solenoid Load Brakes, R. H. McLain and H. H. Vernon. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 117-125, 9 figs. Article covers different applications of solenoid brakes and gives a detailed description of a solenoid load brake.

Mechanically Connected Motors

The Operation of Mechanically-Connected Direct-Current Motors Permanently in Series or Permanently in Parallel, H. F. Stratton. Popular Engr., vol. 11, no. 2, Feb. 1919, pp. 10-13, 8 figs. Reasons why preference is given to several mechanically connected motors in preference to a single large motor. (To be continued.)

Standardization of Motors

Advantages of Uniform Motor Design. Rotary Apparatus. Elec. Power Club, bul. 6010, Jan. 2, 1919, 6 pp. Views of manufacturers and users concerning standardization of electric motors.

Synchronous Motors, Starting

Starting Synchronous Motors, E. E. George. Elec. Wld., vol. 73, no. 9, March 1, 1919, pp. 429-430. How to avoid excessive currents and mechanical strains in synchronous motors started as induction machines.

LIGHTING AND LAMP MANUFACTURE

Municipal Lighting

A Study in Municipal Electric Lighting. Stone & Webster Jl., vol. 24, no. 2, Feb. 1919, pp. 104-112. Comparative data showing results of municipal electric lighting in Massachusetts.

Pocket Lamps

Pocket Electric Lamps (Les lampes électriques de poche), L. Lindet. Bulletin de la Société d'Encouragement, vol. 130, no. 6, Nov.-Dec. 1918, pp. 398-399. Development of industry in France; details of manufacture.

Theatres

Electric Lighting of Theatres (L'éclairage électrique au théâtre), J. Reyval. Revue Générale de l'Electricité, vol. 5, no. 4, Jan. 25, 1919, pp. 133-145, 11 figs. Brief survey of progress in artificial lighting of theatres; description of electric installation of the Théâtre National de la Comédie Française, Paris.

See also RAILROAD ENGINEERING, Safety and Signaling Systems (Signal Lamps, Focusing).

MEASUREMENTS AND TESTS

Kenotron

Measurement of the Crest Values of alternating Voltage by the Kenotron, Condenser, and Voltmeter, J. R. Craighead. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 104-109, 8 figs. Arrangement described embodies in one instrument a combination of qualities said not to be possessed by previous devices for the purpose. The theory and construction of the crest meter is described, test of its accuracy recorded and its advantages and limitations set forth.

POWER APPLICATIONS

California Campaign

California Coöperative Campaign Progress. Jl. Electricity, vol 42, no. 3, Feb. 1, 1919, pp. 108-110. Summary of accomplishments in 1918. Object of campaign is better electric service to public.

Electrometallurgical Industries

Electrometallurgical Industries in the Scandinavian Countries (Les industries électrométallurgiques dans les pays Scandinaves). Journal du Four Electrique, vol 28, no. 3, Feb. 1, 1919, pp 17-19. Statistical figures and notes on various projects.

Flour Mills

Electrical Equipment of New Pacific Coast Flour Mill. Elec. Rev., vol. 74, no. 8, Feb. 22, 1919, pp. 295-296, 5 figs. Mill at Pasco, Wash., is completely equipped electrically; labor-saving methods promote marked economy.

Heating

Electric Heating as a Profitable Load, Barry Dibble. Jl. Electricity, vol. 42, no. 3, Feb. 1, 1919, pp. 102-105, 2 figs. Data on cost and revenue of electric heating on Minidoka project, Idaho.

Laboratories

Electrically Equipped Laboratories, C. B. Merrick. Jl. Electricity, vol. 42, no. 4, Feb. 15, 1919, pp. 153-154, 2 figs. Installation at parasitology laboratories of Cal. State Board of Health.

Office Building

Electricity in a Large Office Building. Jl. Electricity, vol. 42, no. 4, Feb. 15, 1919, pp. 150-151, 3 figs. General description of electric equipment in Southern Pacific building, San Francisco.

Potteries

Electricity in the Ceramic Arts, J. P. Alexander. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 113-116, 4 figs. Describes various processes employed in the pottery industry and the service afforded by electricity in this field.

Shipbuilding

Electricity in the Shipbuilding and Shipping Industries. Shipbuilding & Shipping Rec., vol. 13, no. 1, Jan. 2, 1919, pp. 13-14. Concerning efficient development in utilization of power as means to face international competition.

Signs

Portland Sign Ordinance . Jl. Electricity, vol. 42, no. 3, Feb. 1, 1919, pp. 114-115. Regulations in Portland and Oregon.

See also MINING ENGINEERING, Minor Industrial Materials (Electric Power); MECHANICAL ENGINEERING, Heating and Ventilation (Electricity).

POWER GENERATION

Hydroelectric Plants

See Power Generation, MECHANICAL ENGINEERING.

STANDARDS

Fundamental Units, Definitions of

International Electrotechnic Commission (La comision electrotécnica internacional), Germán Niebuhr. Boletín de la Asociacion Argentina de Electro-Técnicos, vol. 4, no. 9, Sept. 1918, pp. 807-815, 2 figs. Definitions adopted for the fundamental units. Continuation of serial.)

Standardization

Standardization of Edison Lamp Bases and Sockets (Projet d'unification des filetages des culots et supports de lampes à vis Edison), C. Zetter. Bulletin de la Société d'Encourage-

TELEGRAPHY AND TELEPHONY

Amateur Radio

Amateur Radiotelegraphy of the Future, Alfred N. Goldsmith. Wireless Age, vol. 6, no. 5, Feb. 1919, pp. 11-13. Advocates operating all amateur radio stations of the future on sustained waves between 100 and 300 meters.

The Fire Underwriters' Rules Applied to Amateur Stations. Wireless Age, vol. 6, no. 6, Mar. 1919, pp. 32-33, 2 figs. Advisability of modifying installation to conform to Underwriters' rules and method of doing so.

Automatic Telephone, Western Electric

The Western Electric Company's Automatic Telephone System, B. O. Anson. Instn. Post Office Elec. Engrs., paper no. 72, pp. 1-47 and (discussion) pp. 48-61, 23 figs. Operation, details of principal apparatus used, schematic connections of various line exchanges, and records of service.

Baudot Quadruplex System

Paris-London Quadruplex Baudot Communication (Communication Baudot quadruple Paris-Londres), M. Mercy. Annales des Postes, Télégraphes et Téléphones, vol. 7, no. 4, Dec. 1918, pp. 623-624. Condensation is reported to have been overcome in Anglo-French cable by interpolation of differential transmission between cable and aerial line in France. Device used described in Annales, Mar. 1917, p. 144

British Colonies

The Telegraph and the Telephone in the British Colonies (Le télégraphe et le téléphone dans les Colonies britanniques). Journal Télégraphique, vol. 43, no. 1, Jan. 25, 1919, pp. 3-6. Australia and New Zealand. (Concluded.)

Ceylon

Telegraphs and Telephones in Ceylon in 1917 (Les télégraphes et les téléphones en Ceylon en 1917). Journal Télégraphique, vol. 43, no. 1, Jan. 25, 1919, pp. 13-14. Constructions and revenues. From report of Postmaster General.

French Colonies

Wireless Telegraphy in the French Colonies (La télégraphie sans fil dans les colonies françaises). Revue Générale de l'Electricité, vol. 5, no. 6, Feb. 8, 1919, pp. 233-234. Present conditions; particulars of the Messimy project. From Economiste française, Jan. 11, 1919.

Government Ownership

Both Sides of the Government Ownership Question. Wireless Age, vol. 6, no. 6, Mar. 1919, pp. 11-21 and 46, 13 figs. Summary of opposing testimony given in congressional hearing on Alexander bill for Government ownership of wireless.

Interference Prevention

General Rules Followed in the United States for Protecting Telephone Lines Against Three-Phase Lines (Règles générales suivis aux Etats-Unis pour protéger les lignes téléphoniques contre les lignes triphasées), M. Valensi. Annales des Postes, Télégraphes et Téléphones, vol. 7, no. 4, Dec. 1918, pp. 526-607, 38 figs. Prepared from information obtained in conferences of writer with engineers of Am. Telephone & Telegraph Co. and his perusal of Proc. Am. Inst. Elec. Engrs., notably Interference as a Practical Problem by A. H. Griswold and R. W. Mastick, and The Design and Transposition for Parallel Power and Telephone Circuits by H. S. Osborne.

Lloyd's Semaphore, Radio Telegraphy

Wireless Telegraphy and the Safety of Navigation (La télégraphie sans fil et la sécurité de la navigation maritime). Journal Télégraphique, vol. 43, no. 1, Jan. 25, 1919, pp. 6-10. Lloyd's semaphore plan proposed to the Paris International Conference. (To be continued.)

Mercury-Vapor Rectifiers

Mercury Vapor Rectifiers (Les redresseurs à vapeur de mercure). Revue Générale de l'Electricité, vol. 5, no. 4, Jan. 25, 1919, pp. 146-149, 8 figs. Scheme of connections, efficiency curves and oscillograms of voltages and currents. From Schweizerische Bauzeitung, vol. 72, Sept. 28, 1918, pp. 117-120, 13 figs.

Molybdenite Rectifiers

Photoelectric Sensitivity vs. Current Rectification in Molybdenite, W. W. Coblentz and Louise S. McDowell. Phys. Rev., vol. 13, no. 2, Feb. 1919, pp. 154-155. Tests are said to have shown that low-resistance, photoelectrically-insensitive samples of molybdenite are more efficient rectifiers than high-resistance, light-sensitive specimens.

Multiplex Transmission

Multiplex Telegraphy and Telephony. Wireless Age, vol. 6, no. 6, Mar. 1919, pp. 22-23, 4 figs. Concerning use of radio frequency currents.

Multiplex Telephony and Telegraphy, Frank B. Jewett. Telegraph & Telephone Age, vol. 37, no. 2, Jan. 16, 1919, pp. 45-47, 4 figs. Development and possibilities.

Naval Radio Stations

A Brief Technical Description of the New San Diego, Pearl Harbor, and Cavite High Power Naval Radio Stations, Leonard F. Fuller. Proc. Inst. Radio Engrs., vol. 7, no. 1, Feb. 1919, pp. 11-13.

Radio Progress During War

Radio Development During the War, Nugent H. Slaughter. Elec. World, vol. 73, no. 7, Feb. 15, 1919, pp. 311-315, 4 figs. Problems with which Signal Corps was confronted when the United States first engaged in conflict; how it placed radio-apparatus production on quantity basis; nature of improvements made.

Resonance Measurements

Resonance Measurements in Radiotelegraphy with the Oscillating Audion. Proc. Inst. Radio Engrs., vol. 7, no. 1, Feb. 1919, pp. 9-10. The telephone click in an oscillating audion circuit when a coupled circuit is brought into tune with it is utilized to measure quickly and accurately antenna capacity, wave length of distant stations, capacities, inductances and wave lengths.

Rouzet Transmitting System

Rouzet Transmitting System for Increasing Spark Frequencies. Wireless Age, vol. 6, no. 5, Feb. 1919, p. 20, 4 figs. Wiring diagram.

Simultaneous Telegraphy and Telephony

The Van Rysselberghe System of Simultaneous Telegraphy and Telephony, the Marshall Electrical Condenser, Etc., Wm. Maver, Jr. Telegraph & Telephone Age, vol. 37, nos. 1 and 4, Jan. 1 and Feb. 16, 1919, pp. 21-23 and 95-97. (Concluded from Sept. 16, 1918.)

Telegraph Lines, Protection Against Lightning

Protection Against Lightning and High Tension Circuits. Telegraph & Telephone Age, vol. 37, no. 2, Jan. 16, 1919, pp. 42-44. Summary of experience of railroad telegraph de-

partments. Presented at convention of Assn. Ry. Telegraph Superintendents. (Concluded.)

Telephone Circuits

Telephone Circuits With Zero Mutual Induction. William W. Crawford. Proc. Am. Inst., Elec. Engrs., vol. 38, no. 3, Mar. 1919, pp. 377-405, 11 figs. Deals with reduction of inductive interference in telephone circuits. Several forms of construction involving various relative positions of two or more circuits, in which mutual inductance is zero, and mutual capacitance unbalance approximately zero, are discussed.

Telephone Relays

Telephone Relays Used by the French Administration (Les relais téléphoniques employés par l'Administration française). Revue Générale de l'Electricité, vol. 5, no. 4, Jan. 25, 1919, pp. 151-152, 4 figs. Apparatus deviced by Latour. From Annales des Postes, Télégraphes et Téléphones, vol. 7, Sept. 1918, p. 403, 4 figs.

Telephones, Automatic

Automatic Telephone Systems. J. N. Wallace. New Zealand Jl. Sci. & Technology, vol. 1, no. 6, Nov. 1918, pp. 331-340, 6 figs. Development and operation.

Telephony, Radio

Magnetic Modulating System for Wireless Telephony. Wireless Age, vol. 6, no. 5, Feb. 1919, pp. 20-21, 3 figs. Modulation effected by subjecting magnetic core to relatively weak and rapidly alternating cross magnetization.

Radio Telephony. E. B. Craft and E. H. Colpitts. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 3, Mar. 1919, pp. 337-375, 43 figs. Development of systems of generation, modulation, transmission and reception of radio telephone systems; work of producing radio telephone and allied apparatus for Army and Navy in late war.

Tone Frequencies

The Production of Tone Frequencies. Wireless Age, vol. 16, no. 5, Feb. 1919, pp. 18-20, 6 figs. Oscar Roos methods of operating wireless system over wide range of tone frequencies.

Vacuum Tubes

War-Time Development of Vacuum Tubes, Ralph Brown. Elec. World, vol. 73, no. 8, Feb. 22, 1919, pp. 358-363, 9 figs. Most important advance in radio engineering; three stages; determining desirable characteristics; designing tubes having these characteristics and capable of being produced in quantities; specifications and test methods.

Wave-Length Standardization

The Standardization of the Wave Lengths of Electro-Magnetic Waves for Radio Engineering and the Calibration of Wave Meter (In Japanese). K. Nishizaki. Denki Gakkwai Zasshi, no. 366, Jan. 10, 1919.

Weagant Oscillation Valve

The Weagant Oscillation Valve. Wireless Age, vol. 6, no. 6, Mar. 1919, pp. 24-25, 6 figs. Reported improvement on original Fleming oscillation valve. A plate and a filament are enclosed in a vacuum chamber as usual; a metallic electrostatic control element is placed parallel to electron stream so that its field acts at right angles to latter; this position of control is said to be essential characteristic of tube.

TRANSFORMERS, CONVERTERS, FREQUENCY CHANGERS

Phase Transformers

The Engineering Evolution of Electrical Apparatus—XXXVI. Chas. F. Scott. Elec. Jl., vol. 16, no. 1, Jan. 1919, pp. 28-30, 6 figs. Development of two-phase, three-phase transformation.

The Essentials of Transformer Practice—XVIII. E. G. Reed. Elec. Jl., vol. 16, no. 1, Jan. 1919 pp. 31-32, 9 figs. Transformer connections for phase transformations.

Voltages, Abnormal

Abnormal Voltages Within Transformers, L. F. Blume and A. Boyajian. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 2, Feb. 1919, pp. 211-248, 21 figs. Mathematical analysis of rectangular wave impinging upon a transformer winding and quantitative values of resulting internal voltage stresses in terms of transformer constants; partial applicability of conclusions to abrupt impulses; difference between operating transformer with isolated and grounded neutral; comparison of theoretical results with impulse and high-frequency tests made in laboratory.

TRANSMISSION, DISTRIBUTION, CONTROL

High-Tension Transmission

For High Tension Transmission Service. Power Plant Eng., vol. 23, no. 4, Feb. 15, 1919, pp. 179-183, 5 figs. Description of new Dixon station of Illinois Northern Utilities Co.; modern coal-handling equipment; novel arrangement of intake prevents dirty screens.

Line Tests

Line Tests in Medium-Sized and Small Offices (Essais de lignes dans les bureaux de moyenne et de petite importance), M. Poirier. Annales des Postes, Télégraphes et Téléphones, vol. 7, no. 4, Dec. 1918, pp. 625-627, 2 figs. How to make simple tests with voltmeter.

Phase-Displacement and Power Rates

Phase-Displacement and Its Relation to Methods of Charging for Power. H. Bussmann. Elecn., vol. 82, no. 2122, Jan. 17, 1919, pp. 101-102, 3 figs. Abstract of article in Elektrotechnische Zeitschrift, no. 10, 1918.

Pole Guying

Examples of Pole Guying from Other Fields. Charles Rufus Harte. Elec. Ry. Jl., vol. 53, no. 7, Feb. 15, 1919, pp. 321-324, 5 figs. Deals especially with protection against strains due to storms; refers to subject of pole preservation.

Rectifiers

Connection in Parallel and Voltage Regulation of Mercury-Arc Rectifiers (Marche en parallèle et réglage de la tension des redresseurs de courant à vapeur de mercure). Revue Générale de l'Electricité, vol. 5, no. 6, Feb. 8, 1919, pp. 230-233, 10 figs. Concerning operation of several rectifiers connected in parallel in preference to one single high-power apparatus, where demands call for large supply of power. From Electrotechnische Zeitschrift, vol. 39, Aug. 15, 1918, pp. 321-324.

Substations

A Well-Lighted and Well-Ventilated Substation, S. H. Granten. Elec. Ry. Jl., vol. 53, no. 7, Feb. 15, 1919, pp. 326-327, 4 figs. Description of new substation of Kansas City Rys.

Suspension, Aerial

New Charts for Aerial Suspensions, Joseph N. Le Conte. Jl. Electricity, vol. 42, no. 3, Feb. 1, 1919, pp. 120-122, 4 figs. Graphical representation of relationship of constants involved in suspension design. From paper before San Francisco Section, Am. Inst. Elec. Engrs.

Transmission-Line Computations

Transmission-Line Computations, A. E. Kennelly. Elec. World, vol. 73, no. 8, Feb. 22, 1919, pp. 356-357, 4 figs. Use of hyperbolic functions favored in comparison with alternative methods for calculation of voltage, current and power on long uniform transmission lines.

Wire Sizes

Calculation and Design of Direct Current Circuits, Terrell Croft. Nat. Engr., vol. 23, no. 2, Feb. 1919, pp. 72-75, 3 figs. Determining sizes of wire for distribution of electrical energy; voltage variations for incandescent lamps; apportionment of voltage drop; wiring calculations.

WIRING

Interior Wiring

Approved Interior Wiring Methods, John H. Mayer. Telegraph & Telephone Age, vol. 37, no. 4, Feb. 16, 1919, pp. 83-84. Suggestions in regard to wiring offices for electric light so work will pass inspection.

Civil Engineering

BRIDGES

Franklin-Orleans Bridge

The Franklin-Orleans Bridge. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 16-18, 7 figs. Plans and details of double-leaf trunnion bascule structure over Chicago river.

Howe Truss Spans

Strengthening Howe Truss Spans. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 45-46, 3 figs. Designs prepared by Northern Pacific.

Inspection

Periodic Inspection of Bridges. Eng. & Contracting, vol. 51, no. 9, Feb. 26, 1919, pp. 212-216. From a paper by Herbert C. Keith before the Brooklyn Engineers' Club.

Masonry Bridges

Reconstruction of Masonry Bridges Destroyed During the War (La reconstruction des ponts en maçonnerie détruits au cours des hostilités), M. Lutton. Génie Civil, vol. 74, no. 2, Jan. 11, 1919, pp. 24-26, 4 figs. Suggests building of arched reinforced-concrete segments capable of being conveniently suspended and put in place without necessitating building of heavy falsework.

BUILDING AND CONSTRUCTION

Architects

Post-War Committee on Architectural Practice. Jl. Am. Architects, vol. 7, no. 1, Jan. 1919, pp. 6-8. Announcement of preliminary program for inquiry into status of architect.

The New Architectural Education. Am. Architect, vol. 115, no. 2249, Jan. 29, 1919, pp. 157-160. Report of Sub-Committee on Education of Reconstruction Committee of Illinois Chapter. Am. Inst. Architects and Ill. Soc. Architects.

Booms

Simple Method for Designing Booms, Arthur Raymond. Eng. & Contracting, vol. 51, no. 9, Feb. 26, 1919, pp. 209, 1 fig. Presents method and solves illustrative problem.

Flat-Slab Construction

Design of Exterior Panels in Flat Slab Construction, Albert M. Wolf. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 27-30, 2 figs. Survey of requirements and rulings by various institutions.

Floors

Test of a Flat Slab Floor, Western Newspaper Union Building at Chicago, U. S. A., Arthur N. Talbot and Harrison F. Gonnerman. Contract Rec., vol. 33, no. 7, Feb. 13, 1919, pp. 127-131, 5 figs. Abstract from bul. 106, Univ. of Ill.

Girders

New and Little-Known Methods of Calculation of Girders, Beams and Arches, James S. Martin. Pro. Engrs.' Soc. of Western Pennsylvania, vol. 34, no. 9, Dec. 1918, pp. 579-633 and (discussion) pp. 634-639, 22 figs. Survey of literature; graphic determination of rivet pitch in flanges of riveted girders; principles of graphic integration applied to beams and arches; graphic integration applied to elastic arches.

Long Girders and High Columns Designed as Rigid Frame, A. E. Wynn. Eng. News-Rec., vol. 82, no. 7, Feb. 13, 1919, pp. 340-342, 4 figs. Gymnasium requiring 52-foot span and 20-foot clearance in height carried as third story of building.

The Patterns for Crane Girders, Joseph Horner. Mech. World, vol. 65, nos. 1670 and 1672, Jan. 3 and 17, 1919, pp. 7-8 and 31, 12 figs. Details of girders by which main checks of girders are connected. First and second installments. (To be continued.)

Roofs

Reinforced Concrete Roof for Craneways in Buildings, Albert M. Wolf. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 18-19, 1 fig. Description of reinforced-concrete trusses used to span craneway and shipping court in Ford Motor Co. service building in Chicago.

Roof Construction for Factories with Excessive Moisture, Frederick J. Hoxie. Am. Architect, vol. 115, no. 2249, Jan. 29, 1919, pp. 181-187, 20 figs. Varieties of wood-destroying fungi; examples of rot formation and destruction of beams; reduction of relative humidity by designing for increased temperature, putting more heating pipes near roof or preventing escape of heat through poorly insulated roof planks.

School Buildings

Construction and Equipment of Portable School Buildings, John Howatt and Samuel R. Lewis. Heat. & Ventilating Mag., vol. 16, no. 2, February, 1919, pp. 24-32, 7 figs. Experiences with the use of this type of building with suggestions for its heating and ventilating.

Tanks

Tank Construction, Ernest G. Beck. Mech. World, vol. 65, no. 1671, Jan. 10, 1919, pp. 18-19, 6 figs. Side walls of rectangular tanks. Twenty-fourth installment. (Continuation of serial.)

Trestles

Reinforced Concrete Trestles at North Toronto. Ry. Gaz., vol. 30, no. 1, Jan. 3, 1919, pp. 15-16, 3 figs. Details of structure involving 13,500 cu. yd. of concrete and 670 tons of reinforcing steel.

Viaducts

Design and Construction of Reinforced Concrete Viaducts, at Mileages 0.9 and 1.8 North Toronto Subdivision, of the Canadian Pacific Railway, B. O. Eriksen and H. S. Deubelbeiss. Jl. Eng. Inst. Can., vol. 2, no. 2, Feb. 1919, pp. 93-101, 20 figs. Slabs 36 ft. long were premolded and bulk of concrete cast in forms on the ground.

Walls

Conditions for Economy in Reinforced Concrete Wall Design, George Paaswell. Eng. & Contracting, vol. 51, no. 9, Feb. 26, 1919, pp. 226-227, 1 fig. Develops a method of comparing an "L" or "T" shaped wall with a counterforted wall to determine the height at which the latter becomes the more economical.

Wharves

Construction of the St. Louis Municipal Wharf. Ry. Rev., vol. 64, no. 8, Feb. 22, 1919, pp. 275-279, 8 figs. Description of engineering features of construction, with drawings and photographs of details of work in progress.

CEMENT AND CONCRETE

Cement Production

The Production of Cement, Lime, Clay Products, Stone, and Other Structural Materials in Canada During the Calendar Year 1917. Can. Dept. of Mines, no. 500, 44 pp. Report of Chief of Mineral Resources and Statistics.

Gravity Concreting

Placing Concrete by Gravity in Block-Frames (La mise en place du béton par gravité dans les chantiers de constructions civiles ou de travaux publics). Génie Civil, vol. 74, no. 2, Jan. 11, 1919, pp. 21-24, 13 figs. Details of falsework and auxiliary machinery. Schemes of various American builders.

Pneumatic Concreting

The Pneumatic Method of Concreting. H. B. Kirkland. Jl. Western Soc. Engrs., vol. 23, no. 5, May 1918, pp. 319-349 and (discussion) pp. 349-355, 27 figs. Method consists in blowing batches of concrete through a pipe from a central point of supplies to their place in concrete forms; materials for a batch of concrete (1-2 cu: yd.) are proportioned in a measuring device and dropped into the pneumatic mixer without previous mixture.

Progress in 1918

Concrete and Cement. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 27. New applications given to concrete and reinforced concrete in 1918.

Slag Concrete

Blast Furnace Slag in Concrete and Reinforced Concrete, J. E. Stead. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 36-38. Laboratory tests to determine whether blast-furnace slag has any corrosive action on iron and steel placed in contact with it. (To be continued.) From Lond. Eng.

Solubility of Cement

The Solubility of Portland Cement and Its Relation to Theories of Hydration, J. C. Witt and F. D. Reyes. Philippine Jl. Sci., vol. 13, sec. A, no. 4, July 1918, pp. 147-161, 1 fig. It is reported as result of experiments that when cement is shaken with water in a closed vessel large amounts of calcium with relatively small amounts of most other elements present go into solution, and that the factors that effect results are (1) absence of carbon dioxide, (2) method of agitation, (3) fineness of grain, (4) volume of water, and (5) time.

Wasteful Construction

Useless Waste in Concrete Construction Due to Legal Requirements. W. Stuart Tait. Am. Architect, vol. 115, no. 2249, Jan. 29, 1919, pp. 187-189, 1 fig. Criticism of basing design methods on strength for 1-2-4 concrete at 28 days of 2,000 lb. per sq. in. (Continuation of serial.)

See also MINING ENGINEERING, Mines and Mining (Cement Gun).

HARBORS

Seattle

Seattle Starts Large Expansion of Her Public Port Facilities, Frank Carleton Teck. Marine News, vol. 5, no. 9, Feb. 1919, pp. 98-99, 1 fig. Type and equipment of proposed additional pier 2,700 ft. long.

The Port of Seattle, W. A. Scott. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 61-63, 4 figs. Freight-handling equipment.

Shore Protection

Coastal and Shore Protection, H. Colin Campbell. Eng World, vol. 14, no. 4, Feb. 15, 1919 pp. 11-17, 7 figs. Breakwaters, sea walls, and revetment work in various locations and under various conditions.

IRRIGATION AND RECLAMATION

Arid Lands

Post War Reclamation of Arid Lands, S. O. Andros. Eng World, vol. 14, no. 2, Jan. 15, 1919, pp. 19-22, 8 figs. Butte project, other Government projects and private projects.

Irrigation Project

Preliminary Project for Irrigating the Chancay Pampas (Proyecto preliminar de irrigación de las pampas de Chancay), Carlos W. Sutton and Juan N. Portocarrero y C. Boletin del Cuerpo de Ingenieros de Minas del Peru, no. 94, 1918, 24 pp. 2 figs. Involves irrigation of 15,000 hectares.

Irrigation Prospects

Some Financial, Agricultural and Engineering Aspects of Irrigation, Charles Kirby Fox. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 30-31. Statistics in United States; question of transportation; outlook of future developments.

Preliminary Work

Preparing Six Hundred Acres of Land for Irrigation, F. W. Herron. Eng. News-Rec., vol. 82, no. 7, Feb. 13, 1919, pp. 337-339, 2 figs. Soil studies, surveys, supply and drainage ditches; land leveling and ditch construction operations.

Swamp Lands

Reclamation of Swamp Lands in Dane County, Wisconsin, W. G. Kirchoffer. Mun. & County Eng., vol. 56, no. 2 Feb. 1919, pp. 65-66. Work in straightening and deepening main drainage line of marsh and in providing a main outlet; 129,349 acres drained since 1908.

MUNICIPAL ENGINEERING

Town Planning

Town Planning, Thomas Adams. Can. Engr., vol. 36, no. 7, Feb. 13, 1919, pp. 215-216. Concerning town development in Quebec. From South Shore Board of Trade Rev.

ROADS AND PAVEMENTS

Brick Paving

Latest Seattle Specifications for Brick Paving Are for the Monolithic Type, W. H. Tiedeman. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 13-14. Writer prefers cement-grout filler and believes sand-cement "cushion" fails.

The Brick Highways of Ashtabula County, Ohio, Ray N. Case. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 53-57, 17 figs. County engineer believes slag bed desirable to give stability and gives account of developments and results.

Canada

Federal Aid for Highways, J. D. Reid. Can. Engr., vol. 36, no. 7, Feb. 13, 1919, pp. 223-224. Plans of the Dominion Government.

Good Roads in Lanark County, C. J. Foy. Contract Rec., vol. 33, no. 7, Feb. 12, 1919, pp. 141-144, 2 figs. Account of developments. Before convention of Eastern Ontario Good Roads Assn.

Construction

Arching an Underground Roadway With Concrete Blocks, W. Ross. Iron & Coal Trades Rev., vol. 98, no. 2657, Jan. 31, 1919, p. 141, 4 figs. Method to conduct excavating and building simultaneously, the packing being done as material is produced at face.

Road Contractor Successfully Employs Portable Charging Bins to Eliminate Dumping and Wheeling on Subgrade in Concrete Road Construction, George A. Burley. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 11-12, 2 figs. Comparison of bin method and dumping on subgrade.

Utilizing More Mechanical Devices on Road Construction, Frank F. Rogers. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 18-20. Reports of various county engineers of Michigan.

Earth Roads

Can Earth Roads Be Made Satisfactory? H. S. Carpenter. Jl. Eng. Inst Can., vol. 2, no 2, Feb. 1919, pp. 102-104. Suggestions in regard to selection of material, placing it on roadbed and estimates of cost of earth, sand-clay, gravel and macadam roads.

Financing

How the Successful Campaign for the $60,000,000 Good Roads Bond Issue was Conducted in Illinois, S. E. Bradt. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 3-5, 1 fig. Organization chart of workers.

Florida

Lessons Taught by Road Building Experience in Florida, G. Robert Ramsey. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 73-74. Influence of distance from manufacturing centers, productive area, assessed valuations, etc.

Foundations

Engineers Must Study Road Foundations. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 31-35. Suggests that foundations be constructed with a view to bearing the greatest possible load under all conditions.

Good-Roads Movement

National Highways and Good Roads, J. A. Duchastel de Montrogue. Jl. Eng. Inst. Can., vol. 2, no. 2, Feb. 1919, pp. 91-92. Comparison of situations in U. S. and Canada with reference to act, passed by U. S. Congress, destined to aid several states in road construction.

The Federal Aid Road Law; Experience to Date and Suggestions for Better Co-operation, Logan Waller Page. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 20-23, 10 figs. Various federal aid road projects; amendments to law. Written for presentation before Am. Assn. State Highway Officials.

Twenty-Five State Highway Engineers Report Their Plans for 1919. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 46-51. Letters state funds available and plans in detail.

Highway Pavements

City Pavements for State Highway in Connecticut, Charles J. Bennett. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 62-63. Sheet asphalt on concrete base.

New York

Highway Work in Four New York Boroughs, Good Roads, vol. 17, no. 8, Feb. 22, 1919, pp. 69-71 and 84, 4 figs. Résumé of outstanding features of road and street work in Brooklyn, Bronx, Queens and Richmond.

Roads of New York, E. A. Bonney. Good Roads, vol. 17, no. 8, Feb. 22, 1919, pp. 73-76 and 84, 8 figs. Historical sketch of development of N. Y. State Highway Department, with review of its organization and accomplishments.

Street Work in Manhattan. Good Roads, vol. 17, no. 8, Feb. 22, 1919, pp. 67-68 and 78, 3 figs. Historical sketch of development of highway operations.

Sand-Clay Roads

Experience with Sand Clay Road Surfacing in Nebraska, George E. Johnson. Mun. & County Eng., vol. 56, no. 1. Jan. 1919, pp. 9-11, 3 figs. Location of materials and their properties.

Snow Removal

Snow Removal from New York State Highways, Edwin Duffey. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 23-24. Concerning snow-removal legislation.

Wood-Block Paving, Base for

Method Employed in Minneapolis in Constructing Smooth Surfaced Concrete Base for Wood Block Paving, Ellis R. Dutton. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 51-52, 2 figs. Concrete surface smoothed over with small roller on templets.

SANITARY ENGINEERING

Drain Pipe

Aligning Drain Pipe, Harry Gardner. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 45-46, 1 fig. Method of giving grade and line for pipe sewer construction.

Latrines

A Mine Latrine, William W. Cort. Min. & Sci. Press, vol. 118, no. 5, Feb. 1, 1919, pp. 155-157, 3 figs. Details of latrine and sanitary arrangements connected with it. From bul. 28 of Cal. State Board of Health, Sanitation in Mines for the Prevention and Eradication of Hookworm.

Sanitation

Sanitation in Emergency Shipyards, W. L. Stevenson. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 70-71, 2 figs. Methods of distributing drinking water; collection and disposal of wastes; fly and mosquito extermination.

Sewage Disposal

Sewage Disposal in Kansas, F. M. Veatch, H. P. Evans and L. E. Jackson. Bul. Univ. Kan., vol. 18, no. 18, Dec. 1, 1917, 40 figs. Discussion of practice in certain municipalities, together with instructions to plant operators.

Sewage Disposal at Manchester. Can. Engr., vol. 36, no. 7, Feb. 13, 1919, pp. 222-223. Results of operation and activitated sludge investigations at Withington and Davyhulme works. From Surveyor, London.

Sewage Disposal Works in Reconstruction Period, Harrison P. Eddy. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 60-62. Data relating to cost of certain sewage disposal projects built under ante-war conditions, and proportion of budget likely to be required to meet annual charges.

Sewers

Some Design and Constructional Features of the Rideau River Intercepting Sewer, Ottawa, Canada, L. McLaren Hunter. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 63-65, 4 figs. Sewer is 17,900 ft. long, with 400-ft. tunnel section under railway tracks.

The Selection of the Value of the Factor "n" in Sewer Design, Paul E. Green. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 52-53. Attempt to demonstrate that *n* (in Kutter formula) has wrongly been recommended by experimenters as varying between 0.013 and 0.015 for vitrified-tile pipe sewers. Writer believes construction conditions determine value of *n*.

-endurance
Endurance means long life —hence economy
If you want a hack saw to endure—use one made for your particular cutting requirement.
Starrett Hack Saws
are made to endure—to last long and are truly economical because there is a saw for any job.
Our Hack Saw Chart
will tell you quickly which is the proper saw to use for every metal. Keep it before you. Write today also asking for Catalog No. 21 LD on Starrett fine precision tools.
The L. S. Starrett Company
The World's Greatest Tool Makers. Manufacturers of Hack Saws Unexcelled.
Athol, Mass.
42-897
STARRETT TOOLS

Swimming Pools

Keeping Swimming Pools Pure and Wholesome—IV. Metal Worker, vol. 91, no. 3, Jan. 17, 1919, pp. 86-87, 1 fig. Installation of ozoning apparatus. (Concluded.)

SURVEYING

Chains

Metallic Chains Used in Geodic Surveys (Fili e nastri metallici nella misura delle basi geodetiche), G. Cicconetti. Il Nuovo Cimento, vol. 15, nos. 5-6, May-June 1918, pp. 180-190. Remarks on Jadering's method for obtaining accurate base measurements.

See also AERONAUTICS, Applications (Surveying and Mapping).

WATER SUPPLY

Conservancy

Water Works Conservancy, Arthur A. Reimer. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 24-29. Economical utilization and salvaging undertakings.

Electrical Control

Automatic Electrical Control at the Deer Trail, L. Brandenburger. Salt Lake Min. Rev., vol. 20, no. 21, Feb. 15, 1919, pp. 25-26, 3 figs. Diagrammatical sketch. Plant supplies 30,000 gal. water per day to flotation and cyanide mill.

Filter Plant

Need of Certain Investigations for Increasing the Efficiency of Water Filter Plant Design and Operation, James W. Armstrong. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 5-6. Most efficient mix with least loss of head; time and intensity of agitating; coagulation-basin design.

Hardness

Advantages and Disadvantages of Hard City Water. (Vorteile und Nachteile der Wasserhaerte) Dr. Carl Opitz. Journal fuer Gasbeleuchtung und Wasser-Versorgung, vol. 61, no. 41, Oct. 12, 1918, pp. 482-485. Reviews the relative effects of the water supplied upon the physical condition of 87,617 school children in 158 towns in Germany and finds that the harder the water, the better preserved are the teeth, nervousness and other ills are also diminished.

Purification

Features of Present-Day Water Purification Practice, Milton F. Stein. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 57-60, 4 figs. Non-technical review written for municipal officials.

Notes on Chlorine Treatment of London, England, Water Supply, A. C. Houston. Mun. & Coun. Eng., vol. 56, no. 1, Jan. 1919, pp. 29-30. From report of Director of Water Examination.

Chlorination of Chicago's Water Supply, John Ericson. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 68, 2 figs. Diagram indicating operation of Miller aeriostat.

Reservoirs

The Water Supply for Montevideo. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 23-26, 16 figs. Design and construction of concrete reservoir at Uruguay capital.

An Interesting Nile Scheme. Elec. Times, vol. 55, no. 1422, Jan. 16, 1919, pp. 35-37, 1 fig. Reservoir project in Sudd region. Paper before Sultanieh Geographical Soc., Cairo.

Waterworks Operation: Reservoir Maintenance. Mun. Jl., vol. 46, no. 4, Jan. 25, 1919, pp. 65-67. Methods, costs, figures and results.

Water-Works Operation

Effect of War Conditions on the Operation and Maintenance of Water Works. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 16-17. Cost of principal materials and supplies, 1914-1918; unskilled labor prices per hour.

WATERWAYS

Hudson River

Government Work on Hudson River. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 11-15, 7 figs. Removal of old works and construction work involved in erection of dam in N. Y. State barge canal at Troy.

Niagara

Mapping Niagara at the Brink. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 39-40, 2 figs. Apparatus used in sounding river just above fall.

Saone River

The Navigable System of the Saone River (Le réseau navigable de la Saone). Génie Civil, vol. 73, no. 24 Dec. 14, 1918, pp. 466-468, 1 fig. System consists of five routes disposed in fan shape. Data are given on organization, arrangement and operation.

Mining Engineering

BASE MATERIALS

Bauxite

Bauxite (La bauxite), Ed. Decamps. Métaux, Alliages et Machines, vol. 12, no. 1, Jan. 1919, pp. 3-8. Patented processes of precipitating aluminum from bauxite, manufacturing artificial emery (crystallized aluminum) and making refractory products.

Black Sand

Notes on the Black Sand Deposits of Southern and Northern California, R. R. Hornor. Department of Interior, Bur. of Mines, tech. paper 196, 42 pp. 14 figs. Investigation conducted by Bur. of Mines in order to determine whether any of deposits are large enough to be profitably exploited, and also possibility of commercial utilization of base minerals.

Clays

Microscopic Examination of Clays, R. E. Somers. Jl. Wash. Acad. Sci., vol. 9, no. 5, Mar. 4, 1919, pp. 113-126. Report of microscopic examinations undertaken in order to determine minerals contained in clays, and study of thin sections of burned samples.

Magnesite

Magnesite and Dolomite in Australia and New Zealand, P. G. Morgan. New Zealand Jl. Sci. & Technology, vol. 1, no. 6, Nov. 1918, pp. 359-372. Reports of mines departments of Australian states concerning supply of magnesite or dolomite; New Zealand occurrences.

Magnesite, Its Occurrence and Uses, T. Crok. Min. Mag., vol. 20, no. 2, Feb. 1919, pp. 115-120. Historical account of magnesite applications and utilization in smelting industry. (To be continued.) Paper before Swansea meeting of Ceramic Soc.

Rock Quarries

Maori Rock-Quarries on D'Urville Island, J. Allan Thomson. New Zealand Jl. Sci. & Technology, vol. 1, no. 6, Nov. 1918, pp. 321-322, 1 fig. Quarries consist mainly of serpentine, associated in some parts with amphibolites derived from doleritic or gabbroid rocks.

COAL AND COKE

Breakers and Cleaners

Bradford Coal Breakers and Preliminary Mechanical Cleaner. Coal Age, vol. 15, no. 8, Feb. 20, 1919, pp. 352-355, 2 figs. Construction and operation; account of results obtained at various commercial plants.

Canada

Coal Production in Canada—Its National Significance, F. W. Gray. Can. Min. Jl., vol. 40, no. 5, Feb. 5, 1919, pp. 73-74. Urges that mining industry be represented in federal parliament.

The Production of Coal and Coke in Canada During the Calendar Year 1917, John McLeish. Can. Dept. of Mines, no. 501, 39 pp. Report of chief of Division of Mineral Resources and Statistics.

Coke Ovens

Some Economic Considerations in Coke-Oven Practice, W. Colquhoun. Trans. Instn. Min. Engrs., vol. 56, part 2, Dec. 1918, pp. 61-79 and (discussion) pp. 79-90, 6 figs. Claims that process of coking cannot be called economically perfect until some inventor devices a more direct application of the heat necessary to distill the coal.

Costs, Mining

Anthracite Mining Costs, R. V. Norris. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 249-262, 5 figs. Adjustments of cost from a reported to a price-fixing basis; charts showing cost of production; accounting suggestions. Based on cost reports for 6-months' period, Dec. 1917 to May 1918, as compiled by Federal Trade Commission.

Great Britain, 1918

Coal-mining. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 21. Conditions in United Kingdom in 1918 and comparison with conditions in previous years.

Impurities

Impurities in Raw Coal and Their Removal, T. J. Drakely. Colliery Guardian, vol. 117, no. 3031, Jan. 31, 1919, p. 245. Three methods of separating impurities from coal: hand picking; mechanical shale pickers; coal washers. Also in Iron & Coal Trades Rev., vol. 98, no. 2657, Jan. 31, 1919, p. 131.

Water Supply

Water Supply at Coal Mines, Carl Scholz. Coal Age, vol. 15, no. 9, Feb. 27, 1919, p. 391, 1 fig. Location of well and pipe line at Valier Coal Co.'s mine.

Western Europe

Coal Resources of the Western Front, II. H. Stock. Black Diamond, vol. 61, no. 26, vol. 62, no. 1, Dec. 28, 1918, Jan. 4, 1919, pp. 576-578 and 5-7, 10 figs. Maps and statistics of coal and iron fields in Northern France (including Alsace-Lorraine) Belgium and Western Germany.

Lens—The Coal Field of France, Frank Haas. Coal Age, vol. 15, no. 9, Feb. 27, 1919, pp. 392-394, 11 figs. How French coal mining at Lens was conducted before German invasion.

COPPER

Copper Industry

The Position of Copper Analyzed. Min. & Sci. Press, vol. 18, no. 8, Feb. 22, 1919, pp. 243-244. Official statement of Federal Government.

World Production and Consumption of Copper (La production et la consommation mondiales du cuivre). Métaux, Alliages et Machines, vol. 12, no. 1, Jan. 1919, pp. 12-13.

Michigan

The Porphyry Intrusions of the Michigan Copper District, Thomas S. Woods. Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, pp. 299-302, 3 figs. Relation of fine-grained volcanics to mineralization of Michigan copper-bearing formations.

EXPLOSIVES

Explosives

Explosives, Robert S. Lewis. Min. & Sci. Press, vol. 118, no. 8, Feb. 22, 1919, pp. 245-253, 14 figs. Compilation of data, tables and manufacturing methods. From various Bur. of Mines bulletins.

GEOLOGY AND MINERALOGY

Chile

The Veins of Chanarcillo, Chile, W. L. Whitehead. Economic Geol., vol. 14, no. 1, Jan.-Feb. 1919, pp. 1-45, 6 figs. Based upon tests of ores in laboratories of Mass. Inst. Technology and supplemented with geological studies of district. Ores contain silver and copper.

Copper Silicates

Plancheite and Shattuckite, Copper Silicates, are not the same Mineral, Waldemar T. Schaller. Jl. Wash. Acad. Sci., vol. 9, no. 5, Mar. 4, 1919, pp. 131-134. Results of investigation of United States Geological Survey.

Earth Structure

On the Internal Structure of the Earth, J. T. Morrison. South African Jl. Sci., vol. 15, no. 2, Sept. 1918, pp. 31-44, 3 figs. Discussed from viewpoint of geophysics. Curves of earth-wave paths, longitudinal vibrations, and transverse vibrations.

Haiti

A Geological Reconnaissance in Haiti. A Contribution to Antillean Geology, William F. Jones. Jl. Geol., vol. 26, no. 8, Nov.-Dec. 1918, pp. 728-752, 10 figs.

Volcanoes

Sancy Volcano: Its Secondary Volcanoes and Lavas (Le Volcan du Sancy. Ses volcans secondaires et ses laves), Ph. Glangeaud. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 27, Dec. 30, 1918, pp. 1076-1078, 1 fig. Geological characteristics.

Volcano Model (Un modèle de volcan), Robert W. Sayles. Revue Générale des Sciences, vol. 29, no. 23, Dec. 15, 1918, pp. 661-666, 6 figs. Construction of 12-ft. model of Kilauea volcano in Hawaii.

IRON

Arizona

Magnetic Iron Ore in Arizona, Sydney H. Ball and T. M. Broderick. Eng. & Min. Jl., vol. 107, no. 8, Feb. 22, 1919, pp. 353-354, 2 figs. Geological characteristics of gabbro differentiates in Eureka district.

Goodman Shortwall Machines

Virginia Iron, Coal and Coke Company and Its Goodman Shortwall Machines. Elec. Min., vol. 16, no. 1, Jan. 1919, pp. 3-22, 50 figs. Details of mining operation and electric power house.

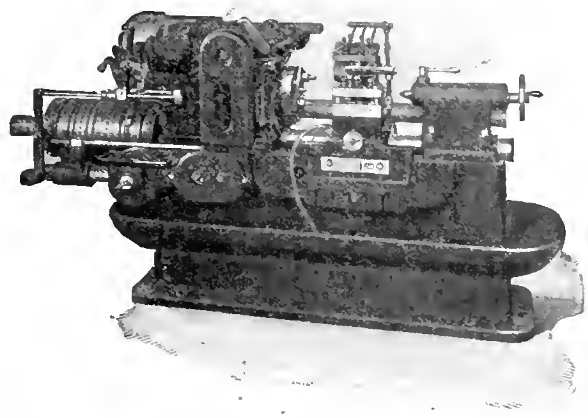
Magnetic Concentration

The Magnetic Concentration of Iron Minerals at Mineville, United States (La concentration magnétique des minerais de fer à Mineville [E.-U.]). Génie Civil, vol. 73, no. 25, Dec. 21, 1919, pp. 495-496, 3 figs. Equipment of Barton Hill mine.

Statistics

Iron Ore Production for 1918 Decreased. Iron Trade Rev., vol. 64, no. 8, Feb. 20, 1919, p. 514. 72,192,000 tons in 1918; 75,573,207 tons in 1917.

The Fay Automatic Lathe



The Fay Automatic Lathe is a real lathe, with nine-speed, all-steel geared headstock with three automatic speed changes, tailstock, carriage and bed. It differs from the engine lathe in the details of its mechanism, which fit it especially for the particular work it is designed to do. There is also the added mechanism required to make it automatic in all its motions.

FIELD: The Fay Lathe is designed for the automatic turning of work held on centers. It is thus adapted to work which is itself centered, or to work which is mounted on an arbor.

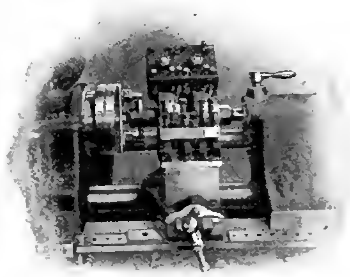
In the class of *centered work* are included such standard parts as steering knuckles for automobiles, pinion shafts for transmissions, forgings in general of such shape as to be turned rather than chucked, and many miscellaneous castings of the same type.

In the class of *work done on arbors* is included the large variety of parts which in ordinary practice is turned in the engine lathe by this means, as pulleys either straight-faced or crowned, gear blanks, flanges, disks, hubs, and a thousand and one other pieces of the kind used in textile machinery, automobiles, machine tools, electrical work and machine building in general.

Second operation work is the legitimate field of the Fay Lathe.

Furthermore, it has a large field of usefulness in the accurate finishing of parts roughed out on other and less accurate automatic machines.

On the work described above the Fay Lathe will do straight turning, taper turning, form turning, straight facing, bevel facing, recessing, singly or in combination, with roughing or finishing cuts. It will do everything of this sort except threading, for which it is not adapted.



Profitable Work for the Automatic Lathe

Advantages of the Fay Automatic

1. Ease of setting.
2. Rapidity of changing work.
3. Two pieces at a time.
4. Multiple tooling.
5. Taper turning and bevel facing.
6. Form turning.
7. Turned surfaces free from scoring on the return movement.
8. Flexibility of mechanism.
9. Facing and turning simultaneously.
10. One operator runs two machines.

LEAD

Burma

Operations of the Burma Mines, Ltd., A. B. Parsons. Eng. & Min. Jl., vol. 107, no. 6, Feb. 8, 1919, pp. 257-262, 2 figs. Lead-silver-zinc mining in Namtu, Northern Shan States, Upper Burma.

Missouri-Kansas-Oklahoma

Mining and Milling of Lead and Zinc Ores in the Missouri-Kansas-Oklahoma Zinc District, Clarence A. Wright. Department of Interior, Bur. of Mines, bul. 154, 134 pp., 30 figs. Methods used and indication of conditions that affect their efficiency.

MAJOR INDUSTRIAL MATERIALS

Manganese

Manganese Ore Deposits in Cuba, Ernest F. Burchard. Bul. Am. Inst. Min. Engrs., no. 147, Mar. 1919, pp. 591-595. Location, character, quantity, and availability of manganese- and chrome-ore deposits.

Manganese Ore in Uruguay. Min. & Sci. Press, vol. 118, no. 8, Feb. 22, 1919, p. 253. U. S. Consular report from Montevideo.

Problems Involved in Concentration and Utilization of Domestic Low-Grade Manganese Ore, Edmund Newton. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 379-389. Manganese deposits in U. S.; metallurgical requirements of steel industry; concentration of domestic low-grade manganese ores; characteristics of ore affecting beneficiation.

Manganese and Chromium

Manganese and Chromium in California, Walter W. Bradley, Emile Huguenin, C. A. Logan, W. Burling Tucker and Clarence A. Waring. Cal. State Min. Bur. bul. 76, Aug. 1918, 248 pp., 56 figs. Characteristics of deposits, classification and description of mines, and report on economical conditions of mining these two minerals.

MINES AND MINING

Africa

The Mineral Industry of the Union of South Africa and Its Future, P. A. Wagner. South African Jl. Sci., vol. 15, no. 2, Sept. 1918, pp. 45-78. Survey of resources; statistics of production; expected future developments.

The Mineral Resources of Rhodesia, F. P. Mennell. S. A. Jl. Industries, vol. 1, no. 15, Nov. 1918, pp. 1411-1417. Asbestos; coal; arsenic; barites; diamonds and other precious stones; corundum; graphite; magnesite; mica; salt; soda; talc. (Second article.)

Canada

Mining Development in Northern Manitoba, R. C. Wallace. Bul. Can. Min. Inst., no. 83, Mar. 1919, pp. 287-296. Proposes building of railway along mineral belt.

Caps, Steel

The Crushing of Steel Caps, A. C. Stoddard. Min. & Sci. Press, vol. 118, no. 8, Feb. 22, 1919, pp. 258-259, 3 figs. Operations in rearrangement of haulage drifts at Inspiration Consolidated Copper Co.

Cement Gun

Use of the Cement Gun in a Bituminous Coal Mine, M. S. Sloman. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 56-57, 1 fig. Figures showing costs on length of 900 ft. of slope; results obtained.

Coöperation

Coöperation Among Small Mines with a View to Increasing Efficiency of Operation, R. W. Brigstocke. Bul. Can. Min. Inst., no. 83, Mar. 1919, pp. 283-286. Its value in permitting employment of staff of specialists.

Development

Examining and Developing the Mine Prospect, Harry T. Curran. Eng. & Min. Jl., vol. 107, no. 8, Feb. 22, 1919, pp. 343-348. Writer's views concerning what should constitute sufficient information to justify development of a prospect.

Dredging Areas

Topography and Geology of Dredging Areas III, Charles Janin. Min. & Sci. Press, vol. 118, no. 4, Jan. 25, 1919, pp. 122-123, 4 figs. Dredgings areas in Colo., Mont., Idaho and Oregon. Abstract from bul. 127, U. S. Bur. of Mines.

Financial Problems

The Banker and Mining Frank B. Anderson. Min. & Sci. Press, vol. 118, no. 8, Feb. 22, 1919, pp. 254-256. National economy as a solution of financial problems created by war. Claims mere increase of metal will not suffice. Address delivered before Cal. chapter, Am. Min. Congress.

Health Control

Prevention of Illness Among Employees in Mines, A. J. Lanza. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 435-437. Points out advisability of securing for underground work employees who are free from organic and anatomical defects and of maintaining working conditions underground on a high plane of sanitation and efficiency.

Humidity

Humidity of Deep Mines, Sydney F. Walker. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 43-44. Suggests that each mine be treated in same manner as cold-storage plants.

Laws

Abstracts of Current Decisions on Mines and Mining, J. W. Thompson. Dept. of Int., Bur. of Mines, bul. 172, law serial 16, 160 pp. Minerals and mineral lands; eminent domain; mining terms; mining corporations and partnerships; mining claims; statutes relating to mining operations; leases and properties; quarry operations; damages for injuries to miners; publications relating to mining lands.

Discharging Water from Mining Plants, Chesla C. Sherlock. Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, pp. 311-312. Legal aspect of pollution of streams by mining operations. Reference is made to similar discussion in Eng. & Min. Jl. Nov. 16, 1918, p. 861.

Mining Law and Economics—V, David Bowen. Colliery Guardian, vol. 117, no. 3029, Jan. 17, 1919, p. 133. Ownership of minerals in British colonies and other countries.

Longwall

Regarding Longwall, F. A. Pocock. Coal Age, vol. 15, no. 9, Feb. 27, 1919, pp. 395-396, 1 fig. Proposes five-entry system of mining, employing longwall faces both advancing and retreating.

Prospecting

Concreting Prospect Drill Holes, Roy H. Poston. Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, pp. 309-311, 4 figs. Plugging with concrete exploratory drill penetrations through strata in order to prevent formation of Channels for underground water.

Safety Devices

Safety Lamp Gauzes, T. J. Thomas, pts. II and III. Colliery Guardian, vol. 117, nos. 3029 and 3031, Jan. 17 and 31, 1919, pp. 134-135 and p. 246, 1 fig. Jan. 17: Survey of tests with Davy lamps Jan. 31: Statements from report of Royal Commission on Accidents in Mines.

The Eudiogrisoumeter Gas Tester, E. Hauser. Colliery Guardian, vol. 117, no. 3031, Jan. 31, 1919, p. 247, 3 figs. Researches to simplify volumetric determination, by combustion, of quantity of inflammable gas contained in a gaseous mixture.

Savoy

The Ore Minerals of Savoy, J. Morrow Campbell. Min. Mag., vol. 20, no. 2, Feb. 1919, pp. 76-88 and (discussion) pp. 88-89, 2 figs. Occurrence; source and method of segregation; origin of veins and how they are filled; order in which minerals developed in wing; decomposition of wolfram.

Shaft Pillars

Removal of a Vertical Shaft Pillar. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 50-52, 1 fig. Account of collapse of shaft pillar and work done to remove it, at Village Main Reef Gold Mine, Witwatersrand.

Shoveling

A Study of Shoveling as Applied to Mining, G. Townsend Harley. Coal Age, vol. 15, nos. 7 and 8, Feb. 13 and 20, 1919, pp. 314-322 and 356-364, 36 figs. Series of tests to determine under what condition a laborer would handle greatest tonnage of muck in a given time, both underground and on the surface.

Statistics

A General Summary of the Mineral Production of Canada During the Calendar Year 1917, John McLeish. Can. Dept. of Mines, no. 499, 27 pp. Report of Chief of Division of Mineral Resources and Statistics.

Metal Production for 1918 in Some of the Western States. Min. & Oil Bul., vol. 5, no. 2, Jan. 1919, pp. 87-88. Ariz., Utah, New Mexico and Oregon. From estimates prepared by U. S. Geol. Survey.

Taxation

Principles of Mining Taxation, Thos. W. Gibson. Bul. Can. Min. Inst., no. 83, Mar. 1919, pp. 273-282. Discussion of methods of evaluating mines and of plans of establishing tax rates. Before joint session Am. Inst. Min. Engrs. and Can. Min. Inst.

Timber Handling

Economical Timber Handling Plant at an Anthracite Mine, Ralph A. Smith. Coal Age, vol. 15, no. 8, Feb. 20, 1919, pp. 350-351, 8 figs. Timber shipped in to plant from a distance is unloaded by haulage transfer system, and cut into lengths suitable to use as props.

Timbering

Inclined Shaft Timbering and a Method of Alignment, Arthur Neustaedter. Eng. & Min. Jl., vol. 107, no. 8, Feb. 22, 1919, pp. 349-351, 1 fig. Method of inclined-shaft instrumental alignment.

Timbering in English Mines. Coal Age, vol. 15, no. 9, Feb. 27, 1919, pp. 400-403, 8 figs. Methods of timbering in longwall workings. Steel and concrete are used as substitutes in roof support.

Transportation

Linking Up Isolated Mineral Districts by the Loco.-Tractor Transport System, Frank Dutton. Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, pp. 313-314, 1 fig. System uses trucks running wholly on light rails. From South African Jl. of Industries.

Tunnels

The Tintic Drain Tunnel and Its Objects, E. E. Grimes. Salt Lake Min. Rev., vol. 20, no. 21, Feb. 15, 1919, pp. 21-23, 4 figs. Tunnel provides drainage for deeper levels of Tintic mining district and double-track haulage facilities.

Tunnel Driving at Copper Mountain, B. C., Oscar Lachmund. Bul. Am. Inst. Min. Engrs., no. 147, Mar. 1919, pp. 579-583, 1 fig. Details of straight adit 2,900 ft. long.

Ventilation

Effect of the Velocity of Ventilating Current Upon Mine Explosions, G. S. Rice and W. L. Egy. Coal Age, vol. 15, no. 7, Feb. 13, 1919, pp. 308-309, 1 fig. Experiments carried on at experimental mine of Bur. of Mines are reported to disprove theory that ventilation should be reduced during firing.

MINOR INDUSTRIAL MATERIALS

Barium

Future of the Barium Industry, William H. Rollin. Chem. & Metallurgical Eng., vol. 20, no. 4, Feb. 15, 1919, pp. 163-164. How industry would be affected by action of Government in raising a protective tariff. Before Am. Inst. Chem. Engrs.

The Barite Deposits of Missouri, W. A. Tarr. Economic Geol., vol. 14, no. 1, Jan.-Feb. 1919, pp. 46-67, 4 figs. Writer advances theory that barite has been deposited by rising thermal solutions which derived their barium and other mineral content from deep-seated igneous rocks.

Electric Power

Oil Production Increased by the Electric Motor. Min. & Oil Bul., vol. 5, no. 2, Jan. 1919, pp. 77-79 and 91, 2 figs. Installation of variable speed 15-30 hp. oil well motor with controller and equipment, used for pumping, swabbing, pulling and cleaning oil wells.

Geology

Magnetic Disturbances and Oil Pools, Hamilton E. Anderson. Oil & Gas Jl., vol. 17, no. 37, Feb. 14, 1919, pp. 52 and 56, 1 fig. Survey of researches undertaken and available data concerning petroleum geology. Work done with a magnetic declinometer of writer's invention.

Graphite

The Graphite Industry, Charles Spearman. Can. Min. Jl., vol. 40, no. 6, Feb. 12, 1919, pp. 87-88. Flotation process of concentration.

Molybdenum

Standard Minerals Molybdenum Mine and Mill. Min. & Oil Bul., vol. 5, no. 2, Jan. 1919, pp. 73-74 and 102, 4 figs. Operations and flow sheet of Standard Minerals Co., Ariz.

Nickel

Nickel in South Africa, T. G. Trevor. Min. Mag., vol. 20, no. 2, Feb. 1919, pp. 120-122. Deposits and their possibilities.

Nickel, T. G. Trevor. S. A. Jl. Industries, vol. 1, no. 15, Nov. 1918, pp. 1385-1394. Occurrences of nickel in Union of South Africa; description of deposits.

Nitrates

The Chilean Nitrate Industry During 1918, Donald F. Irvin. Eng. & Min. Jl., vol. 107, no. 6, Feb. 8, 1919, pp. 265-267. Processes of mining; forecasts of future development.

Tungsten

Experiments Relating to the Enrichment of Tungsten Ores, R. W. Gannett. Economic Geol., vol. 14, no. 1, Jan.-Feb. 1919, pp. 68-78. Data obtained from leaching of tungsten minerals (scheelite, ferberite, wolframite, and hübnerite); data obtained from precipitating tungsten from solution; writer's interpretations of data.

Production and Import of Tungsten Ores. Automotive Industries, vol. 40, no. 5, Jan. 30, 1919, p. 252. Statistics show slight falling off as compared with two preceding years.

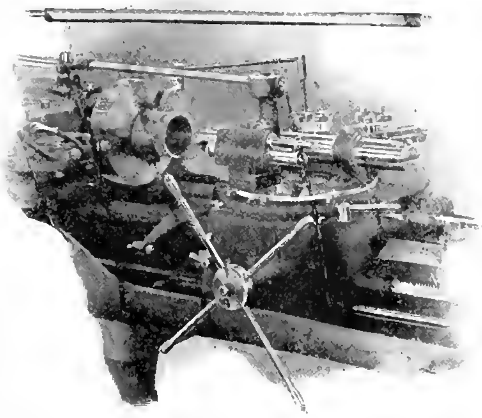
Wolfram Mining in Bolivia, G. F. J. Preumont. Instn. Min. & Metallurgy, bul. 173, Feb. 13, 1919, 9 pp. Occurrences and system of mining.

OIL

Maps and Oil Location

Map Making, R. T. Wells. Natural Gas & Gasoline Jl., vol. 13, no. 2, Feb. 1919, pp. 53-56, 6 figs. Value of maps in oil location and production.

Hartness Automatic Chasing Attachment



The Hartness Chasing Attachment is here shown applied to the Flat Turret Lathe.

This attachment is automatic. The carriage is locked to the bed and the attachment clutched with its positive drive from the work spindle. The threading tool feeds forward at cutting depth under lead screw control until the tool bar strikes a stop. The tool is then withdrawn to clear the work and returned at high speed to the starting point, where it is again fed in to cutting depth and engaged with the lead screw. The work spindle revolves continuously. The only motion required of the operator is that of adjusting the cross sliding head forward a slight amount during the return of the cutter to feed the tool in for the new cut. There is no possibility of overrunning and gouging into a shoulder, no matter how fast the machine is run.

The advantage of this attachment is that it gives engine lathe accuracy to turret lathe threading—and it gives much more than engine lathe speed.

Hartness Automatic Die

Wide Range :: Few Dies :: High Accuracy :: Small Expense

No. 1 Die: Range for standard threads, from $\frac{3}{32}$ inch to $\frac{9}{16}$ inch diameter, any length. Particularly adapted for small hand or automatic screw machine work.

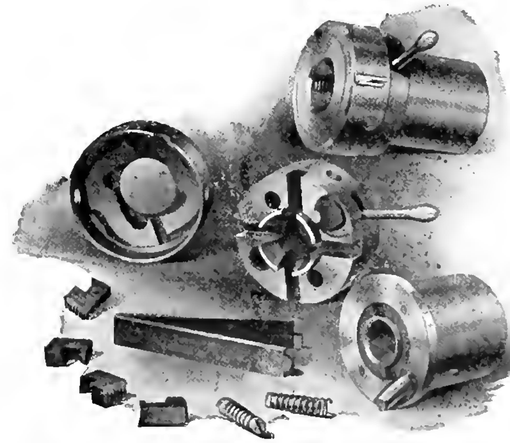
No. 4 Die: Range, $\frac{1}{4}$ inch to $1\frac{1}{4}$ inches diameter. This die is suitable for general turret lathe and screw machine use. It is especially adapted for use in automatic screw machines, owing to the compactness of its design.

No. 6 Die: Range, $\frac{3}{4}$ inch to 2 inches diameter This die is adapted for medium to large work on screw machines and turret lathes, and for the larger sizes of automatic screw machines.

No. 9 Die: Range, $1\frac{3}{4}$ inches to 3 inches diameter. This die is designed for the heaviest turret lathe work. It is provided with six chasers, and has a special double roughing attachment which adapts it particularly to large diameters or coarse pitches.

Any of these dies, even the large No. 9, will thread pitches as fine as 32 per inch on its largest diameter without danger of stripping.

The lead-controlling feature is exclusive with this die. You can cut long threads more accurate in pitch than you will get from the ordinary engine lathe.



The No. 4 Hartness Automatic Die and Its Parts

Mexico

Mexico as Source of Petroleum and Its Products, R. De Golyer. Automotive Industries, vol. 40, no. 8, Feb. 20, 1919, pp. 420-422. Development of Mexican oil fields since 1910.

Oil Refinery

Sidelights on Oil Refinery Practice, E. W. Dean. Automotive Industries, vol. 40, no. 6, Feb. 6, 1919, pp. 315-316. Discussion of four methods of increasing supply of fuels available for use in present types of automotive engines. Paper before Soc. Automotive Engrs. Also in Natural Gas & Gasoline Jl., vol. 13, no. 2, Feb. 1919, pp. 63-64.

Determination of Gasoline in Gas, W. P. Dykema and Roy O. Neal. Chem. Engr., vol. 27, no. 1, Jan. 1919, pp. 5-7. Method of testing natural gas for its gasoline content, evolved at Bartlesville Experimental Station of Bur. of Mines.

United States

Oil in Peace and War, Van H. Manning. Natural Gas & Gasoline Jl., vol. 13, no. 2, Feb. 1919, pp. 73-74. U. S. position in regard to world petroleum situation.

The Unmined Supply of Petroleum in the United States, David White. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 361, 376, and 385. Estimates vary from 5,763,000,000 to 24,500,000,000 bbl.

PRECIOUS MINERALS

Australia

Gold Mining in Western Australia—IV. Thomas Butement. Chem. Eng. & Min. Rev., vol. 10, no. 120, Sept. 1918, pp. 364-368, 2 figs. Present position and outlook of Kalgoorlie mines.

Dredging

Possibilities of Dredging in the Oroville District, California, Charles H. Thurman. Min. & Sci. Press, vol. 118, no. 8, Feb. 22, 1919, pp. 257-258. Reasons why earlier type of dredge did not recover all of the gold.

Gold Ores

Larder Lake Gold Area, Percy E. Hopkins. Can. Min. Jl., vol. 40, no. 5, Feb. 5, 1919, pp. 68-71, 3 figs. Brief history and geological summary of camp.

Lightning River Gold Area and a Remarkable Series of Lava Flows, A. G. Burrows and C. W. Knight. Can. Min. Jl., vol. 40, no. 6, Feb. 12, 1919, pp. 83-86, 3 figs. Account of gold deposits and general geology of district.

Gold Precipitation

Gold Precipitation on Charcoal with an Accelerator, G. D. Reid. Chem. Eng. & Min. Rev., vol. 10, no. 120, Sept. 1918, pp. 374-375, 2 figs. Describes type of box for charcoal preciptation.

Platinum

The Source of Placer Platinum in the Tulameen District of British Columbia, R. M. Macauly. Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, pp. 303-306, 1 fig. Claims that origin of Tulameen platinum is due to magmatic differentiation in peridotile and declares commercial extraction of platinum is doubtful.

Silver Ores

The Smelting and Refining of Cobalt Silver Ore, Sydney B. Wright. Eng. & Min. Jl., vol. 107, no. 6, Feb. 8, 1919, pp. 263-264. Operation at Deloro Reduction Co.'s works of high- and low-grade silver-cobalt ore in lump form, jig and table concentrate, and ore residues.

Statistics

Graphics of Gold and Silver, M. W. von Bernewitz. Min. & Sci. Press, vol. 118, no. 7, Feb. 15, 1919, p. 223. Production of world from 1889-1918.

Gold Production in the British Dominions, William Frecheville. Min. & Sci. Press, vol. 118, no. 7, Feb. 15, 1919, pp. 220-222. Appendix to Incheape Commission's Report on status of gold.

Mineral Production of British Columbia for 1918 Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, pp. 320-322. Official report of gold commissioners and resident engineers of the province.

The Mining and Metallurgy of Cobalt Silver-Ores, R. W. Leonard. Jl. Eng. Inst. Can., vol. 2, no. 2, Feb. 1919, pp. 86-90. Ore treatment in districts of Temiskaming & Northern Ontario Ry.

The Production of Copper, Gold, Lead, Nickel, Silver, Zinc, and Other Metals in Canada During the Calendar Year 1917. Can. Dept. of Mines, no. 497, 71 pp. Report of Chief of Mineral Resources and Statistics.

RARE MINERALS

Rare Metals

Some of the Rarer Metals. Brass World, vol. 15, no. 2, Feb. 1919, pp. 58-59, 1 fig. Characteristics and properties of barium, bismuth, cadmium, calsium, cerium, cobalt, gallium, glucinum, iridium, lanthanum, lithium, osmium and palladium. (To be concluded.)

TIN

Concentration

The Comparison of Concentration Results with Special Reference to the Cornish Method of Concentrating Cassiterite, Edwin Edser. Instn. Min. & Metallurgy, bul. 173, Feb. 13, 1919, 17 pp., 5 figs. Mathematical analysis of ratio of assay of tailings increment to assay of concentrate; tests to determine variation of fractional loss of cassiterite or tin in terms of enrichment ratio.

Slime Treatment

Slime Treatment on Cornish Frames: Supplements, S. J. Truscott. Instn. Min. & Metallurgy, bul. 173, Feb. 13, 1919, 31 pp., 5 figs. Further experiments to determine circumstances in which plane and fluted surfaces were respectively better, the one than the other; and to try policy of rapid enrichment against more usual practice of continued retreatment of concentrate; also, results on fine grinding of both sand residue and original ore.

Tasmania

The Giblin Tin Lode of Tasmania, Cyril W. Gudgeon. Instn. Min. & Metallurgy, bul. 173, Feb. 13, 1919, 12 pp., 2 figs. Situation, early history, and description of deposits.

Metallurgy

ALUMINUM

Aluminum Alloys

Aluminum and Its Alloys (L'aluminium et ses alliages), Walter Rosenhain. Metallurgie, vol. 50, no. 52, Dec. 25, 1918, pp. 1877 and 1879. Their future after the war. Résumé of conference before Roy. Soc. at Exposition of British Scientific Products.

BLAST FURNACES

Bosh Tuyeres

A Few Notes on Bosh Tuyeres, J. Hollings. Iron & Steel Can., vol. 2, no. 1, Feb. 1919, pp. 11-13, 2 figs. Writer's experience in use of bosh tuyeres. Table and sketch illustrate English practice in number, size and position. Paper presented before Iron & Steel Inst.

Blast-Furnace Production

Ferromanganese in Blast Furnace, P. H. Royster. Iron Trade Rev., vol. 64, nos. 6 and 7, Feb. 6 and 13, 1919, pp. 405-407 and 439-443, 3 figs. From Bur. of Mines' report on investigation of 18 blast furnaces producing ferromanganese.

Bung

Furnace Bung Distributes Blast Evenly. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 446-447, 2 figs. Bung frame is provided with an air cylinder that is cast the full length of the top of the bung; cylinder is closed entirely at one end, but at opposite end an opening is provided for air blast.

Chinese Methods

Chinese Blast Furnace Iron Conversion, C. T. Huang. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 125-126. Smelting of native white iron into foundry pig iron.

Design

Progress in Blast Furnace Design, J. G. West. Iron Trade Rev., vol. 64, no. 8, Feb. 20, 1919, pp. 499-505, 12 figs. Changes in adaptation of mechanical construction; modifications in detail of blast-furnace lines. Abstract of paper presented before Am. Iron & Steel Inst.

Slag Action

Influence of Temperance Upon the Action of Slag Upon Refractory Materials, Raymond M. Howe. Chem. & Metallurgical Eng., vol. 20, no. 4, Feb. 15, 1919, pp. 167-168. Experimental data.

COPPER

Bronze

Manganese Bronze, P. E. McKinney. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 421-425. Possibilities of producing manganese bronze without resorting to use of high-grade virgin materials.

Copper-Aluminum Alloys

Constitution and Hardness of Copper-Aluminum Alloys Having High Percentage of Copper (Constitution et dureté des alliages cuivre-aluminium riches en cuivre). Metallurgie, vol. 50, no. 52, Dec. 25, 1918, p. 1881, 1 fig. General type of graphs showing percentage of aluminum against Brinell hardness. (Continuation of serial.)

Copper Melting

Volatilization of Cuprous Chloride on Melting Copper Containing Chlorine, S. Skowronski and K. W. McComas. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 169-179, 1 fig. Experiments are said to have proved that volatilization of cuprous chloride on melting cathode copper takes place almost in its molecular ratio, and that under present copper-refining practice any cuprous chloride present in or on the cathode can be considered for all practical purposes as completely volatilized on melting, and may be the cause of a serious metallurgical loss of copper.

Leaching

First Year of Leaching by the New Cornelia Copper Co., Henry A. Tobelmann and James A. Potter. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 449-495, 7 figs. Process adopted consisted of leaching crushed ore 8 days by counter-current system and upward circulation, using sulphuric acid and ferric sulphate; reduction by sulphur-dioxide gas of ferric iron in neutral solutions from leaching tanks; electrolytic deposition of copper from reduced solution; and recovery of copper from discharged neutral solution as cement copper precipitated on iron. Numerical results are quoted.

Lead in Brass

Notes on the Rapid Estimation of Lead in Brass and Alloys, G. H. Hodgson. Chem. News, vol. 118, no. 3067, Jan. 24, 1919, pp. 37-38. Two methods are given, one gravimetric and one volumetric.

FERROALLOYS

Ferroalloys

Ferro-Metallic Alloys (Les alliages ferro-métalliques), Jean Escard. Revue Générale des Sciences, vol. 29, no. 23, Dec. 15, 1918, pp. 673-680, 3 figs. Manufacture of ferrochromium, ferrosilicon and ferromanganese. (To be continued.)

Production of Ferromanganese in the Blast Furnace, P. H. Royster. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 367-378, 3 figs. Operating data in ferromanganese practice; average practice for ferromanganese furnace and for iron furnace; calculated slag loss; stack loss. From report of research under joint auspices of U. S. Bur. of Mines and Nat. Research Council.

FLOTATION

Galena

The Flotation of Galena at the Central Mine, Broken Hill, R. J. Harvey. Min. & Sci. Press, vol. 118, no. 5, Feb. 1, 1919, pp. 149-154, 7 figs. Selective flotation of complex silver-lead-zinc sulphide associated in the main with quartz, rhodonite, rhodochrosite, and some garnet-sandstone. Paper before Instn. Min. & Metallurgy.

Lead Ores

Flotation of Oxidized Ores of Lead, Glenn L. Allen. Chem. & Metallurgical Eng., vol. 20, no. 4, Feb. 15, 1919, pp. 169-175, 1 fig. Process of sulphidizing ores such as cerussite, wulfenite and cerargyrite.

IRON AND STEEL

Aging Break

A Volute Aging Break, Henry M. Howe and Edward C. Groesbeck. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 181-182, 2 figs. Views of volute which developed spontaneously in a hardened and tempered steel helmet between 19 and 38 days after it had been tested ballistically.

Bessemer Process, Acid

Present American Acid Bessemer Process, Richard S. McCaffery. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 140-142. Reversibility of manganese oxidation reaction; eliminating "spitting" by temperature control during blow.

Blast Furnaces

See preceding column.

Bluing Steel

Bluing Steel, W. B. Greenleaf. Mech. World, vol. 64, no. 1668, Dec. 20, 1918, pp. 291-292, 2 figs. Saltpeter process.

Converter Casting

Converter Steel Casting Practice, Charles M. Campbell. Proc. Steel Treating Research Soc., vol. 1, no. 10, July 1918, pp. 7-20, 15 figs. Description of steel foundry equipped with two cupolas, three 2-ton converters and producing an average of 12 heats per day. Suggestions in regard to molding, casting annealing and heat-treating.

Electric Smelting

Electric Smelting of Iron Ores in British Columbia, Alfred Stansfield. Iron & Steel Can., vol. 2, no. 1, Feb. 1919, pp. 4-10. Report of investigation to determine commercial

possibility. Swedish type of furnace is recommended as most economical for permanent plant, and open pit furnace is suggested as best for temporary plant.

Dr. Stansfield's Report on Electric Smelting of B. C. Iron Ores. Can. Min. Jl., vol. 40, no. 4, Jan. 29, 1919, pp. 54-56. Finds that while process is metallurgically feasible, nevertheless, under present conditions and prices for electric energy, its application would not be practical.

Electric Smelting of Domestic Manganese Ores, H. W. Gillett and C. E. Williams. Dept. of Interior, Bur. of Mines, War Minerals Investigations Series, no. 10, Dec. 1918, 48 pp. Tests to investigate whether electric smelting of manganiferous slags and low grade domestic ores is likely to be profitable at times of normal costs and prices are said to have demonstrated that such smelting is metallurgically possible but practicable only in times of high prices.

Electric Steel

Making Electric Steel for Ball Bearings, Arthur V. Farr. Iron Trade Rev., vol. 44, no. 3, Jan. 16, 1919, pp. 211-215, 12 figs. Reviews method of manufacture and calls attention to qualities of steel produced in electric furnace.

The Metallurgy of Electric Furnace Steel Processes, L. B. Lindemuth. Jl. Engrs. Club, Phila., vol. 35-12, no. 169, Dec. 1918, pp. 544-549. History; crucible process; open hearth; electric furnace; duplex and triplex processes; comparison between metallurgical features of electric-furnace process and those of the open-hearth and crucible processes.

Flaky Steel

Microstructural Features of Flaky Steel, Henry S. Rawdon. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 183-201, 27 figs. Summarizes characteristic features of defective steel of flaky type as found from laboratory study of numerous specimens, and aims to show conditions within metal that are favorable to occurrence of this type of defect.

Ingot-Production Statistics

Production of Ingots and Rolled Products. Iron Age, vol. 103, no. 8, Feb. 20, 1919, pp. 497-500. Statistics prepared by American Iron and Steel Institute show new record for steel and some finished forms in 1917.

Iron and Steel Trades

Iron and Steel. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 17. How iron and steel trades have emerged from war.

Production of Steel Ingots and Castings, Finished Rolled Iron and Steel in 1917. Iron Trade Rev., vol. 64, no. 8, Feb. 20, 1919, pp. 520-521. Statistical tables.

The Production of Iron and Steel in Canada During the Calendar Year 1917, John McLelsh. Can. Dept. of Mines, no. 498, 32 pp. Report of Chief of Division of Mineral Resources and Statistics.

Iron-Carbon-Chromium Alloys

On the Structure of Iron-Carbon-Chromium Alloys, Takejirô Murakami. Sci. Reports Tôhoku Imperial Univ., First Series, vol. 7, no. 3, Dec. 1918, pp. 217-276, 124 figs. Report of experimental investigation of alloys containing different amounts of iron, carbon, and chromium with particular reference to structural constitution, changes during heating and cooling, and self-hardening properties. Materials tested were Swedish iron, four different steels, white cast iron, ferrochromium and metallic chromium.

Japanese Iron Industry

The Japanese Iron & Steel Industry. Blast Furnace, vol. 7, no. 2, Feb. 1919, pp. 89-95. Report upon conditions in Manchuria and Korea and upon possibility of Japanese future independence in production of iron and steel.

Manganese Alloys

Manganese Alloys in Open Hearth Practice, Samuel L. Hoyt. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 142-146. Recommendations for utilization of domestic alloys; molten spiegel mixture practice; use of manganese-silicon alloys in acid practice; electric furnace practice.

Open-Hearth Furnaces

Principles of Open Hearth Furnace Design—III, Charles H. F. Bagley. Blast Furnace, vol. 7, no. 2, Feb. 1919, pp. 111-113, 1 fig. Further considerations of furnace dimensions based on gas port area and hearth area per ton of steel capacity.

Use of Manganese Alloys in Open-Hearth Practice, Samuel L. Hoyt. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 277-289. It is advanced that there are three practices for utilizing our domestic alloys in open-hearth practice: Use of molten spiegel mixture for deoxidation and recarburation; practice of melting and refining steel bath so as to secure 0.3 per cent manganese alloys containing silicon; use of manganese alloys containing silicon. From report of research under joint auspices of U. S. Bur. of Mines and Nat. Research Council.

Water-Cooled Equipment for Open-Hearth Steel Furnaces, Wm. C. Coffin. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 497-515, 12 figs. Suggests that water-cooling devices for open-hearth steel furnaces should follow lines used in iron blast furnaces; several devices are illustrated.

Refractories

See Refractories, under Mechanical Engineering.

Rolling Mills

See Mechanical Processes (Rolling Mills), under Mechanical Engineering.

Tool Steel

New Tool Steel Developed by Research. Iron Trade Rev., vol. 64, no. 9, Feb. 27, 1919, pp. 576-577, 4 figs. Made of alloys and arranged within critical zones in order to make martensite predominant structure. Said not to diminish in efficiency by overheating.

Transformations in Steel

Effect of Rate of Temperature Change on Transformations in an Alloy Steel, H. Scott. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 157-167, 7 figs. Previous investigators have laid particular stress on variation of maximum temperature, rate remaining constant, while variation of rate, maximum temperature remaining constant has received little attention. Writer has applied latter method to investigation of an alloy steel and attempts to correlate results of that method with those of the former and to establish relations of several phenomena observed.

See also MINING ENGINEERING, Major Industrial Materials (Manganese); ELECTRICAL ENGINEERING, Furnaces (Steel Furnaces).

NON-FERROUS METALS

Non-Ferrous Metals

Non-Ferrous Metals. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 18. Advances made in their manufacture during recent years.

OCCLUDED GASES

Steel

Investigation of Gases Occluded in Steel, Thomas Baker. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 156-157 and 163. Experiments to determine composition and volume of occluded gases and their effect upon physical properties of metal, relation between temperature at evolution of gas and electrical point.

ZINC, LEAD AND TIN

Conservation

Metallurgical Work of Bureau of Standards, G. K. Burgess. Blast Furnace, vol. 7, no. 3, Mar. 1919, pp. 130-131, 2 figs. Review of research work concerning welding and tin conservation. (To be continued.)

Electric Furnace for Tin

Electrometallurgy of Tin in Electric Furnace (L'électrométallurgie de l'étain au four électrique), Jean Escard. Industrie Electrique, vol. 27, no. 635, Dec. 10, 1918, pp. 444-448. Treatment of minerals; furnaces; recovery of lead; extraction of tin from industrial waste.

Zinc

Zinc Smelting in India, T. R. Wynne. Eng. & Min. Jl., vol. 107, no. 8, Feb. 22, 1919, pp. 356-358. Possibilities of zinc smelting in India; investigation of Burma ores; industrial development in India. Report of chairman at general meeting of Burma Corporation.

HYDROMETALLURGY

Terminology

Defining "Tailings" and "Residues," A. W. Allen. Eng. & Min. Jl., vol. 107, no. 7, Feb. 15, 1919, p. 317. Submits definitions. Third article of series on standardization of terms used in hydrometallurgical operations.

Aeronautics

AEROPLANE PARTS

Cooling System

The Loomis Cooling System for Aircraft. Mech. Eng., vol. 41, no. 3, Mar. 1919, pp. 255-256, 3 figs. System embodies nose radiator, adjustable booster and expansion tank with positive ejection.

Radiators

The Aeronautical Radiator, S. R. Swenson. Aerial Age, vol. 8, no. 25, Mar. 3, 1919, pp. 1256-1261 and 1286, 14 figs. Types and designs in general. Study of coefficients; the nose radiator.

AEROSTATICS

Airship Operations

British Airship Development and Operations. Aviation, vol. 5, no. 12, Jan. 15, 1919, pp. 758-759, 1 fig. Figures relative to man power required for operating airships, casualties per flight mileage, and non-flying days.

Commercial Airships

Airships for Commercial Purposes. Flight, vol. 11, no. 5, Jan. 30, 1919, pp. 144-148. Relative advantages of airships and aeroplanes; development and potentialities of rigid airships and aeroplanes; commercial considerations relating to airships. Officially issued by Air Ministry.

The report of the Civil Aerial Transport Committee. Flight, vol. 11, no. 4, Jan. 23, 1919, pp. 119-125. Main or terminal aerodrome; intermediate landing grounded; airship for commercial purposes; correspondence relating to fog on the Newfoundland coast. (Continued from p. 27.)

Dirigibles for Transport

Value of Dirigibles for Aerial Transport, Henry Woodhouse. Flying, vol. 8, no. 2, Mar. 1919, pp. 137-143, 7 figs. Relative advantages of airships and airplanes; progress in heavier-than-air and lighter-than-air machines 1914-1918; technical advantages in designs of airships. From report of Civil Aerial Transport Committee.

Military Balloons

Military Aerostatics, H. K. Black. Aerial Age, vol. 8, no. 24, Feb. 24, 1919, pp. 1166-1167, 4 figs. Free ballooning. (Continuation of serial.)

AIRCRAFT PERSONNEL

Flying Sickness

Flying Sickness, Martin Flack. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 21-22, 1 fig. Record of experiences of aviators and tests.

Tests for Flyers

Medical Aspects of Aviation, L. E. Stamm. Aeronautics, vol. 16, no. 275, Jan. 22, 1919, pp. 111-113, 3 figs. Physical and mental requisites for aviation work. (To be continued.) Paper before Roy. Aeronautical Soc.

The Wear and Tear of Flying, T. S. Rippon. Flight, vol. 11, no. 4, Jan. 23, 1919, pp. 108-109. Methods used by French physicians in examining pilots; American tests.

APPLICATIONS

Aerial Ports

Organization of Aerial Ports, Gino Bastoji. Aviation, vol. 6, no. 1, Feb. 1, 1919, p. 35. Future developments. From Rivista del Transporti Aerei.

Commercial Aviation

Commercial Aviation in the Light of War Experience, F. H. Sykes. Aeronautics, vol. 16, no. 274, Jan. 15, 1919, pp. 81-83. Concerning safety, base and repair facilities, operation of flying roads, meteorology and aerodrome management. Abstract of lecture before Lond. Chamber of Commerce. Also in Flight, vol. 11, no. 3, Jan. 16, 1919, pp. 84-88.

Mail Service

Aerial Mail in the United States and Abroad, Otto Praeger. Flying, vol. 8, no. 2, Mar. 1919, pp. 144-147 and 174-177, 5 figs. Programs proposed and in operation; equipment; coöperation in Post Office Dept. and U. S. Army.

The World's Aerial Mail and Passenger Services. Aviation, vol. 5, no. 12, Jan. 15, 1919, p. 755. Operating and projected services.

Passenger Traffic

Aerial Travel for Reconstruction, G. Holt Thomas. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, p. 12. Visualization of transaction of business through instrumentality of aerial navigation.

Patrol Work, Forest

Use of Airplanes in Forest Patrol Work, Henry S. Graves. Aviation, vol. 5, no. 12, Jan. 15, 1919, pp. 754-755. Present service.

Regulation

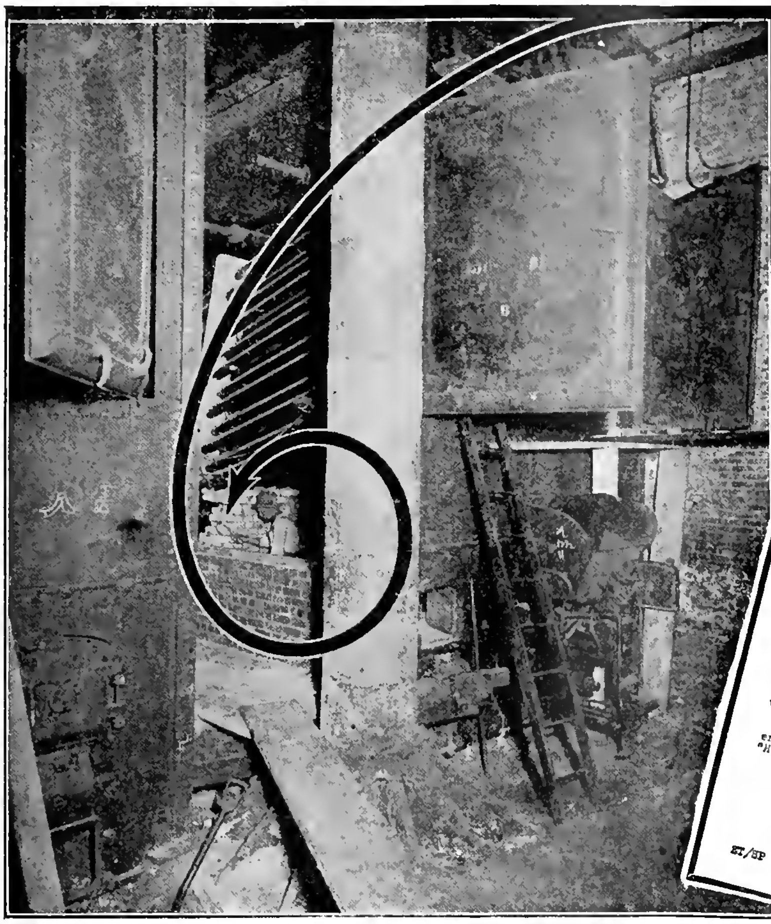
Future Air Traffic and Necessary Regulations to Govern Same, Alan R. Hawley. Flying, vol. 8, no. 2, Mar. 1919, pp. 149-154, 6 figs. Problem of utilizing military airplanes and employing demobilized aviators.

To Regulate Aerial Navigation, Henry Woodhouse. Flying, vol. 8, no. 1, Feb. 1919, pp. 33-42, 70 and 72, 15 figs. Study by British Aerial Transport Committee and Act this committee has drafted for regulation of aerial navigation.

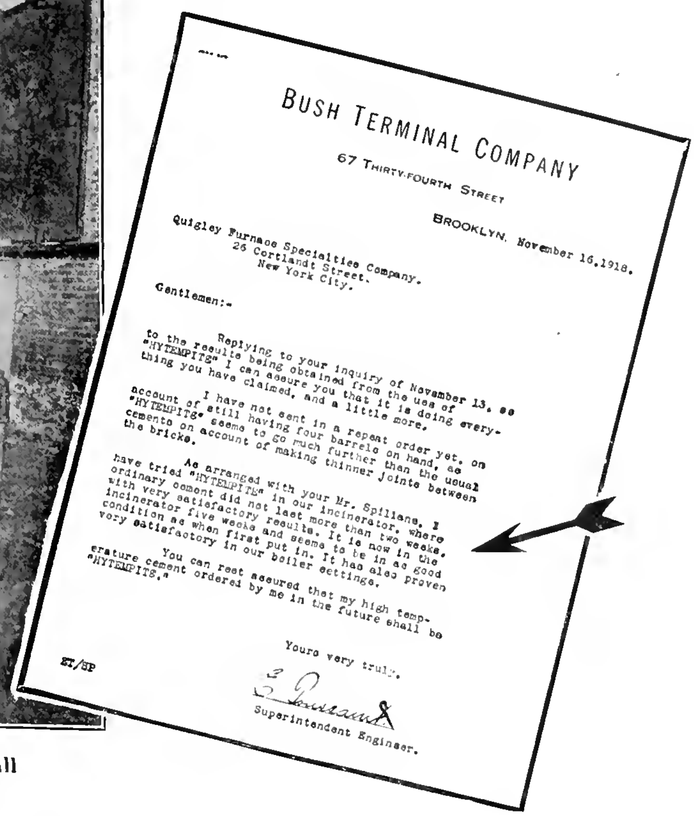
Safety

The Reliability of Aircraft Travel, Mervyn O'Gorman. Aeronautics, vol. 16, no. 272, Jan.

Deep in the Vitals of your Boiler Settings or Furnaces is where you need a strong, thin joint to bond your fire brick; a joint that is as strong as the brick itself and has the same coefficient of expansion.



Stoker-Fired Boiler Setting—Bonding the Bridge Wall



BUSH TERMINAL COMPANY

67 THIRTY-FOURTH STREET

BROOKLYN, November 16, 1918.

Quigley Furnace Specialties Company,
26 Cortlandt Street,
New York City.

Gentlemen:-

Replying to your inquiry of November 13, as to the results being obtained from the use of "HYTEMPITE" I can assure you that it is doing everything you have claimed, and a little more.

I have not sent in a repeat order yet, on account of still having four barrels on hand, as "HYTEMPITE" seems to go much further than the usual cements on account of making thinner joints between the bricks.

As arranged with your Mr. Spillane, I have tried "HYTEMPITE" in our incinerator, where ordinary cement did not last more than two weeks, with very satisfactory results. It is now in the incinerator five weeks and seems to be in as good condition as when first put in. It has also proven very satisfactory in our boiler settings.

You can rest assured that my high temperature cement ordered by me in the future shall be "HYTEMPITE."

Yours very truly,

Superintendent Engineer.

ET/SP

This mason is using

HYTEMPITE

Reg U. S. Pat. Off.

HIGH TEMPERATURE FIRE BRICK CEMENT

Because

HYTEMPITE makes the walls gas and air tight. It does not disintegrate, and prevents gases of combustion from entering the joints or leakage of air through the wall.

HYTEMPITE does not depend on heat for its adhesive qualities. It will air-set and the bond will retain its strength under all temperature conditions encountered.

HYTEMPITE will increase the life of boiler settings:—vouched for by hundreds of testimonials.

QUIGLEY FURNACE SPECIALTIES CO.

Topographic Surveying by Aerial Photography, Arthur Brock, Jr., and L. J. R. Holst. Aviation, ol. 6, no. 2, Feb. 15, 1919, pp. 75-78, 9 figs. Use of aerial photography to making contour maps. Inspection of aerial negatives and interpretation of direction by means of them.

Transcontinental Flight

Aerial Transportation, Evan J. David. Flying, vol. 8, no. 1, Feb. 1919, pp. 64, 66, 75-76, and 78, 2 figs. Review of progress. Squadron of four Army training planes is reported to have completed transcontinental flight.

DESIGN

Aeroplane Design

Aeroplane and Seaplane Engineering, H. C. Richardson. Aerial Age, vol. 8, no. 24, Feb. 24, 1919, pp. 1171-1173, 1180 and 1182-1183, 2 figs. Paper presented before Soc. Automotive Engrs.

Report of the U. S. National Advisory Committee for Aeronautics. Aeronautics, vol. 16, no. 275, Jan. 22, 1919, pp. 116-117. Activities of Committee between Oct. 4, 1917, and Oct. 10, 1918. (To be continued.)

German Design

Trend of German Airplane Design. Automotive Industries, vol. 40, no. 5, Jan. 30, 1919, pp. 262-265, 3 figs. Summary of features of captured enemy machines. Issued by Technical Department, Aircraft Production, Ministry of Munitions.

Incidence Wires

Incidence Wires in the Strength Calculations of Wing Structures, John Case. Aeronautics, vol. 16, no. 273, Jan. 8, 1919, pp. 46-51, 4 figs. Discusses accuracy of method outlined in preceding installment. (Continued from vol. 15, p. 607.)

Inspection

Some Avoidable Dangers in Airplane Construction, Walter O. Adams. Am. Mach., vol. 50, no. 8, Feb. 20, 1919, pp. 365-366. Points out some avoidable dangers and suggests standardized inspection for elimination of defective small parts.

Research

Full Scale Aeroplane Experiments, W. S. Farren. Aeronautics, vol. 16, nos. 273 and 274, Jan. 8 and 15, pp. 53-56 and 84-86. Scope of experimental research undertaken by Roy. Aircraft establishment. Abstract of paper before Roy. Aeronautical Soc.

Rigging

Rigging, F. W. Halliwell. Flight, vol. 11, nos. 4, 5 and 6, Jan. 23 and 30, Feb. 6, 1919, pp. 107, 132-134 and 176-179, 18 figs. Manufacturing particulars in construction and erection.

Struts

Design of Airplane Struts, W. H. Barling and H. A. Webb. Aviation, vol. 6, no. 2, Feb. 15, 1919, pp. 79 and 82-83, 6 figs. Effect of tapering on strength. Paper before Roy. Aeronautical Soc.

The Spacing of Interplane Struts, John Case. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 18-20, 15 figs. Computations for various types and cases.

Wing Spar Stresses

Wing Spar Stresses, H. A. Webb and H. H. Thorne. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 8-11, 8 figs. Formulæ and bending-moment diagrams.

ENGINES

Aeromarine Engine

The Aeromarine Type L 6-Cylinder Aero Motor. Aerial Age, vol. 8, no. 24, Feb. 24, 1919, pp. 1164-1165, 4 figs. Describes motor designed for training and sporting machines.

American Engines

American Aero Engines, G. Douglas Wardrop. Aerial Age, vol. 8, no. 25, Mar. 3, 1919, pp. 1242-1251 and 1283, 10 figs. General data of Liberty 12, King-Bugatti, Curtis K-6 and K-12, Hispano-Suiza, Duesenberg model H, Lawrence 60-hp. air-cooled engine, Union 6-cylinder aeromotor, Knox 12, Hall-Scott A-8, and 80-hp. Le Rhone.

Carburetors

A New Principle in Carburation. Aerial Age, vol. 8, no. 25, Mar. 3, 1919, p. 1223, 2 figs. Brown carburetor said to operate automatically at all speeds.

Characteristics

Characteristics of Leading Aero Engines. Aerial Age, vol. 8, no. 25, Mar. 3, 1919, pp. 1252-1254. Tables of dimensions and data.

Curtiss

The Curtiss Model K-6 Aircraft Engine. Aviation, vol. 6, no. 2, Feb. 15, 1919, pp. 83-84, 1 fig. General design.

The Curtiss Model K-6 and K-12 Aero Motors. Aerial Age, vol. 8, no. 21, Feb. 3, 1919, pp. 1030-1034, 10 figs. Form of construction adopted gives minimum center distance between cylinders, together with placing of accessories and accessibility of various parts for inspection or overhauling.

Design

The Design of Aeroplane Engines—XV, John Wallace. Aeronautics, vol. 16, no. 274, Jan. 15, 1919, pp. 77-80, 6 figs. Cam design; choice of cam; calculations for profile; process of laying out cam; valve-lift diagram; gas velocity; cams for radial engines. (Continuation of serial.)

Duesenberg

Duesenberg Sixteen-cylinder Aircraft Engine. Automotive Industries, vol. 40, no. 4, Jan. 23, pp. 214-218, 13 figs. Weight 1250 lb.; 700 hp. on direct drive and 800 on geared. Said to be the largest aeroplane engine produced in U. S.

Liberty

Liberty Engine Tests. Mech. Eng., vol. 41, no. 3, Mar. 1919, pp. 249-253 and 295, 8 figs. Authentic data on performance tests of the standard high-compression army-type 12-cylinder Liberty engine.

The Liberty Aircraft Engine, J. G. Vincent. Automotive Industries, vol. 40, nos. 6 and 7, Feb. 6 and 13, 1919, pp. 323-327 and 378-385, 8 figs. Feb. 6: Chronological history of development, with remarks on incidents and military requirements that affected its design. Paper before Soc. Automotive Engineers. Feb. 13: Discussion of various features of design, with reasons for their adoption; performance of planes equipped with engine.

Magnetos

Standardized Magnetos for Aircraft Engines. Aviation, vol. 6, no. 1, Feb. 1, 1919, p. 37, 1 fig. Features of Dixie types.

Napier

Napier "Lion" Aero Engine, G. Douglas Wardrop. Aerial Age, vol. 8, no. 25, Mar. 3, 1919, pp. 1262-1264, 7 figs. English 12-cylinder model used by Capt. Lang in establishing world's altitude record of 30,500 ft.

Rotary

The 80-hp. Le Rhone Airplane Engine. Aviation, vol. 6, no. 2, Feb. 15, 1919, pp. 70-73, 8 figs. Principles of rotary engine; features of design; performance graph; specifications.

Stresses

The Design of Aeroplane Engines—XVI, John Wallace. Aeronautics, vol. 16, no. 275, Jan. 22, 1919, pp. 102-105, 10 figs. Inertia forces; loads on cam and tappet; stresses in camshaft; torsion of camshaft.

Thermal Efficiency

Importance of High Thermal Efficiency in Aeroplane Engine Design and Construction, Charles W. Burrage. Aerial Age, vol. 8, no. 24, Feb. 24, 1919, pp. 1168-1170, 3 figs. Graph showing difference in characteristics of various aeroplane power plants.

Valves

Valve Dispositions in High-Speed Aircraft Engines, John Wallace. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 34-36, 5 figs. Computations of valve areas in theoretical engine under assumed conditions.

INSTRUMENTS

Ignition Interrupter

Douglas Automatic Airplane Ignition Interrupter. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 372-373, 2 figs. Safety device for stopping engine when propeller breaks or other breakage occurs.

MATERIALS OF CONSTRUCTION

Coatings for Boats

Tests of Moisture and Water Resistance of Various Coatings on Small Boat Construction, Henry A. Gardner. Inst. Indus. Research, Washington, D. C., 10 pp., 3 figs. Following coatings conforming to aeronautical specifications of Navy Dept. were tested: Raw linseed oil; acetate dope; oil graphite; spar varnish; and enamel.

Fabrics

Properties of Aeroplane Fabrics, E. Dean Walen. Aeronautics, vol. 16, no. 274, Jan. 15, 1919, pp. 87-90, 8 figs. Methods used by Bur. of Standards in developing a cotton fabric as a substitute for linen for aeroplane wing coverings.

MILITARY AIRCRAFT

Airships, British

The Role of British Airships in the War, W. Lockwood Marsh. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 13-17, 8 figs. Various types and their uses; war incidents.

War Department, U. S.

Aeronautics, George O. Squier. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 33-35. Information on work done by Aeronautics Branch of War Dept.

MODELS

Air Screw

Model Aeroplanes—XX, F. J. Camm. Aeronautics, vol. 16, no. 275, Jan. 22, 1919, p. 109, 4 figs. Designing the air screw.

Motor

Model Aeroplane Building as a Step to Aeronautical Engineering. Aerial Age, vol. 8, no. 24, Feb. 24, 1919, p. 1177, 2 figs. Illustrations of redesigned Ford motor.

Performance

Model Aeroplane Building as a Step to Aeronautical Engineering. Aerial Age, vol. 8, no. 21, Feb. 3, 1919, p. 1045, 1 fig. Checking possible performance of machine. (Continuation of serial.)

Power

Model Aeroplane Building as a Step to Aeronautical Engineering. Aerial Age, vol. 8, no. 25, Mar. 3, 1919, p. 1269, 2 figs. Minimum power required for flying.

PLANES

Armored Planes

Armored Aeroplanes, H. A. Webb. Aeronautics, vol. 16, no. 274, Jan. 15, 1919, pp. 74-76, 6 figs. Comparison of vulnerabilities of square and round bodies.

The Fokkers-Junkers Armored Biplane. Aviation, vol. 6, no. 1, Feb. 1, 1919, p. 36, 1 fig. Wing construction.

Bristol

The "Bristol" Machines. Flight, vol. 11, no. 4, Jan. 23, 1919, pp. 100-105, 25 figs. Types developed of monoplane, biplane and triplane design.

Curtiss

The Curtiss Type 18-2 Triplane. Aviation, vol. 6, no. 2, Feb. 15, 1919, pp. 74-75, 2 figs. Dimensions and weights.

De Haviland

The De Haviland, or "Airco," Machines. Flight, vol. 11, no. 2, Jan. 9, 1919, pp. 36-45, 40 figs. Development of this type and features of ten models designed.

The Enclosed D. H. 4. Flight, vol. 11, no. 4, Jan. 23, 1919, p. 111, 2 figs. Views of totally enclosed two-passenger aerial limousine.

Helicopters

The Helicopter, M. A. S. Riach. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 23-25. Problem of direct-lift flying machine in light of modern airscrew analysis.

Loening

Description of the Loening Monoplane. Aviation, vol. 5, no. 12, Jan. 15, 1919, pp. 759-762, 5 figs. Construction, engine installation and performance.

Martin

The Martin K-III. Scout. Aeronautics, vol. 16, no. 275, Jan. 22, 1919, pp. 106-108, 4 figs. Details and performance. From Aerial Age. Biplane has wing span of 18 ft., weighs 350 lb. and is equipped with 40-hp. A.B.C. engine.

Sopwith

The Sopwith Machines. Flight, vol. 11, no. 6, Feb. 6, 1919, pp. 163-174, 56 figs. Stages in evolution; classification, dimensions, weights of the 21 types produced.

Standard

The Standard Model E-4 Mail Aeroplane. Aerial Age, vol. 8, no. 21, Feb. 3, 1919, pp. 1036-1037 and 1034, 7 figs. General dimensions, weights and details.

Sundstedt

Airplanes for the Transatlantic Flight. Sci. Am., vol. 120, no. 9, Mar. 1, 1919, pp. 202 and 215, 4 figs. Sundstedt biplane. Upper plane has a spread of 100 ft., lower plane 71½ ft.; equipped with 2 Hall-Scott engines rated at 220 hp. each; weight 10,000 lb.; estimated speed 80 mi. per hr.

Rex Steel Roller Chain of the Chabelco type used for carrying the baskets of Rex Traveling Water Screens.

You can secure Standard Rex Sprocket Chain of any size or type, either through distributors or direct, for every transmission and conveyor need.

Numerous Rex Traveling Water Screen installations have proven to many American power plants that intake troubles need not be accepted as necessary evils.

Clean water and continuous operation can be assured at a very low cost per year by Rex Traveling Water Screens.

Send For This Rex Catalog

Our catalog No. 85 describes and pictures the details of design and operation of the standardized type of Rex Traveling Water Screens.

Every factory, plant and mill superintendent and engineer can gain by a study of its pages.

Send for it today.

It presents in detail the connection between your intake and your production.

If your problems are those of public utilities companies, you can learn what others have done to solve them.

If you are in a steel mill, it will pay you especially to send for this booklet today.

Many of the shut-downs still accepted as necessary evils in steel plants can be prevented by a proper solution of the intake problem.

The best protection to bosh plates and tuyere openings is an adequate supply of *clean* water.

Particularly those plants, whatever their product, whose water supply is endangered in winter by slush-ice and in spring by floods should write for Catalog 85 of Rex Traveling Water Screens.

CHAIN BELT COMPANY, MILWAUKEE

734 PARK STREET

New York Chicago Philadelphia Pittsburgh

REX TRAVELING WATER SCREENS

Rex Chains, Rex Concrete Mixers,
Rex Sprockets, Rex Elevators and Conveyors

The Sundstedt-Hannevig Seaplane. Aerial Age, vol. 8, no. 24, Feb. 24, 1919, pp. 1162-1163 and 1183, 5 figs. Designed for long-distance flying over sea.

PRODUCTION

Le Pere

Production of Le Père Planes Was Well Started, J. Edward Schipper. Automotive Industries, vol. 40, no. 6, Feb. 6, 1919, pp. 303-304, 4 figs. Manufacturing details.

See also ORGANIZATION AND MANAGEMENT, *Education (Training Department, Aircraft Factory).*

PROPELLERS

Calculator for Propellers

A Convenient Calculator for Propellers, E. P. Klog. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 31-33, 3 figs. Chart intended to simplify theoretical work on propeller performance by blade-element method.

Torque

Propeller Torque, J. Morris. Aeronautics, vol. 16, no. 273, Jan. 8, 1919, p. 52, 1 fig. How it arises and its action in the case of both geared and ungeared engines.

SPECIFICATIONS, AEROPLANE

Seaplanes

Navy Issues Seaplane Specifications. Aviation, vol. 6, no. 2, Feb. 15, 1919, pp. 73-74. Schedule for furnishing plans, supervisory assistance and construction of seaplanes.

TRANSATLANTIC FLIGHT

Airship vs. Aeroplane

Possibilities of an Atlantic Air Line. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 41-42. Airships versus airplanes.

VARIA

Metric System

The Metric System and the Aeronautical Industry, David Scott. Aeronautics, vol. 16, no. 272, Jan. 1, 1919, pp. 26-27. Plea for adoption of metric system by Great Britain.

National Advisory Committee

National Advisory Committee Report. Aviation, vol. 5, no. 12, Jan. 15, 1919, pp. 750-753. Recommendations regarding future development of American aeronautics; power plants for aircraft; materials for aircraft.

Progress in 1918

Aeronautics. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 14-15. Survey of developments in 1918.

Aeronautics in the United States, 1918, George O. Squier. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 2, Feb. 1919, pp. 53-114, 17 figs. Review of development of military aeronautics in United States up to date of armistice.

Wind Velocity, Determination of

Determination of Wind Velocity and Direction by Means of Sound Waves (Sur une méthode de détermination de la vitesse et de la direction des vents, par temps couvert, à l'aide de sondages par le son), M. Bourgeois. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 22, Nov. 25, 1918, pp. 769-772. Balloon carries fireworks timed to explode at regular intervals; motion of balloon is recorded at each explosion, which serves to compute height.

Marine Engineering

AUXILIARY MACHINERY

Lifting Gear

Marine Steam Turbine Lifting Gear. Mech. World, vol. 65, nos. 1671 and 1673, Jan. 10 and 24, 1919, pp. 18-19 and 43, 5 figs. Brief outline and discussion of various types, giving general method of calculating proportions of principal parts. First and second installments. (To be continued.)

Oil Filter

An Efficient Oil Filter for Marine Installations. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 130-131, 3 figs. Combination batch and continuous oil filter of Paterson marine type.

SHIPS

American Types

American Shipbuilding Practice. Shipbuilding & Shipping Rec., vol. 13, no. 3, Jan. 16, 1919, pp. 63-66, 2 figs. Types of vessels adopted by Submarine Boat Corporation; organization and operation of Hog Island and arrangement of the yards.

American Shipbuilding

The Early History of American Shipbuilding, W. A. Dobson. Jl. Engrs. Club Phila., vol. 35-10, no. 167, Oct. 1918, pp. 455-466, 9 figs. Review of history and practice of shipbuilding in U. S. prior to 1880 as compiled from memoirs of C. M. Cramp, the report by Henry Hall, and the writer's personal experience.

Concrete Ships

Concrete Ships VI. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 38. Notes on yards at Thornaby-on-Tees, Amble, Whitby, Sunderlan, Granton and Faversham, where concrete ships are being built.

A Composite System of Reinforced Concrete Ship Construction, A. S. Holmes. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 116-117, 2 figs. System employs a combination of timber, concrete and reinforcing metal.

Ireland's First Concrete Ship. Shipbuilding & Shipping Rec., vol. 13, no. 2, Jan. 9, 1919, p. 42, 1 fig. Account of her launching; general dimensions.

Efficiency

The Economic Efficiency of Merchant Ships, Alexander Urwin. Shipbuilding & Shipping Rec., vol. 13, no. 3, Jan. 16, 1919, pp. 72-74. Table showing factors in a deadweight cargo carrier which operate upon each other and decide efficiency of vessel.

European Shipbuilding

European Marine Notes. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 114-115. Model British fabricated ship; concrete barges; German shipping in the war.

Fabricated Vessels

The "N" or Fabricated Vessels, Engineering, vol. 107, no. 2768, Jan. 17, 1919, pp. 69-71, 6 figs. Discussion of "National" standard vessels built according to "d'Eyncourt-Graham" system.

Ford Methods

Ford Methods in Ship Manufacture, Fred E. Rogers. Indus. Man., vol. 57, no. 3, March 1919, pp. 190-197, 10 figs. Division and subdivision of the erecting operations. Third article.

Freighter

SS. "Westerner." Shipbuilding & Shipping Rec., vol. 13, no. 1, Jan. 2, 1919, pp. 8-9, 2 figs. Principal dimensions, plans and details of cargo steamer of 8800 tons d.w. on 24 ft. 1 in. draft. Built by Emergency Fleet Corporation.

Machinery and Pipe Arrangement

Machinery and Pipe Arrangement, C. C. Pounder. Mech. World, vols. 64 and 65, nos. 1668, 1672 and 1674, Dec. 20, 1918, Jan. 17 and 31, 1919, pp. 295, 30 and 55, 11 figs. Typical location in vessels built to Board of Trade requirements. Tenth to twelfth installments. (Continuation of serial.)

Motorships

Motor-Driven Tanker "Hamlet." Shipbuilding & Shipping Rec., vol. 13, no. 2, Jan. 9, 1919, pp. 36-41, 8 figs. 10,055 tons d.w. on 24 ft. 7 in. draft. Propelling machinery consists of two Polar Diesel engines.

Splendid Record of Wooden Motorship. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 94-95, 2 figs. Account of travel of "Libby Maine" in voyage through arctic waters.

Propelling Machinery

Notes on Trial Trips, S. H. Cornell. Jl. Am. Soc. Marine Draftsmen, vol. 6, no. 3, Oct. 1918, pp. 41-43, 1 fig. Review of important fundamental theories governing economical operation of boilers and propelling engines; diagram showing approximate temperature for burning fuel oil.

Propelling Power

Economy in Ocean Transportation, A. W. Robinson. Jl. Eng. Inst. Can., vol. 2, no. 2, Feb. 1919, pp. 104-108. Remarks of conservation of fuel, economy in generation and use of propelling power; question of ocean transportation as viewed by a commission appointed by British Government to study relations of Dominions to Empire and to each other.

Standardization

Standardization of Ship Steel. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 101-103. Investigation conducted by representative of U. S. Shipping Board Emergency Fleet Corporation; table of structural shapes recommended for ships.

Stresses

Stresses in Ships, Sydney V. James. Jl. Western Soc. Engrs., pp. 356-376, 8 figs. Discussion of kinds of stresses, and of methods of determining principal longitudinal stresses; results of application of such methods to study of ships of well-known type; question of shearing stresses and of situation relative to transverse-stress calculations.

Terminology

Displacement Deadweight Gross and Tonnage, T. H. Fenner. Mar. Eng. Can., vol. 8, no. 12, Dec. 1918, pp. 303-304, 4 figs. Definitions of terms used in ship's measurements.

Train Ferries

Description of the New C.N.R. Car Ferry "Canora." Mar. Eng. Can., vol. 8, no. 12, Dec. 1918, pp. 301-302, 3 figs. General design and accommodations. Main propelling machinery consists of a four-cylinder triple-expansion surface-condensing engine balanced on Yarrow, Schlick & Tweedy system.

The English Channel Train Ferry. Ry. Age, vol. 66, no. 9, Feb. 28, 1919, pp. 509-510, 3 figs. Brief notice of the Richborough ferry.

Warships

New British Warships, Engineer, vol. 127, no. 3291, Jan. 24, 1919, pp. 71-72, 9 figs. General description of recent British craft, such as Repulse, Renown, Furious, Courageous, Glorious, Ramillies, Warspite, Erin, and Argincourt.

Water Ballast

Improvements in the Construction of Ships, E. F. Spanner. Shipbuilding & Shipping Rec., vol. 13, no. 2, Jan. 9, 1919, pp. 44-46, 3 figs. System of dealing with water ballast by means of a duct keel. Abstract of paper before Instn. Engrs. & Shipbuilders in Scotland.

Wooden Ship

A Successful Type of Wooden Ship, J. B. C. Lockwood. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 86-88, 4 figs. Survey of objections against wooden ships and comparison of various designs built by different companies.

YARDS

British Production

Shipbuilding and Engineering Output. Shipbuilding & Shipping Rec., vol. 13, no. 1, Jan. 2, 1919, pp. 15-16. Records of vessels launched at British yards during 1918.

Equipment

Time Saving in Steel Ship Construction, J. H. Anderson. Jl. Engrs. Club Phila., vol. 35-10, no. 167, Oct. 1918, pp. 467-471, 29 figs. Interests affected by application, status of spot-welding in reference to shipbuilding equipment and distribution systems. Third discussion under auspices U. S. Shipping Board Emergency Fleet Corporation.

Fabricating Plants

Inland Ship-Steel Fabricating Plants of the Emergency Fleet Corporation, Leyburn G. Fishbach. Eng. News-Rec., vol. 82, no. 7, Feb. 13, 1919, pp. 332-336, 6 figs. Shops at Pottstown and Leetsdale for fabricating Hog Island material, designed to produce 10,000 tons per month each.

Launching

Novel Method of Building and Launching, J. H. Rogers. Mar. Eng. Can., vol. 8, no. 12, Dec. 1918, pp. 305-307, 4 figs. Arrangement of transfer tables and launching trucks at Can. Car & Foundry Co. whose launching dock is 1400 ft. from building ways.

Planning Control

Planning Control—Applied to the Building of Duplicated Steel Vessels, D. V. Stratton. Pacific Marine Rev., vol. 6, no. 1, Jan. 1919, pp. 107-110, 1 fig. Development work along management lines of Todd Dry Dock & Construction Corporation, Tacoma, Wash.

Steel Castings

Steel Castings Used in Ship Construction, Ben Shaw and James Edgar. Can. Foundryman, vol. 10, no. 2, Feb. 1919, pp. 34-38, 26 figs. Pattern making, moulding and pouring of steel castings intended to replace forgings in construction of ships.

Terminal Sheds

The Marine Terminal Shed, H. McL. Harding. Pacific Marine Rev., vol. 16, no. 1, Jan. 1919, pp. 123-124, 1 fig. Suggestions in regard to construction and equipment.

Thornycroft Works

Messrs. Thornycrofts' Basingstoke Works. Engineering, vol. 107, no. 2768, Jan. 17, 1919, pp. 76-79, 10 figs. Illustrated description of works and equipment.

Welding

The Difficulties of Welding Steel by the Oxy-Acetylene Process, B. K. Smith. Mech. World, vol. 64, no. 1668, Dec. 20, 1918, pp. 297-298. Abstract of paper before North-Western Welding Assn.

The Application of Electric Welding to Ship Construction. Shipbuilding & Shipping Rec., vol. 13, no. 1, Jan. 2, 1919, pp. 5-6. Method adopted by British Admiralty in electric welding of watertight joints for ship structures and oil tanks subjected to heavy stresses.

Welding as a Process in Ship Construction, S. V. Goodall. Proc. Am. Inst. Elec. Engrs., vol. 38, no. 3, Mar. 1919, pp. 329-335. Review of what has been done in substituting welding for riveting in shipbuilding. Writer's opinion concerning general adoption of welding.

Organization and Management

ACCOUNTING

Graphical Analysis

Graphical Analysis of Accounting, Walter E. Gaby. Min. & Sci. Press, vol. 118, no. 8, Feb. 22, 1919, p. 260, 1 fig. Proposes scheme of representing in form of flow sheet the elements of double-entry bookkeeping.

See also ORGANIZATION AND MANAGEMENT, Finance and Cost (Cost Accounting).

EDUCATION

Crippled Workmen

Cut Metal Trade's Disability Costs, Douglas C. McMurtrie. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 445-446. Work of Red Cross Inst. for reëducation of crippled and disabled men, New York City.

Re-education vs. Disability Compensation, Douglas C. McMurtrie. Am. Mach., vol. 50, no. 9, Feb. 27, 1919, pp. 405-406. A plea for the re-education of the disabled worker rather than the pension and his neglect.

Disabled Soldiers and Sailors, Douglas C. McMurtrie. Salt Lake Min. Rev., vol. 20, no. 21, Feb. 15, 1919, pp. 29-30. Work of reëducation at Red Cross Inst. for Crippled and Disabled Men, New York City.

L'Hôtel des Invalides, at Avignon, Jules Véran. Am. Jl. Care for Cripples, vol. 7, no. 2, pp. 139-141. Discusses establishment of institution for war cripples. Translated from Revue Interallieé pour l'Etude des Questions intéressant les Mutilés de la Guerre, vol. 1, pp. 285-289.

Placement of Disabled American Soldiers and Sailors; Agreement Between Federal Board for Vocational Education and United States Employment Service. Am. Jl. of Care for Cripples, vol. 7, no. 2, 1918, pp. 154-156.

The Problem of the Discharged Disabled Man, H. H. C. Baird. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 117-125. Insufficiency of present means of readaptation; conditions resulting from public indifference. From Outlook.

A Record of Practical Experience in Retraining Crippled Ex-Service Men, A. G. Baker. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 109-111. Notes of the Superintendent, Pavilion Military Hospital, Brighton, England.

Re-Education from the Point of View of the Disabled Soldier, Grace S. Harper. Am. Jl. of Care for Cripples, vol. 7, no. 2, 1918, pp. 85-87. Translated from Revue Interalliée pour l'Etude des Questions interessant les Mutilés de la Guerre, vol. 1, 1918, pp. 254-258.

Should Disabled Men be Re-Educated in Special Schools? L. Alleman. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 100-104 Translated from French address to Inter-Allied Conference on the After-Care of Disabled Men. (Reports pp. 171-178.)

Social Responsibilities in the Rehabilitation of Disabled Soldiers and Sailors, Douglas C. McMurtrie. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 126-132. Duties of the family, of the employer, and of the general public. From Medical Rev.

So Comes the Sacred Work, John Galsworthy. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 88-91. Extent of reëducation work the nations will have to undertake.

The Training of the Disabled South African Soldier and Its Lesson, E. N. Thornton. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 105-108, 4 figs. Paper at Inter-Allied Conference on Disablement Problems Arising out of the War.

The Vocational Rehabilitation Act. Am. Jl. of Care for Cripples, vol. 7, no. 2, 1918, pp. 142-144 Text of measure as signed by President Wilson.

The Vocational School for Disabled Soldiers at Nantes, France, Emmanuel Chastand. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 92-99, 8 figs. Claims that experience has shown that reëducational school which comprises shops, classrooms, dormitories, and dining rooms is best agency for refitting for work disabled soldiers; training in private shop is considered as ineffective.

What the Employers of America Can Do for the Disabled Soldiers and Sailors. Jl. Acetylene Welding, vol. 2, no. 8, Feb. 1919, pp. 381-384 and 398. Coöperation the oxy-acetylene industry can offer. Vocational rehabilitation series no. 3 of Federal Board for Vocational Education.

Education and Democracy

Industry, Democracy and Education, C. V. Corless. Bul. Can. Min. Inst., no. 83, Mar. 1919, pp. 257-272. Address at joint session Am. Inst. Min. Engrs. and Can. Min. Inst.

Navy Machinists

How the Navy Trains its Machinists Ashore, Willard Connely. Am. Mach., vol. 50, no. 9, Feb. 27, 1919, pp. 397-400, 6 figs. Training comprises courses in machine work, pattern making, molding, blacksmithing, sheet-metal working, oxyacetylene welding, boat building and gasoline-engine construction and repair.

Research Work by Students

Reforms in the Technical Engineering Education (Ideas sobre la reforma de la ensenanza tecnica), Ramon Salas Edwards. Anales del Instituto de Ingenieros de Chile, vol. 18, no. 9, Sept. 1918, pp. 388-395. Concerning personal research work by engineering students.

Students in Coal Mining

The Training of Students in Coal Mining, Engineering Training Organization, F. W. Hardwick. Tran. Instn. Min. Engrs., vol. 56, part 2, Dec. 1918, pp. 94-100, and (discussion) pp. 119-126. Lays emphasis on practical training of students at collieries.

Training Department, Aircraft Factory

Installing a Training Department, James W. Russell. Indus. Man., vol. 57, no. 3, March, 1919, pp. 177-182, 10 figs. Descriptive of the school for training 400 women weekly for a variety of positions, including clerical, metal-working, wood-working and drafting occupations at the Buffalo factory of the Curtiss Aeroplane & Motor Corporation.

EXPORT

Foreign Plant Construction

Americans Build Foreign Plants, V. G. Iden. Iron Trade Rev., vol. 64, no. 8, Feb. 20, 1919, pp. 509-513. Discusses opportunities for American enterprises and capital.

FACTORY MANAGEMENT

Department Heads

Executive Common Sense in the Workshop, Abe Winters. Can. Machy., vol. 21, no. 7, Feb. 13, 1919, pp. 157-159. Circular letter to department heads of Standard Oil Co. Also in Can. Foundryman, vol. 10, no. 2, Feb. 1919, pp. 46-48.

Employment Management

Handbook on Employment Management in the Shipyard. Bulletin II. The Employment Building. U. S. Shipping Board Emergency Fleet Corporation, Employment Management Branch, Oct. 1918, 29 pp. 4 figs. General requirement of employment building; recommended plans for employment buildings.

Hiring Methods

Selecting Employees. Natural Gas & Gasoline Jl., vol. 13, no. 2, Feb. 1919, pp. 65-68. Method of Laclede Gas Light Co. Applicant appears separately before five examiners who test him and draw reports on appearance, mentality, native ability, mental alertness and past record, respectively.

Industrial Laws

Managing for Maximum Production, L. V. Estes. Indus. Man., vol. 57, no. 3, March 1, 1919, pp. 169-175, 5 figs. Principles and laws in industry. First of a series of articles.

Labor Saving

Plant for War and Peace. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 2-3. Concerning saving of labor.

Labor-Saving Devices

Labor-Saving Devices, George Frederick Zimmer. Eng. Rev., vol. 32, no. 7, Jan. 15, 1919, pp. 189-191. Relative advantages and possibilities of mechanical means for handling.

Management of Employees

Developing Ambition and Confidence in Employees, George Wehrle. Gas Age, vol. 43, no. 3, Feb. 1, 1919, pp. 129-131. Suggestions to general managers of gas works.

Mental Tests

Mental Tests in Industry, Robert M. Yerkes. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 405-419, 16 figs. Brief account of methods for measuring intelligence prepared for use in U. S. Army, of typical results, and of their practical applications.

Office-Building Management

Building Manager and Chief Engineer, Edward H. Kearney. Nat. Engr., vol. 23, no. 2, Feb. 1919, pp. 57-59. Incidents in daily routine of managing an office building; importance of engineering and cleaning departments.

Purchasing

Method of Purchase Expediting, Harry M. Sutton. Indus. Man., vol. 57, no. 3, March 1919, pp. 230-231, 2 figs. Chart intended to eliminate delay.

Standardization of Methods

The Control of Methods, Processes and Materials in a Manufacturing Plant, H. L. Campbell. Proc. Steel Treating Research Soc., vol. 2, no. 2, 1919, pp. 20-31, 2 figs. Way in which a research department assisted in improvement and standardization of methods, processes and material used in a manufacturing plant.

Stock Room

The Storage of Electric Supplies. Jl. Electricity, vol. 42, no. 4, Feb. 15, 1919, pp. 161-162, 3 figs. General description of office and warehouse of wholesale firm.

Toolroom Organization

Modern Tool Room Organization. Machinery, vol. 13, no. 331, Jan. 30, 1919, pp. 477-479, 7 figs. Scheme for recording and costing jigs and fixtures.

See also MECHANICAL ENGINEERING, Handling of Materials.

FINANCE AND COST

Cost Accounting

Cost Accounting to Aid Production, G. Charter Harrison. Indus. Man., vol. 57, no. 3, March 1919, pp. 218-224, 3 figs. Importance of deliberation in introducing changes.

Equipment and Maintenance Factors in Cost Accounting During Transition Period, L. W. Alwyn-Schmidt. Am. Mach., vol. 50, no. 8, Feb. 20, 1919, pp. 366-368. Book value of equipment; readjustment equipment for new work; revaluation of all equipment recommended; charges for depreciation; how can each job be apportioned?

Fundamentals of a Uniform Cost Accounting System, G. A. Schonlau. Eng. World, vol. 14, no. 4, Feb. 15, 1919, pp. 58-60. General remarks on standardization and discussion of accounting method for manufacturers of concrete pipe and tile. From Proc. Am. Concrete Pipe Assn.

Costing

Accurate Costing in Engineering. Eng. Rev., vol. 32, no. 7, Jan. 15, 1919, pp. 187-188. Selection of proper standard of value is given as first step in scheme for preparing standard cost system.

Costing and Labor

The Workers' Interest in Costing, M. Webster Jenkinson. Iron & Coal Trades Rev., vol. 98, no. 2657, Jan. 31, 1919, pp. 127-130. Attainment of efficiency and progress through taking workers in confidence of management. From paper before Conference of Indus. Reconstruction Council.

INSPECTION

See Design (Inspection) under AERONAUTICS.

LABOR

Contract and Bonus Systems

Day Labor, Force Account Work and Bonuses on Highway Construction, Charles M. Upham. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 31-33. Pronounces contract system more economical than day labor and discusses advantages of bonus system.

Contract vs. Day Labor

Performing Municipal Construction Work by Day Labor in Flint, Michigan, Ezra C. Showcraft. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 66-67. Volume of day labor; contract vs. day-labor system; opinion as to success.

Construction Projects

City and County Engineers Write of Construction Projects Planned to Provide Buffer Employment for Labor During Readjustment Period. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 37-46. Reports from 57 engineers.

Distribution of Labor

Distribution of Labor. Times Eng. Supp., year 15, 531, Jan. 1919, pp. 3-4. Discussed from viewpoints of work, skill and direction

Employee Representation

Steel Plant Industrial Relations Studied Blast Furnace, vol. 7, no. 2, Feb. 1919, pp 101-104 and 118. Plan developed and in us by a company, whereby elected employee rep resentatives meet and discuss problems o management and welfare.

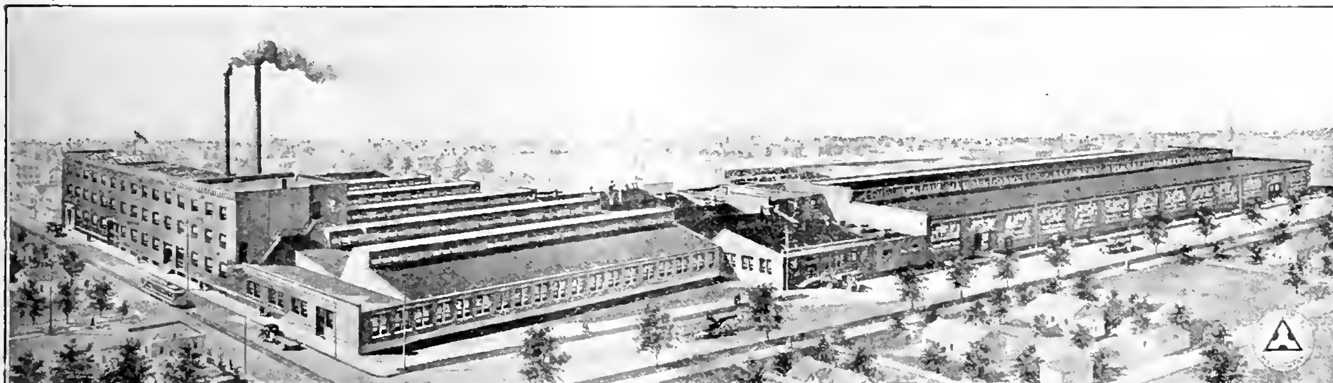
Let Us Do Your Special Work

All Firms have Work that they are not Prepared to Handle

Special and Experimental Work that must be done with speed and accuracy; but lack of room, limited time and the purchase of extra equipment make this class of work troublesome and profitless.

Quantity Production Work means additional equipment, and additional equipment means added space and extra help. Our adequate facilities for this work will reduce your costs and increase your profits.

Save time and money by letting S. A. S. Laboratories, an organization of experts and modern methods, do this work for you.



SLOCUM, AVRAM & SLOCUM LABORATORIES, INC.
NEWARK, N. J.

The Plant That is Ready to Serve You

The Slocum, Avram & Slocum plant, now in its fourth year, has earned its notable position by a successfully maintained policy of accuracy and high quality at a fair price. It has attained a foremost standing in its field, by superior workmanship, by excellence of mechanical design, and by certainty of delivery. A modern plant with up-to-the-minute equipment—every employee a specialist—backed by an unusually wide experience in special work.

It will pay you to try us on your special requirements —to learn what we can do for you—to get our prices

This is the first of a series of advertisements that will show you our plant, our methods and he work we do. Watch for them.

LET US BUILD YOUR SPECIAL MACHINES

SLOCUM, AVRAM & SLOCUM LABORATORIES, Inc.

SLOCUM-AVRAM-SLOCUM MANAGEMENT

IT WILL BE RIGHT IF WE BUILD IT

Hours of Work

The Eight Hour Day Defined. Nat. Indus. Conference Board, Research report no. 11, Nov. 1918, 9 pp. Comparison and analysis of different senses in which word is used and of principles on which demands for each type of a so-called 8-hr. day are based. Also in Eng. & Min. Jl., vol. 107, no. 6, Feb. 8, 1919, pp. 271-273.

Hours of Work as Related to Output and Health of Workers. Wool Manufacturing. Nat. Indus. Conference Board, Research Report no. 12, Dec. 1918, 69 pp. Based upon data gathered by means of schedules of inquiries addressed to members of Nat. Assn. Wool Mfrs., and to other wool manufacturers, and by field investigation.

Shorter Hours. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 5 and 7. Expected effects on output.

Housing

The Group House—Its Advantages and Possibilities, Richard Henry Dana. Am. Architect, vol. 115, no. 2249, Jan. 29, 1919, pp. 163-165. Address delivered at Annual Conference of Housings in America.

Housing Construction at Craddock. Mun. Jl., vol. 46, no. 4, Jan. 25, 1919, pp. 61-63, 4 figs. Project to provide homes for 5,000 workers. Central concrete plant serving entire project.

Industrial Fatigue

Reducing Industrial Fatigue. Automotive Industries, vol. 40, no. 4, Jan. 23, 1919, pp. 219-221. Suggestions of Divisional Committee on Industrial Fatigue of Division of Scientific Research, U. S. Public Health Service.

Industrial Relations

Improving Relations of Employer and Employee, Elec. Wld., vol. 73, no. 9, March 1, 1919, pp. 418-419. Discussion by Richard H. Rice of ways to bring about a closer and better relationship between employees and the industry.

Labor Agreements

The 47-Hour Week and 8-Hour Day. Ry. Gaz., vol. 30, no. 2, Jan. 19, 1919, p. 40. Terms of understanding arrived at between representatives of Engineering and Nat. Employers' Federations, Shipbuilding Employers' Federation, and Amalgamated Soc. Engrs. and Unions Affiliated to Eng. and Shipbuilding Trades and Federations.

Labor Conditions in 1917

Labour Conditions in 1917. S. A. Jl. Industries, vol. 1, no. 15, Nov. 1918, pp. 1426-1433. Abstract of annual report for 1917 of superintendent and chief inspector of white labor union of South Africa.

Labor Conditions in 1918

A Review of the Labor Conditions of 1918. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 63-65. Measures introduced to secure help on account of shortage of employees.

Labor Market

The Labor Market. New York State Indus. Commission Bul., vol. 4, no. 5, Feb. 1919, pp. 98-99. Employment in N. Y. State factories in Jan. 1919; wages and cost of living in Dec. 1918.

Labor Outlook

The Labor Outlook for the Coming Year, Hugh Reid. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 43-45. Past and present conditions in relation to future prospects; influence of federal supervision.

Outlook for Labor Generally Improved. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 68-70. Review of situation in various parts of the country during 1918, and discussion of 1919 prospects.

Productivity of Labor

The Principles of Employing Labor, E. H. Fish. Indus. Man., vol. 57, no. 3, March 1919, pp. 203-207. The author points out two ways of increasing the amount of labor effort in industry; bring out labor that has retired; increase the productive work of each individual employed.

Profit Sharing

How Valuable Are Profit-Sharing Plans? Harry Tipper. Automotive Industries, vol. 40, no. 4, Jan. 23, 1919, pp. 209-210. Claims that any system which attempts to satisfy the physical necessities of the worker without increasing his responsibility must fail.

Rest Periods

Rest Periods for Industrial Workers. Safety Eng., vol. 37, no. 2, Feb. 1919, pp. 77-78. Investigation by Nat. Indus. Conference Board.

Social Surroundings of Labor

Social Surroundings Have Important Bearing on All Labor Questions, Harry Tipper. Automotive Industries, vol. 40, no. 7, Feb. 13, 1919, pp. 366-367. Points out that comfort and home life of worker will modify extent and acuteness of unrest and migration.

Soldier Apprentices

Soldier Apprentices. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 9. Scheme of state assistance.

Trade Unions

Trade Unions and Production. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 4-5. Reports engineers express view that trade unions have not helped production in past and are not likely to help it in future.

Unemployment Statistics

Unemployment Figures Mere Guess. Iron Trade Rev., vol. 64, no. 9, Feb. 27, 1919, pp. 580-584, 1 fig. Claims figures of Federal Employment Service on unemployment are inaccurate.

Wages and Cost of Living

Salaries and the High Cost of Living (Les salaries et la vie chère). Revue Générale de l'Electricité, vol. 5, no. 6, Feb. 8, 1919, pp. 235-236. Proposes increase of salaries on pro rata basis of percentage of increase in price of principal commodities. From Moniteur des Intérêts matériels, Jan. 8, 1919.

Welfare Work

Welfare Work Among Maintenance Men. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 40-42, 6 figs. Pennsylvania Railroad's educational courses and camps.

Women

Employment of Women Workers in Our Industries. Gas Age, vol. 43, no. 3, Feb. 1, 1919, pp. 123-128, 7 figs. Standards for employment of women issued by U. S. Dept. of Labor; costumes in England and America; experiences of gas companies.

What Women Earn at Work. New York State Indus. Commission Bul., vol. 4, no. 5, Feb. 1919, p. 83. Data and figures compiled by Bureau of Statistics.

Women Can Handle Exacting Work, J. Edward Schipper. Automotive Industries, vol. 40, no. 5, Jan. 30, 1919, pp. 266-267, 2 figs. Experiences of some manufacturers concerning adaptability of female labor.

Women in Electrical Industry. Safety Eng., vol. 37, no. 2, Feb. 1919, pp. 67-73, 12 figs. Working conditions at Westinghouse plant where 4000 women are employed.

Organization and Management

Women in Industry, Their Work and Their Health, Samuel Semple. Safety Eng., vol. 37, no. 1, Jan. 1919, pp. 17-19. Social effects of employment of women. From Proc. Seventh Annual Safety Congress.

Working Conditions

Works Life. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 7-8. Discusses influences affecting workers personally.

Workmen's Compensation

Workmen's Compensation Legislation of the United States and Foreign Countries, 1917 and 1918. U. S. Dept. of Labor, Bur. of Labor Statistics, Workmen's Insurance and Compensation Series, no. 243, Sept. 1918, 477 pp. Enactments, new and amendatory, made by the State legislatures during 1917 and up to July 1918. Some changes in foreign legislation are also noted.

LEGAL

Compensation Acts

The "Coverage" of the Compensation Acts, Chesla C. Sherlock, Am. Mach., vol. 50, nos. 7 and 8, Feb. 13 and Feb. 20, 1919, pp. 319-321 and pp. 354-356. Second and third article. Second article establishes who are employees and when they are entitled to compensation, with an incursion into question of dependents and when they come under protection of compensation laws. Third article makes distinction between accidents occurring "out of" and "in course of" employment and at other times technically construed by citations from American and English courts.

Joint Sales Agencies

Legality of Joint Sales Agencies, A. L. H. Street. Coal Age, vol. 15, no. 9, Feb. 27, 1919, pp. 404-405. Court decisions concerning propriety of forming a pool for sale of members' products. Coal and fuel companies have been involved in cases quoted.

Tools, Laws on Use of

The Law Relating to the Use of Tools, Chesla C. Sherlock. Iron Age, vol. 103, no. 7, Feb. 13, 1919, pp. 427-428. Rule of simple tool and its application; employer's duty of inspection limited; important exceptions.

LIGHTING

Economic Aspects

Economic Aspects of Industrial Lighting, C. E. Clewell. Elec. World, vol. 73, no. 8, Feb. 22, 1919, pp. 371-374, 7 figs. Cost vs. wages; increased production and greater accuracy in workmanship; less eye strain; stimulating effect; comfort of workmen; more neatness.

Office

Modern Office Lighting, A. L. Powell. Elec. World, vol. 73, no. 7, Feb. 15, 1919, pp. 316-320, 4 figs. Lighting system for new office building of Edison Lamp Works was designed by illuminating engineers in advance of construction period; extensive tests indicate importance of careful maintenance of fixtures and walls.

PUBLIC REGULATION

Price Regulation

Gas Coke Price Escapes Regulation in Germany. Gas Age, vol. 43, no. 3, Feb. 1, 1919, pp. 140-142. Upon profiteering under wartime conditions. From Journal für Gasbeleuchtung.

Railways, Electric

The Trend of Regulation. Aera, vol. 7, no. 7, Feb. 1919, pp. 677-684. Discussions and opinions of courts and commissions concerning electric railways.

Rates

Rate Adjustment, Valuations, and Some of the Problems Incident Thereto, G. M. Garland. Mun. & County Eng., vol. 56, no. 2, Feb. 1919, pp. 74-76. Situation likely to arise in operation and management of public utilities by reason of general opinion.

Utility Valuation

Need of a Revised Principle of Utility Valuation, Robert L. Hale. Gas Age, vol. 43, no. 3, Feb. 1, 1919, pp. 137-139. Discusses decisions of Wis. R. R. Commission.

Water Power, Canada

Water-Power Administration in Canada, H. W. Grunsky. Can. Engr., vol. 36, no. 7, Feb. 13, 1919, pp. 209-211. Summary of existing laws, regulations and practices in Quebec, Ontario, Prairies Provinces and Territories, and British Columbia.

See also AERONAUTICS, *Applications (Regulation).*

RECONSTRUCTION

Automotive Industry, England

European Expansion Under War Pressure—I and II, David Beecroft. Automotive Industries, vol. 40, nos. 7 and 8, Feb. 13 and Feb. 20, 1919, pp. 345-348 and 403-406. Developments in factory enlargement, features of electric starting and lighting. Problem of reorganization of industry on peace basis.

British Views

The Return to Civil Industry. Problems of Engineering Production. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 1-2. Views of leading manufacturers.

Canadian Organization

Canada Organizing for Vast Trade. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, p. 453. List of commodities for which there is an immediate market in Belgium, prepared by Can. Mfrs.' Assn.

Cooperation

Coöperation Vital in Reconstruction. Iron Trade Rev., vol. 64, no. 6, Feb. 6, 1919, pp. 381-382. British business leaders declared, at London meeting held jointly with American business paper editors, that new tasks cannot be accomplished unless capital and labor continue teamwork as during war.

Peace Problems Demand Coöperation, G. W. Thompson. Chem. Engr., vol. 27, no. 2, Feb. 1919, pp. 43-44 and 48. Suggests that chemical industries, by means of Webb law, open price associations and through greater coöperation prepare themselves to meet foreign competition and internal conditions.

Engineering Forecast

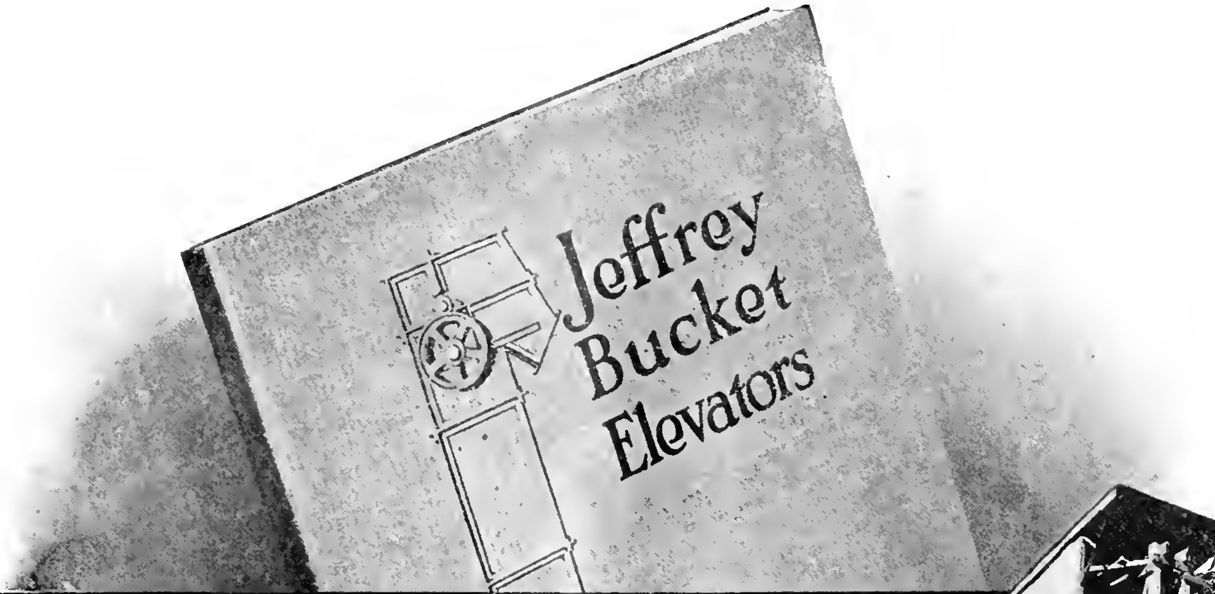
Engineering and Industrial Forecast, W. T. Christine. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 55-57. Writer's opinion concerning opportunities for profitable business.

France

Economic Organization of the Country After the War (L'organisation économique du pays après la guerre). Echo des Mines et de la Metallurgie, vol. 47, no. 2613, Feb. 16, 1919, pp. 108-110. Report of commission appointed by French senate.

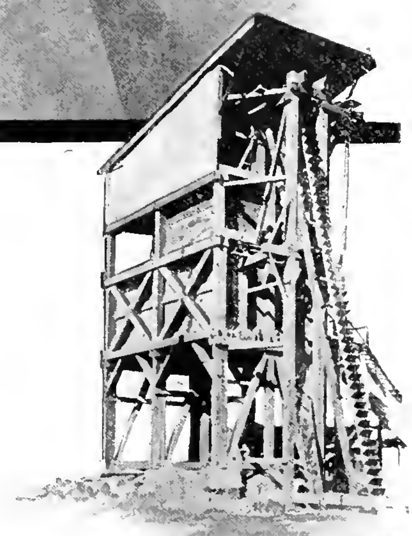
Engineering conditions in France. Mech. Eng., vol. 41, no. 3, Mar. 1919, pp. 262-264. Expressions from American engineer-delegates to conference with French engineers on reconstruction problems.

The Rebuilding of Devastated France, John V. Schaefer. Eng. World, vol. 14, no. 2,



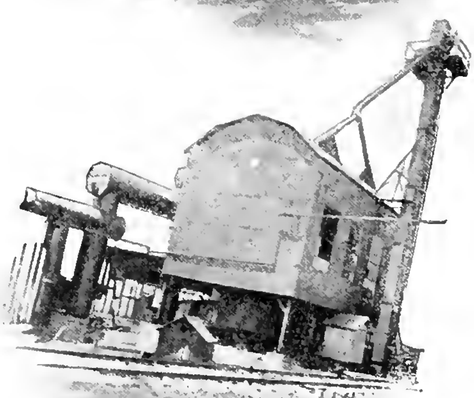
A Valuable Book for

Engineers — Contractors Manufacturers



The outstanding feature of the new Jeffrey Catalog is the ease with which a Jeffrey Standard Elevator can be selected from the 40 pages of complete layouts, and specifications to exactly meet your requirements.

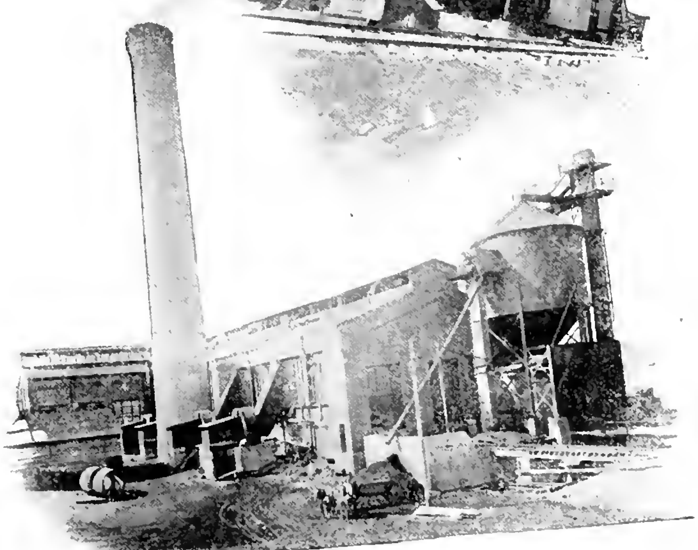
In addition to saving the expense of layouts and drawings, the purchaser is benefited by a quicker delivery made possible by the placing of Jeffrey Standard Elevators upon a manufacturing basis.



Some of the Examples and Subjects Outlined in this Book

Capacity of Jeffrey Standard Elevators
How to select a Jeffrey Standard Elevator
Jeffrey Standard Steel Casings
General arrangement of Standard Trackhoppers with line drawings giving dimensions
Suggestions for installation of Jeffrey Standard Elevators with line drawings

Write TODAY for copy of Catalog No. 244-F.



The Jeffrey Mfg. Co.

904 North Fourth Street
Columbus, Ohio

Handle it Mechanically

Jan. 15, 1919, pp. 56-58. Exposition of suggestions that have been offered in regard to the coöperation of U. S. Government with French Government.

Government Sales Plan

Government's Sales Plan Outlined. Iron Trade Rev., vol. 64, no. 6, Feb. 6, 1919, p. 389. Disposal of surplus war products to be effected through coöperation between War Dept.'s sales division and U. S. Chamber of Commerce.

Philadelphia

Reconstruction in Philadelphia After the War, Albert N. Hogg. Jl. Engrs.' Club Phila., vol. 35-12, no. 169, Dec. 1918, pp. 553,554. Declares need for a better knowledge of business methods on the part of engineers.

Public Utilities

Maintenance of Public Utility Plants, Robert J. Thomas. Mun. & County Eng., vol. 56, no. 1, Jan. 1919, pp. 14-15. Effect of war conditions.

Selling Prices

Business Dividend on Redfield Plan. Iron Trade Rev., vol. 64, no. 8, Feb. 20, 1919, pp. 495-496. Opinions concerning practicability of plans suggesting prices for basic commodities.

Proper Joint Plan to Lower Prices. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 456-457. Secretary Redfield's plan to determine fair selling prices in basic industries without lowering wages.

SAFETY ENGINEERING

Cooperation in Accident Prevention

Pull Together to Decrease Accidents, E. B. Van Doren. Elec. World, vol. 73, no. 8, Feb. 22, 1919, pp. 368-369, 3 figs. Coöperation between employer and employee to increase production and efficiency and reduce accidents; safety welfare committees should encourage suggestions.

Education of Workers

Foundry Management from Standpoint of Accident Prevention, G. A. Hart. Safety Eng., vol. 37, no. 1, Jan. 1919, pp. 12-13. Remarks on education of workers concerning safety methods and precautions. From Proc. Seventh Annual Safety Congress.

Employment

Scientific Employment and Its Relation to Accident Prevention, R. W. Immel. Safety Eng., vol. 37, no. 2, Feb. 1919, pp. 75-76. Suggests character analysis and allocation of individuals to work which they can adequately and safely perform.

Fire-Alarm Systems

Central Fire Alarm Station of San Francisco. Elec. Rev., vol. 74, no. 8, Feb. 22, 1919, pp. 291-294, 7 figs. Unusually complete equipment; special provision to insure reliability of power supply and interchangeability of circuits; method of operating.

Fire Prevention and Fighting

Extinguishing and Preventing Oil and Gas Fires, C. P. Bowie. Dept. of Interior, Bur. of Mine, bul. 170, Petroleum Technology 48, 50 pp., 4 figs. Points out what has been done by operators in the past, and describes various fire-prevention methods and fire-fighting apparatus.

Safety Organization

Safety, Sanitation and Welfare. Safety Eng., vol. 37, no. 2, Feb. 1919, pp. 53-58, 2 figs. Safety organization of U. S. Steel Corporation.

Shipyard Sanitation

Sanitation in Emergency Shipyards, W. L. Stevenson, vol. 6, no. 1, Jan. 1919, pp. 1-18, 8 figs. Work of Department of Health and Sanitation of U. S. Shipping Board.

See also MINING ENGINEERING, Mines and Mining (Health Control), (Safety Devices); MECHANICAL ENGINEERING, Power Plants (Safety); RAILROAD ENGINEERING, Shops (Safety Devices).

SALVAGE

Creamery Wastes

Treatment and Disposal of Creamery Wastes, Earle B. Phelps. Mun. Jl., vol. 46, no. 4, Jan. 25, 1919, pp. 68-70, 1 figs. Settling tank and sand bed designed and tested by U. S. Public Health Service. From Public Health Reports.

Metal-Waste Reclamation

Reclamation of Waste to Be Extended. Iron Trade Rev., vol. 44, no. 3, Jan. 16, 1919, pp. 220-221. Estimates on reclamation of metals by new division of Dept. of Commerce on waste reclamation service.

Salvage Organization

Scientific Salvage, H. N. Sessions. Jl. Electricity, vol. 42, no. 3, Feb. 1, 1919, pp. 105-107, 2 figs. How the Southern Cal. Edison Co. directs its salvage work.

Scrap Business

Huge Loss of Steel Brings Problem, G. H. Manlove. Iron Trade Rev., vol. 64, no. 6, Feb. 6, 1919, pp. 371-375, 6 figs. Claims that obliteration of millions of tons of American material on foreign battlefields disrupts normal cycle of scrap recovery.

Waste Prevention

Conservation of Material by the Store Department, J. G. Stuart. Ry. Age, vol. 66, no. 9, Feb. 1919, pp. 497-500. Care in ordering and handling to prevent waste; systematic methods needed in reclamation. From a paper before the Railway Storekeepers' Association, January, 1919.

Waste Utilization

Instructive Examples of Utilizing Industrial Wastes, H. E. Howe. Indus. Man., vol. 57, no. 3, March, 1919, pp. 225-229. To illustrate the importance of reclaiming and utilizing wastes in industries article quotes a number of examples.

Salvaging Miscellaneous Wastes, W. R. Conover. Gen. Elec. Rev., vol. 22, no. 2, Feb. 1919, pp. 127-133. Deals with such wastes as cables, slings, belting, paper, lumber by-products, oils, power, heat and light.

TRANSPORTATION

Coal Transportation, India

The Carriage of Coal by Rail in India, H. Kelway-Bamber. Jl. Royal Soc. of Arts, vol. 67, no. 3454, Jan. 1919, pp. 150-161 and (discussion) pp. 161-164, 6 figs. Review of past development in the Indian coal output; forecast of future coal consumption; suggestions for reducing cost of coal transportation.

Transatlantic Rates

West Blocked on Orient Shipments. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, p. 455. Claims that transatlantic rail rates leave advantage with Atlantic ports by canal route.

See also MINING ENGINEERING, Mines and Mining (Transportation).

VARIA

Economic Duties of Engineers

The Economic Duties of the Engineer, W. R. Ingalls. Eng. & Contracting, vol. 51, no. 8, Feb. 19, 1919, pp. 193-194. From presidential address before Mining and Metallurgical Soc. of America, Jan. 1919.

Filing Systems

Uniform Filing System, C. C. Hogan. Jl. Electricity, vol. 42, no. 4, Feb. 15, 1919, pp. 170-172. Based on Dewey decimal system.

Hand for Cripples

A Compressed Air Actuated Hand for Crippled Soldiers (Die Pressluft-Hand fuer Kriegsbeschaedigte Industrie Arbeiter), W. Dahlheim. Zeitschrift fuer Komprimierte und Fluessige Gase, vol. 19, no. 2, 1917, pp. 18-19, 1 fig. Togglejoint actuated by compressed air piston, to replace the natural hand, enabling the workman to perform practically all machine shop operations, including filing. Light, simple, inexpensive.

Land Settlement

The Present Status of Land Settlement Activities for Ex-Service Men in Great Britain. Hilda A. Fox. Am. Jl. of Care for Cripples, vol. 7, no. 2, 1918, pp. 133-138. List and activities of a number of organizations, voluntary and otherwise, working for this object.

Occupational Therapy

Occupational Therapy in Military Hospitals, James E. Russell. Am. Jl. of Care for Cripples, vol. 7, no. 7, 1918, pp. 112-116. Situation at War Department. Address before Nat. Soc. for Promotion of Occupational Therapy.

Telephone Credit-Check System

Telephone System of Credit Checks, Clotilde Grunski. Jl. Electricity, vol. 42, no. 4, Feb. 15, 1919, pp. 152-153, 2 figs. Department-store credit system; uses a central telephone exchange and various stations in different parts of store.

Industrial Technology

Alcohol

Future and Sources of Industrial Alcohol. Can. Foundryman, vol. 10, no. 2, Feb. 1919, pp. 41-42. Manufacture from grain and potatoes; synthetic processes; utilization of wood waste; comparative yields.

Ammonia

Ammonia Plant at the Stockholm Gas Works. Gas Age, vol. 43, no. 3, Feb. 1, 1919, pp. 132-134, 5 figs. Plant was designed to furnish both ammonium sulphate and aqueous ammonia. From Journal für Gasbeleuchtung.

Cements for Chemical Work

Cements for Various Purposes, J. B. Barnitt. Mech. World, vol. 65, no. 1672, Jan. 17, 1919, p. 29. Joints and similar uses in chemical work. From Gen. Chem. Bul.

Charcoal

Manufacture of Charcoal as an Economic Measure, Helge Sylven. Sci. Am. Supp., vol. 87, no. 2251, Feb. 22, 1919, pp. 124-126, 5 figs. By-product made from lumber-mill waste.

Chlorine

Future Possibilities of Electrolytic Chlorine, A. H. Hoker. Chem. Engr., vol. 27, no. 1, Jan. 1919, pp. 3-4. Evolution of Mond and Deacon processes; chlorine in refining.

Coloration, Metal

Chemical Metal Coloration, Emil Haas. Brass World, vol. 15, no. 2, Feb. 1919, pp. 45-46. Describes various processes.

Cyanogen Products

The Manufacture of Hydrocyanic Acid, H. A. Pelton and M. W. Schwarz. Chem. & Metallurgical Eng., vol. 20, no. 4, Feb. 15, 1919, pp. 165-166, 2 figs. Description of semi-industrial apparatus and plans for large scale operations.

Use of Cyanogen and Its Derivatives During the War (L'emploi du cyanogene et de ses dérivés à la guerre), Nicolas Flamel. Génie Civil, vol. 74, no. 5, Feb. 1, 1919, pp. 89-92. Preparation of these chemicals; their toxic effects.

Dust Precipitation

Checking Up on Cottrell Process, N. H. Gellert. Iron Trade Rev., vol. 64, no. 7, Feb. 13, 1919, pp. 448-450, 2 figs. Results obtained in electrical precipitation of impurities from blast-furnace gases; method said to be adaptable to spiegeleisen and ferromanganese furnaces.

Electrodeposition

Electrolytic Deposition of Zinc, H. E. Broughton. Chem. & Metallurgical Eng., vol. 20, no. 4, Feb. 15, 1919, pp. 155-162, 13 figs. Preparation of cell liquor from fumes collected as sludge in acid chambers; details of theoretical and applied electrochemistry involved; charts and data.

Muriatic Acid in Nickel Solutions, E. W. Heil. Brass World, vol. 15, no. 2, Feb. 1919, pp. 39-40. Discusses advisability of adding muriatic acid to a nickel solution and the chemical phenomena resulting therefrom.

Filtration

Utilization of Waste Paper in Filtration, S. L. Jodidi and H. G. Higgins. Chem. Engr., vol. 27, no. 2, Feb. 1919, pp. 45-48, 1 fig. Method of preparing waste and low-grade paper pulp for making filters like those used in quantitative analysis; results obtained.

Galvanizing

Modern Processes of Galvanizing Sheet Steel (Procédés modernes de galvanisation des tôles d'acier). Métallurgie, vol. 51, no. 7, Feb. 12, 1919, pp. 334-335, 1 fig. English type of galvanizing machine. (Continuation of serial.)

Gas Manufacture

Steaming Vertical Retorts, L. J. Willien. Gas Rec., vol. 15, no. 4, Feb. 26, 1919, pp. 115-116. Report of tests showing increased gas and ammonia yield, and less formation of carbon in retorts. Paper before N. E. Gas Assn.

Gas Engineering. Times Eng. Supp., year 15, no. 531, Jan. 1919, pp. 22-23. Progress of gas industry in 1918.

Install Improved Apparatus, J. Arnold Norcross. Gas Rec., vol. 15, no. 4, Feb. 26, 1919, pp. 125-128. Recommendation to reduce cost of producing gas by adopting improvements likely to reduce expenses and save labor. Presidential address before N. E. Gas Assn.

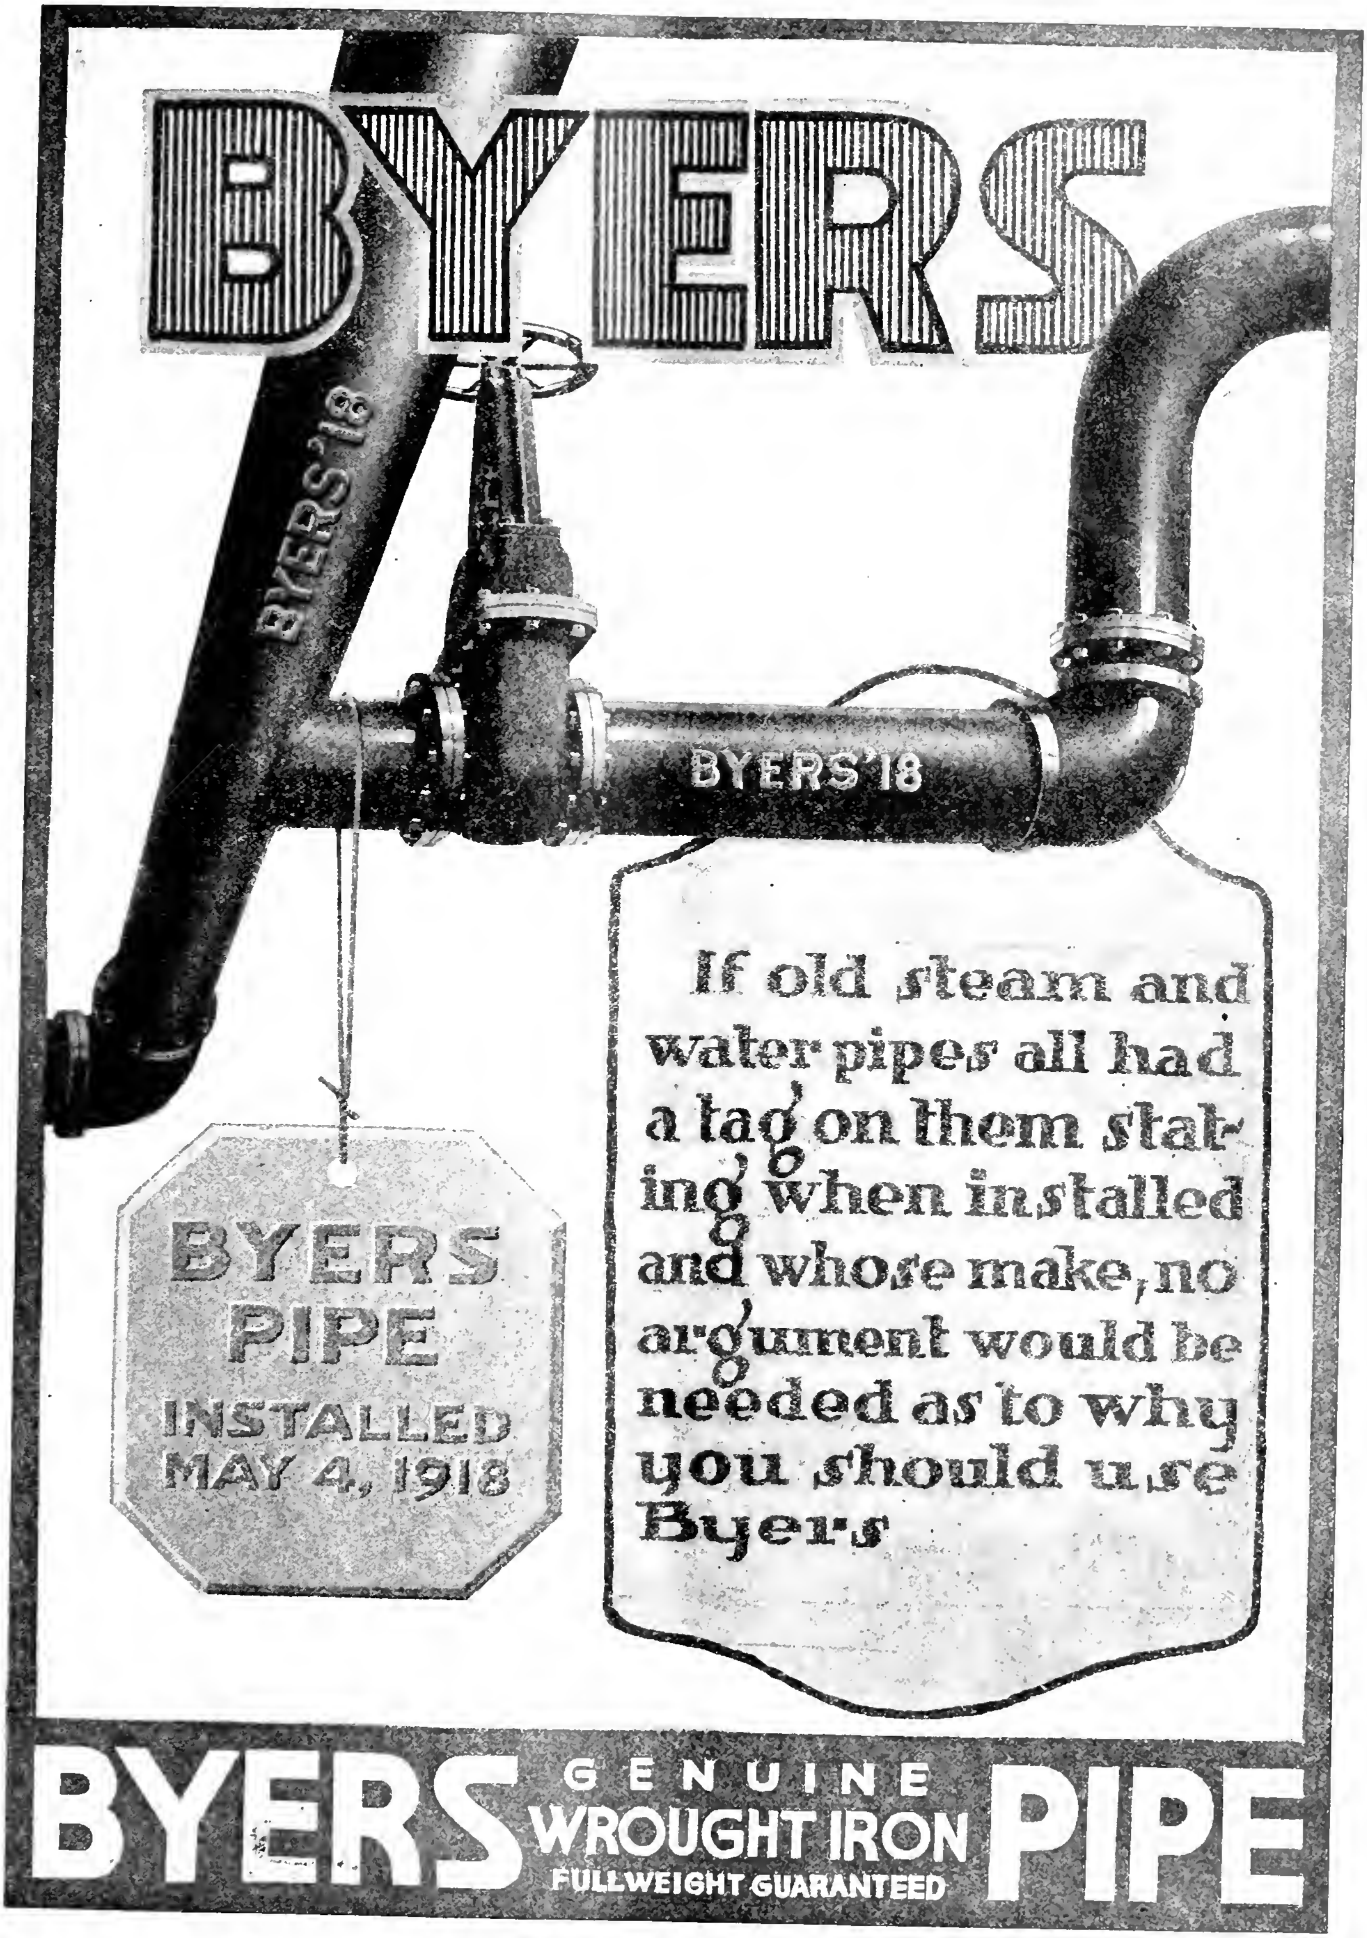
Gasoline

Gasoline from Natural Gas, G. A. Burrell. Gas Rec., vol. 15, no. 4, Feb. 26, 1919, pp. 105-108. Discussion of various types of plants available and some of essential points in their operation.

Gasoline Recovery, E. A. Spencer. Natural Gas & Gasoline Jl., vol. 13, no. 2, Feb. 1919, pp. 51-52, 1 fig. Absorption process described and illustrated.

Glass

Laboratory Glassware in England (La verrerie de laboratoire en Angleterre), A. Livache. Bulletin de la Société d'Encouragement, vol. 130, no. 6, Nov.-Dec. 1918, pp. 411-424. Experimental research of the action of chemical reagents on glass surfaces; comparison



BYERS
BYERS '18
BYERS '18
BYERS PIPE
INSTALLED MAY 4, 1918
If old steam and water pipes all had a tag on them stating when installed and whose make, no argument would be needed as to why you should use Byers
BYERS GENUINE WROUGHT IRON PIPE
FULLWEIGHT GUARANTEED

of the various types of laboratory glassware. From Jl. Soc. Glass Technology, vol. 1, 1917, p. 153.

The Condition of Arsenic in Glass and Its Role in Glass-Making. E. T. Allen and E. G. Zies. Jl. Am. Ceramic Soc., vol. 1, no. 11, Nov. 1918, pp. 787-790. Writers claim that in all glasses they have tested, both plate and optical glasses, major part of arsenic present exists in pentavalent state and a portion in trivalent state.

Some Aspects of the Scientific Glassware Industry, F. W. Branson. Jl. Soc. Chem. Indus., vol. 37, no. 24, Dec. 31, 1918, pp. 337T-339T and (discussion) pp. 339T-340T. Suggests standardization of hollow scientific glassware.

Graphite Crucibles

Preparation of Crucible Graphite, George D. Dub. Dept. of Interior, Bur. of Mines, War Minerals Investigation Series, no. c., Dec. 1918, 27 pp., 10 figs. Survey of present mining, milling, refining, sampling, and analyzing methods; experimental work on concentration and refining undertaken for the purpose of improving present practice; investigations of crucible manufacture to determine properties of domestic flake and maximum proportions that might be used without impairing quality of crucibles.

Hydrogen

The British Admiralty Hydrogen Gas Plant. Engineering, vol. 107, no. 2769, Jan. 24, 1919, pp. 102-103, 7 figs. Description of the process and the plant constructed by the Société L'Oxylithe, Paris.

Hydrogenation of Oils

Hydrogenation of Oils (L'hydrogénation des huiles), A. Mailhe. Journal des Usines à Gaz, vol. 43, no. 3, Feb. 5, 1919, pp. 33-36. Survey of patents; choice of nickel, cobalt, iron and copper as catalyzer. (Concluded.)

Nitrogen

The Production of Nitrogen Compounds, Jack P. Montgomery. Chem. Engr., vol. 27, no. 2, Feb. 1919, pp. 35-39. Review of sources of nitrogen compounds and processes of utilizing them with special reference to methods employed to meet waste of nitrogenous material.

Pickling

Removing Oxide Scale by Pickling, E. E. Corbett. Iron Trade Rev., vol. 64, no. 9, Feb. 27, 1919, pp. 564-568. Comparison of steel-cleaning liquors made of nitre cake and sulphuric acid; mode of working solutions and chemical and mechanical reactions which take place in pickling process.

Radium

The Radium Industry and Reconstruction. John S. MacArthur. Min. Jl., vol. 124, no. 4352, Jan. 18, 1919, pp. 39-40. Points out some possible uses of low-grade radium residues.

Rubber

The Ageing of Vulcanized Plantation Rubber II, Henry P. Stevens. Jl. Soc. Chem. Ind., vol. 37, no. 24, Dec. 31, 1918, pp. 340T-342T, 8 figs. Experiments are said to have proved that vulcanized rubber commences to change in physical properties from the moment vulcanization process is completed.

Silicon Products

Metallic Silicides (Les silicinres métalliques), Jean Escard. Métaux, Alliages et Machines, vol. 12, no. 1, Jan. 1919, pp. 8-10. Preparation in electric furnace of silicon alloys; their industrial utilization. (To be continued.)

Water Gas

Control of Water Gas Sets, H. Vittinghoff. Gas Rec., vol. 15, no. 4, Feb. 26, 1919, pp. 109-112, 1 fig. Essentials in operation of small plants. Paper before N. E. Gas Assn.

Providence Water Gas Plant, W. M. Russell. Gas Rec., vol. 15, no. 4, Feb. 26, 1919, pp. 119-123. Construction and operation of sets recently installed. Paper before N. E. Gas Assn.

Railroad Engineering

ELECTRIC RAILWAYS

Center-Rail Traction

Center-Rail Traction for Mountain Railways, C. Noble Fell. Ry. Engr., vol. 40, no. 468, Jan. 1919, pp. 12-14, 5 figs. Electric center-rail permanent way (Fell system.)

Freight Handling

Freight Transportation by Local Electric Railways (Le transport des merchandises sur les voies ferrées électriques d'interêt local), Lucien Pahin. Revue Générale de l'Electricité, vol. 5, no. 3, Jan. 18, 1919, pp. 114-117. Survey of developments in United States, England and France by congestion of railroads.

Locomotive

An Electric Rail Locomotive. Motor Traction, vol. 28, no. 723, Jan. 8, 1919, p. 26, 1 fig. Equipped with battery of 120 cells of Edison G11 type; ampere-hour capacity, 275.

ELECTRIFICATION

French Railways

Consequences of the Electrification of French Railways from the Viewpoint of the Exploitation of the Telegraph and Telephone Lines (L'électrification des chemins de fer français; ses conséquences au point de vue de l'exploitation des lignes télégraphiques et téléphoniques), A. Mauduit. Annales des Postes, Télégraphes et Téléphones, vol. 7, no. 4, Dec. 1918, pp. 499-525. Investigations of the Compagnie du Midi lead writer to establish that in electrified lines with small traffic and where current does not exceed 100 amp., usual protective devices will permit successful operation of telegraph and telephone lines running parallel to track; not so, however, when rail current exceeds 100 amp.-km., in which case soil return is not judged advisable in telephone or telegraph line.

Partial Electrification of a Great Railway System (Electrification partielle d'un grand réseau de chemins de fer), Victor Sabouret. Bulletin de la Société d'Encouragement pour l'Industrie Nationale, vol. 130, no. 6, Nov.-Dec. 1918, pp. 344-363. Project of Compagnie d'Orleans comprising electrification of 3000 km. of railway.

New Zealand

The Electrification of Railways in New Zealand, E. Parry. New Zealand Jl. Sci. & Technology, vol. 1, no. 6, Nov. 1918, pp. 323-328. Relative merits of steam and electric haulage; importance of a comprehensive system of electric-power supply in its bearing upon railway electrification; evolutional process of main-line electrification in New Zealand.

EUROPEAN

Ambulance Trains

British Railways Under War Conditions. Engineer, vol. 127, no. 3291, Jan. 24, 1919, pp. 73-75, 11 figs. Ambulance trains. Fifteenth article.

British

Railways. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 30. Services given to Government by British railways during war; progress in standardization: rolling-stock construction.

LABOR

Camps

Some Modern Camps for Maintenance Men. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 49-53, 13 figs. Buildings provided by four of the roads in Chicago district.

LOCOMOTIVES

Australian Locomotives

Locomotive Built by Australian Government, J. O'Toole. Boiler Maker, vol. 19, no. 2, Feb. 1919, pp. 40-41, 2 figs. Type 2-8-0. Total heating surface, 2421 sq. ft.; Walschaerts valve gear and Robinson superheater used.

Coal Consumption

The Economical Use of Coal in Locomotives. Ry. Gaz., vol. 30, no. 2, Jan. 10, 1919, pp. 63-64, 2 figs. Abstract of report issued by engineering staff, Univ. of Ill.

Firebox, Thermic-Syphon

New Type of Locomotive Firebox. Ry. Mech. Eng., vol. 93, no. 2, Feb. 1919, pp. 71-73, 2 figs. By introduction of thermic syphons evaporating efficiency of boiler is materially increased.

Pennsylvania 2-10-2

Pennsylvania Lines 2-10-2 Locomotive. Ry. Mech. Eng., vol. 93, no. 2, Feb. 1919, pp. 74-76, 5 figs. General description, drawings and principal data.

Powdered-Fuel Engines

Locomotives. Times Eng. Supp., year 15, no. 531, Jan. 1919, p. 30. Designs developed in 1918, particularly the powdered-fuel engine.

Standard

Standard 2-6-6-2 Type Locomotive. Ry. Mech. Eng., vol. 93, no. 2, Feb. 1919, pp. 74-77, 6 figs. General description, drawings and principal data.

The Standard Heavy Santa Fe Type Locomotive. Ry. Age., vol. 66, no. 7, Feb. 14, 1919, pp. 389-392, 6 figs. General description, principal data and drawings.

Stokers

The Elvin Mechanical Stoker. Ry. Mech. Eng., vol. 93, no. 2, Feb. 1919, pp. 103-106, 4 figs. Description of stoker for locomotives made by Elvin Mechanical Stoker Co., New York.

Superheaters

Modern Locomotive Engine Design and Construction—XLIV. Ry. Engr., vol. 40, no. 468, Jan. 1919, pp. 3-12, 24 figs. Considerations relative to design and construction of different types of superheaters for any working temperature. (Continuation of serial.)

Three-Cylinder Engine

Great Northern Railway Locomotive Performance. Ry. Gaz., vol. 30, no. 3, Jan. 17, 1919, pp. 89-98, 18 figs. Haulage of 1300-ton coal trains between Peterborough and London by a three-cylinder engine.

See also MECHANICAL ENGINEERING, Power Plants (Firebox).

OPERATION AND MANAGEMENT

Fuel Conservation

Recent Papers on Fuel Conservation. Ry. Mech. Eng., vol. 93, no. 2, Feb. 1919, pp. 66-69. Abstracts of several railway club papers prepared by fuel experts and describing methods of saving coal.

Government Ownership

State Ownership and Operation of Railways. Ry. Gaz., vol. 30, nos. 1, 2 and 3, Jan. 3, 10 and 17, 1919, pp. 11-14, 48-51 and 86-88. Digest of evidence given before commission of inquiry in South Africa concerning advantages and disadvantages of state control of railways.

The National Railroad Question of To-Day, Francis Lee Stuart. Proc. Am. Soc. Civil Engrs., Papers & Discussions, vol. 45, no. 2, Feb. 1919, pp. 53-60. Facts which led up to Federal control; competition and Government ownership.

To-Day's Railroad Problem in the States, Theodore P. Shonts. Ry. Gaz., vol. 30, no. 2, Jan. 10, 1919, pp. 57-58. Claims that most economical operation can be attained under private ownership.

Loading, Maximum

Maximum Car Loading, William H. McClymonds. Proc. Pacific Ry Club, vol. 2, no. 10, Jan. 1919, pp. 16-22. Economics of loading a car to its utmost safe carrying capacity.

Speeds, European

European Train Speeds. Ry. Gaz., vol. 30, no. 3, Jan. 17, 1919, pp. 80-85. Survey of highest, longest and fastest non-stop runs, speed of trains between two places and geographical distribution of principal service. (To be continued.)

Stores, Handling

Handling of Stores on the Santa Fé, Charles E. Parks. Ry. Gaz., vol. 30, no. 2, Jan. 10, 1919, pp. 59-61. Organization to look after waste material.

Train Dispatching

Getting Trains Over the Road, J. A. Shockey. Proc. Pacific Ry. Club, vol. 2, no. 10, Jan. 1919, pp. 10-16. Duties and responsibility of a train dispatcher.

Organization of a Train Dispatcher's Office and Duties of the Chief Dispatcher, C. E. Norton. Proc. Pacific Ry. Club, vol. 2, no. 10, Jan. 1919, pp. 6-10.

See also MECHANICAL ENGINEERING, Handling of Materials (Cooling Stations).

PERMANENT WAY AND BUILDINGS

Ballast

Maintenance of Railway Roadbed by Cleaning the Ballast (L'entretien des voies ferrées par le soufflage du ballast). Génie Civil, vol. 74, no. 5, Feb. 1, 1919, p. 94, 1 fig. Methods based on maintaining solidity of supporting parts of ballast by removing vegetation, etc., by air jet, to insure percolation of water into roadbed and trenches.

Track Support, Concrete

Concrete Railway Track-Support. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 58-60, 2 figs. Details of proposed continuous concrete slab support.

ROLLING STOCK

Automobile Cars

Forty-Foot Automobile Cars for Illinois Central. Ry. Age, vol. 66, no. 8, Feb. 21, 1919, pp. 440-443, 4 figs. Single-sheathed type with steel end, especially designed for carrying various types of lading; general description and principal data.

Axles

Notes on Railway High Capacity Wagon Wheel Axles, H. Kelway-Bamber. Jl. & Tran. Soc. Engrs., vol. 9, no. 12, Dec. 1918, pp. 189-204 and (discussion) pp. 204-214, 9 figs. British 10-ton wagon axle; methods of ascertaining stresses; method of calculating dimensions, etc.; specifications for axle steel; factors of safety.

Lumber for Car Construction

Lumber for Car Construction, Hermann von Schrenk. Ry. Mech. Eng., vol. 93, no. 2, 1919, pp. 85-88, 3 figs. Selecting proper grades to secure strength and lasting power, increasing service by preservatives.

Standard Cars, U. S.

Standard Cars for the United States Railways. Ry. Gaz., vol. 30, no. 3, Jan. 17, 1919, pp. 101-102, 6 figs. Standard design for 70-ton hopper wagon.

Standards for Freight Equipment

Standards for the Maintenance of Freight Equipment, H. L. Shipman. Ry. Age, vol. 66, no. 9, Feb. 28, 1919, pp. 495-497. Keeping up the condition of cars to meet demands of traffic; uniform classification of repairs. From a paper before the Western Railway Club.

SAFETY AND SIGNALING SYSTEMS

Alternating-Current Signaling

Alternating Current Signaling. Ry. Engr., vol. 40, no. 468, Jan. 1919, pp. 15-17, 7 figs. How system was developed, how it operates, and results that have been obtained. (To be continued.)

Automatic Signaling

Automatic Signals Expedite Freight Movement. Ry. Signal Engr., vol. 12, no. 1, Jan. 1919, pp. 4-7. Study of conditions of Northern Pacific; table showing information.

Many New Conditions Affected Signaling Last Year. Ry. Signal Engr., vol. 12, no. 1, Jan. 1919, pp. 11-23. Review of progress made in automatic block and interlocking construction developments and personnel of signal field.

Signal Lamps, Focusing

A Method of Focusing Signal Lamps, S. C. Hofmann. Ry. Signal Engr., vol. 12, no. 1, Jan. 1919, pp. 30, 1 fig. Details of focus tube for focusing R. S. A. semaphore lamps, claimed to have given satisfactory service.

Ties, Zinc-Treated, and Current Leakage

Influence of Zinc Treated Ties on Signal Operation. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 65-66. Experiences of various engineers. Discussion at convention Ry. Signal Assn.

SHOPS

Boiler Shops

Among Railroad Boiler Shops—VI, James F. Hobart. Boiler Maker, vol. 19, no. 2, Feb. 1919, pp. 49-50 & 60, 5 figs. Devices developed for special work; front-end staging, handling locomotive tenders and special tools.

Canal Zone Shops

Our Canal Zone Dry Docks and Repair Shops, R. D. Gatewood. Am. Mach., vol. 50, no. 8, Feb. 20, 1919, pp. 336-339. General description of Balboa facilities.

Roundhouse, Concrete

An Unusual Concrete Roundhouse at Proctor, Minn., Wm. E. Hawley. Ry. Age, vol. 66, no. 8, Feb. 21, 1919, pp. 428-430, 5 figs. Saw-tooth roof applied to circular building; cantilever beams support walls over entrance doors.

Safety Devices

Safeguards in Railway Shops, Frank A. Stanley. Ry. Mech. Eng., vol. 93, no. 2, Feb. 1919, pp. 93-96, 9 figs. Description of certain safety devices used at various shops of Southern Pacific.

Welding

The Oxy-Acetylene Process in Railroad Shops, W. L. Bean. N. E. R. R. Club, Jan. 14, 1919, pp. 247-261. Development; notes on apparatus selection; accessories; instruction of welders.

TERMINALS

Richborough

The Richborough Transportation Depot and Train Ferry Terminus. Engineer, vol. 127, no. 3291, Jan. 24, 1919, pp. 76-79, 15 figs. The new wharf. Third article.

Richmond, Va.

A New Passenger Station Completed at Richmond, Va. Ry. Age, vol. 66, no. 7, Feb. 14, 1919, pp. 401-406, 9 figs. Project involves terminal with facilities for two roads and improved main line. Also in Ry. Rev., vol. 64, no. 7, Feb. 15, 1919, pp. 239-242, 9 figs. Description of three-million-dollar structure.

Terminal Sheds

Marine Terminal Shed, H. McL. Harding. Eng. World, vol. 14, no. 2, Jan. 15, 1919, pp. 47-48, 1 fig. Comparison of one-story and two-story sheds in regard to cost and speed of operation.

Yards, London

Willesden Gravity and Marshalling Yards. Ry. Gaz., vol. 30, no. 1, Jan. 3, 1919, pp. 17-24, 11 figs. and chart. Freight and coal traffic in London district of London & Western Ry.

Munitions and Military Engineering

Army Bases

Brooklyn Army Base Is Largest Port Terminal. Eng. News-Rec., vol. 82, no. 7, Feb. 13, 1919, pp. 317-323, 15 figs. Description of freight-handling unit designed for overseas service. It has 138 acres of pier and warehouse floor and track space for 1,300 cars.

Camps

The Operation of the Utilities at Camp Devens, Mass., Edward W. Briggs. Jl. Boston Soc. Civ. Engrs., vol. 6, no. 2, Feb. 1919, pp. 25-60, 4 figs. Organization and operation of various departments. Entire reservation contains 10,000 acres, of which 2,000 are occupied by camp proper.

Construction Work, U. S.

Government War Construction Work in the United States, R. C. Marshall. Proc. Am. Soc. Civil Engrs., vol. 45, no. 2, Feb. 1919, pp. 164-171. Outline of work done by Construction Division of the Army.

Coast Defense

Notes on the Use of the Aeroplane in Coast Defense, John Hays Hammond. Jl. U. S. Artillery, vol. 49, no. 4, Sept.-Dec. 1918, pp. 286-291. Functions of different types of aircraft in coast defense; problems of winter flying; twin-motored aeroplanes in coast-defense work.

Depth-Bomb Throwers

Thornycroft Depth Charge Throwers. Engineer, vol. 127, no. 3291, Jan. 24, 1919, pp. 86-88, 5 figs. Description.

Fire Control

Radio Apparatus for Artillery Fire Control, G. Francis Gray and John W. Reed. Elec. Wld., vol. 73, no. 9, Mar. 1, 1919, pp. 408-412, 6 figs. Development; description of transmission apparatus and air-driven generator.

Artillery Co-Ordinate Computation Charts, S. H. Simpson. Jl. U. S. Artillery, vol. 49, no. 4, Sept.-Dec. 1918, pp. 274-279, 2 figs. Intended to simplify computations involved in trigonometric solutions of triangles.

Probability Chart, George E. Shipway. Jl. U. S. Artillery, vol. 49, no. 4, Sept.-Dec. 1918, pp. 280-285, 1 fig. Devised for determining number of rounds to be provided to destroy target under given conditions of range and gun and also hits that may be expected if a certain number of rounds are fired.

Gas Warfare

Chemical Warfare—A New Weapon, Ellwood Hendrick. Chem. & Metallurgical Eng., vol. 20, no. 4, Feb. 15, 1919, pp. 152-154. Discusses "humanity" and effectiveness of gas warfare.

Mustard Gas. Natural Gas & Gasoline Jl., vol. 13, no. 2, Feb. 1919, pp. 61-62. Part of annual report of Director of Bur. of Mines dealing with this substance.

Gun Forgings

Flaky and Woody Fractures in Nickel-Steel Gun Forgings, Charles Y. Clayton, Francis B. Foley and Francis B. Laney. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 203-237, 59 figs. Information concerning their nature, their effect, and some of the conditions that favor their development, obtained from metallographic examinations undertaken coöperatively by Ordnance Dept., U. S. A., U. S. Bur. of Mines, and U. S. Geol. Survey. Material studied was from different steel plants throughout the country and consisted both of forgings that had been accepted by Ordnance Dept. and those that had failed to pass specified physical tests.

Howitzers

How the 155-Mm. Howitzer Is Made, J. V. Hunter. Am. Mach., vol. 50, no. 7, Feb. 13, 1919, pp. 303-306, 22 figs. Operations on breech-block carrier. Sixth article.

Inspection

How Ordnance Is Inspected, Fred H. Colvin. Am. Mach., vol. 50, no. 7, Feb. 13, 1919, pp. 311-316, 7 figs. Work of small-arms group. Second article.

Machine-Shop Trucks

Machine Shop Trucks Reclaim Guns. Iron Trade Rev., vol. 64, no. 6, Feb. 6, 1919, pp. 376-380, 9 figs. Shops mounted on trucks for repairing of artillery in field. Designed by Ordnance Dept.

Railway Gun Mounts

Railway Gun Mounts, G. M. Barnes. Am. Mach., vol. 50, no. 8, Feb. 20, 1919, pp. 329-325, 14 figs. Description of railway mounts for 8-in. guns, 12-in. sliding mount, 12-in. mortar, 16-in. howitzer and ammuntion cars and locomotives.

Submarines

The Submarine Situation, C. H. Clandy. Sci. Am., vol. 120, no. 9, Mar. 1, 1919, pp. 198-199, 5 figs. British types of submarines, one 340 ft. in length mounting three 4-in. guns and one mounting a 12-in. 50-ton gun.

Transportation

What Our Railway Forces Did in France. Ry. Maintenance Engr., vol. 15, no. 2, Feb. 1919, pp. 55-59, 6 figs. Account of transportation organization and scope of its activities.

See also AERONAUTICS, Aerostatics (Military Balloons), Military Aircraft.

General Science

CHEMISTRY

Antimony Analysis

A Bibliography on the Analysis of Antimony, Elton R. Darling. Chem. Engr., vol. 27, no. 1, Jan. 1919, pp. 11-12 and 21. Articles which have appeared in scientific periodicals arranged alphabetically by authors' names. (Part I, from A to Ke.)

Argon

Specific Weight of Argon (Ueber das specifische Gewicht des Argons), Dr. Hugo Schultze. Zeitschrift fuer Komprimierte und fluessige Gase, vol. 19, no. 1, 1917, pp. 1-3. Mean specific weight for the pure gas, 0.00178371 at 735 m.m. mercury, or 0.001783 at 760 m.m. Coefficient of compressibility between 0 and 760 m.m., 0.00091 at 0 deg. C. Molecular weight referred to 32 for oxygen —39.945. Communication from the Physikalisch-Technische Reichsanstalt.

Colloids

Metals and Alloys from a Colloid-Chemical Viewpoint, Jerome Alexander. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 427-430. Regards them as sponge-like structures, the viscosity or stiffness of which at ordinary temperatures is exceedingly great.

Crucibles, Corrosion of

Action of Alkalies on Crucibles of Platinum and Gold Alloys (Action des alcalis sur les creusets en alliages de platine et d'or), Paul Niclardot and Claude Chatelot. Bulletin de la Société Chimique de France, vols. 25-26, no. 1, Jan. 1919, pp. 4-9. Experiments to determine influence of age on resistance of platinum to alkaline attack, also effect of presence of iridium and similar other metals; tests were extended to gold, silver and palladium alloys.

Glass Analysis

A Contribution to the Methods of Glass Analysis, with Special Reference to Boric Acid and the two Oxides of Arsenic, E. T. Allen and E. G. Zies. Jl. Am. Ceramic Soc., vol. 1, no. 11, Nov. 1918, pp. 739-786, 1 fig. Separation of trivalent and pentavalent arsenic in glasses depends on volatilization of trivial arsenic as A_sF_3 when glass is heated with hydrofluoric and sulphuric acids, while pentavalent arsenic remains in residue. For determination of boric acid Chapin's method is recommended as reliable and accurate.

Radiation

Ionization and Excitation of Radiation by Electron Impact in Nitrogen, Bergen Davis and F. S. Goucher. Phys. Rev., vol. 13, no. 1, Jan. 1919, pp. 1-5, 5 figs. From experiments it is found that radiation can be stimulated in nitrogen molecules by electron bombardment without ionizing them up to about 18 volts when ionization sets in.

Structure of Matter

The Conception of the Chemical Element as Enlarged by the Study of Radio-Active Change. Jl. Soc. Chem. Indus., vol. 38, no. 2, Jan. 31, 1919, pp. 19R-20R. Significance of disintegration and the discovery of elements which differ in their radioactive properties but are chemically identical.

Ultra-Violet Light

Ultra Violet Light in the Chemical Arts, Carleton Ellis and A. A. Wells. Chem. Engr., vol. 27, no. 1, Jan. 1919, pp. 19-20 and 11 ad. Conclusions regarding absorption spectra of

some aromatic compounds; conflicting views concerning spectra of nitro compounds. (Continuation of serial.)

MATHEMATICS

Algebraic Surfaces

On Surfaces Containing a System of Cubics that do not Constitute a Pencil, C. H. Sisam. Am. Jl. Math., vol. 41, no. 1, Jan. 1919, pp. 49-59. Classifies types of algebraic surfaces generated by an algebraic system of given cubic curves so that two generic curves of given system intersect in *x* variable points.

The Classification of Plane Involutions of Order (3). Anna Mamye Howe. Am. Jl. Math., vol. 41, no. 1, Jan. 1919, pp. 25-48. Discusses the different algebraic (1.3) point correspondences between two planes.

On Plane Algebraic Curves with a Given System of Foci, Arnold Emch. Bul. Am. Math. Soc., vol. 25, no. 4, Jan. 1919, pp. 157-161. Suggests method for finding foci of an *n*-ic and illustrates it by applying it to a circular cubic.

Continuous Functions

Continuous Sets that Have No Continuous Sets of Condensation, R. L. Moore. Bul. Am. Math. Soc., vol. 25, no. 4, Jan. 1919, pp. 174-176. Establishes theorem: every bounded continuous set of points that has no continuous set of condensation is a continuous curve.

Derivitiveless Continuous Functions, M. B. Porter. Bul. Am Math. Soc., vol. 25, no. 4, Jan. 1919, pp. 176-180. Proposes simplification of treatment of Weirstrass's and similar functions.

Isoperimetric Problem

An Isoperimetric Problem with Variable End-Points, Archibald Shepard Merrill. Am. Jl. Math., vol. 41, no. 1, Jan. 1919, pp. 60-78, 3 figs. Discusses necessary and sufficient conditions for a maximum (minimum) for a type of problems in the calculus of variations which are related to usual isoperimetric problems, and in which both end-points are allowed to vary along a given fixed curve.

Non-Euclidean Geometry

Quadratic Systems of Circles in Non-Euclidean Geometry, D. M. Y. Sommerville. Bul. Am. Math. Soc., vol. 25, no. 4, Jan. 1919, pp. 161-173. Study of general form $(ph^2+2\,q\,h\,-\gamma) - (h+B)\xi = 0$, where a and b represent distinct fixed lines, and *p*, *q*, *r* are given consonants.

Parabolic Arcs

Comparison of Formulas for Computing Parabolic Arcs, Robert C. Strachan. Eng. News-Rec., vol. 82, no. 7, Feb. 13, 1919, pp. 25, 326, 2 figs. Studies limit of applicability of common formula.

Poincare Surfaces

On Poincaré Surfaces of the Sixth Order (Sur les surfaces de Poincaré d'ordre 6), Pierre Humbert. Comptes rendus des Séances de l'Académie des Sciences, vol. 167, no. 22, Nov. 25, 1918, pp. 776-778. Comment on Liapounov's researches on possible number of Poincaré surfaces in vicinity of critical Jacobian.

Spectral Determination of Functions

Spectral Determination of Functions (Détermination spectrale de fonctions), Michael Petrovitch. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 22, Nov. 25, 1918, pp. 774-776. Determination of $f(z)$ a region of *Z*-plane by one numerical datum.

Volterra's Functions

On Function of Lines and a Set of Curves, Sôichi Kakeya. Sci Reports Tôhoku Imperial Univ., First Series, vol. 7, no. 3, Dec. 1918, pp. 177-196. Discussion of Volterra's functions depending on lines represented by form $y = f(x)$, $\alpha < x < \beta$. Writer attempts to show method of representing function depending on general line.

Weierstrass Formula

On the Evaluation of the Elliptic Transcendents η_1 and η'_2, Harris Hancock. Bul. Am. Math. Soc., vol. 25, no. 4, Jan. 1919, pp. 150-157. Discusses value of Weierstrassian formulæ when applications of general theory are involved or whenever any kind of numerical computation is derived.

PHYSICS

Air

Some Recent Contributions to the Physics of the Air, W. T. Humphreys. Science, vol. 44, nos. 1259 and 1260, Feb. 14 and 21, 1919, pp. 155-163 and 182-188, 6 figs. Feb. 14: Temperatures of air at different elevations; isothermal state of upper air; relation of temperatures to barometric pressures both in summer and in winter; law of wind increase with elevation. Feb. 21: Barometric fluctuations; atmospheric electrical phenomena.

Black Body

A New Experimental Determination of the Brightness of a Black Body, and of the Mechanical Equivalent of Light, Edward P. Hyde, W. E. Forsythe and F. E. Cady. Phys. Rev., vol. 13, no. 1, Jan. 1919, pp. 45-48, 4 figs. Set of values of brightness of black body from 1,700 to 2,600 deg. *K* given on assumption of temperature scale based upon Planck's equation, taking gold point as 1336 deg. *K* and C_2 as 14350 μ deg.; 70_2 candles per cm.² as brightness of black body at 2077 deg. *K* is proposed as absolute standard of light; mechanical equivalent of light for wave length of maximum visibility $\lambda = 0.566\ \mu$ is computed to be 0.00150+0.00005 watts per lumen.

Corbino Effect

Double Induction Balance to Study the Corbino Effect (Doppia bilancia di induzione per lo studio dell' effetto Corbino), Luizi Puccianti. Il Nuovo Cimento, vol. 15, nos. 5-6, May-June 1918, pp. 249-257, 1 fig. Suggests explanation for electro-magnetic effect in a magnetic field.

Crystals

An Apparatus for Growing Crystals under Controlled Conditions, J. C. Hastetter. Jl. Wash. Acad. Sci., vol. 9, no. 4, Feb. 19, 1919, pp. 85-94, 2 figs. Consists essentially of two thermostats, — saturator and crystallizer; saturator is maintained at a temperature slightly higher than crystallizer and is about one-third filled with crystals which keep solution saturated; liquid is pumped from saturator into crystallizer where excess material is deposited into crystals, after which solution is returned to saturator.

Prevention of Columnar Crystallization by Rotation During Solidification, Henry M. Howe and E. C. Groesbeck. Bul. Am. Inst. Min. Engrs., no. 146, Feb. 1919, pp. 361-365, 6 figs. Theory of mechanism of solidification; experiments with strong hot solution of ammonia alum both with quiescent and with rotating solidification.

Reply to Dr. Fulton's Discussion of the Assignment of Crystals to Symmetry Classes, Edgar T. Wherry. Jl. Wash. Acad. Sci., vol. 9, no. 4, Feb. 19, 1919, pp. 99-102.

Sulfur Crystal, F. Russell Bichowsky. Jl. Wash. Acad. Sci., vol. 9, no. 5, March 4, 1919, pp. 126-131, 2 figs. Obtained by mixing a hot alcoholic solution of ammonium polysulfide with a mixture of benzonitrile, hydroxylamine hydrochloride and ether.

X-Ray Analysis and the Assignment of Crystals to Symmetry Classes, Alfred E. H. Tutton. Jl. Wash. Acad. Sci., vol. 9, no. 4, Feb. 19, 1919, pp. 94-99. Criticism of Edgar T. Wherry's memoir on above subject in Jl. Wash. Acad. Sci., vol. 8, 1918, p. 480.

Cyclones

On Travelling Atmospheric Disturbances, Harold Jeffreys. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919, pp. 1-8. Mathematical study of propagation of a cyclone and specially of the conditions which produce the circularity of its isobars.

Diffracting Apertures

On the Radiation of Light from the Boundaries of Diffracting Apertures, Sudhansukumar Banerji. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919, pp. 112-128, 6 figs. Experimental and theoretical analysis of problem. Finds that in all cases in which apertures in focal plane through which rays pass are symmetrically disposed about center of field, this latter being excluded, image of boundary of diffracting surface appears as a perfectly black line surrounded on either side by luminous bands.

On the Theory of Superposed Diffraction—Fringes, Chandi Prasad. Phys. Rev., vol. 13, no. 1, Jan. 1919, pp. 27-33, 4 figs. Shows how principle of superposition suggested by C. F. Brush (Proc. Am. Phil. Soc., 1913, pp. 276-282) may be formulated mathematically and its validity tested in experiment.

Doppler Effect

Experimental Demonstration of the Constancy of Velocity of the Light Emitted by a Moving Source, Q. Majorana. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919, pp. 145-150, 1 fig. Experimental verification of Doppler effect with artificial movement of common luminous source.

Elastic Solids

Deformation Resulting from the Contact of Two Elastic Solids (Sulla deformazione conseguente al contatto di due solidi elastici), Elena Mannei. Il Nuovo Cimento, vol. 15, nos. 5-6, May-June 1918, pp. 171-179. Study of Hertz' discussion of problem. (Gesammeldte Werke, vol. 1, pp. 154-169.)

Elastostatics

A Problem in the Elastostatics of a Semi-Infinite Solid, Kwan-ichi Terazawa. Sci. Reports Tôhoku Imperial Univ., First Series, vol. 7, no. 3, Dec. 1918, pp. 205-215, 7 figs. Distribution of normal pressure on boundary of a semi-infinite elastic solid.

Electromotive Forces

Reciprocal Relations Following from Kirchhoff's Laws (Relations de réciprocité découlant des lois de Kirchoff), J. B. Pomey. Revue Générale de l'Electricité, vol. 5, no. 3, Jan. 18, 1919, pp. 83-87, 4 figs. Mathematical equations establishing relations between electrical, mechanical and kinetic magnitudes in network of conductors. Derived for various arrangements and distributions. Supplementary to writer's study of electromotive forces in branches of network. (See R. G. E. vol. 4, Aug. 3, 1918, pp. 131-132.)

Electrons

On the Mechanical and Electrodynamical Properties of the Electron, Megh Nad Saha. Phys. Rev., vol. 13, no. 1, Jan. 1919, pp. 34-44. Investigation of scalor and vector potentials of moving electron, electric and magnetic fields due to a moving electron, Maxwell's stresses, law of attraction between two moving electrons and equations of motion of the electron, by Minkowski's method of four-dimensional analysis.

Gas Equations

Molecular Attraction and Attraction of Mass, and Some New Gas Equations, James Kam. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919, pp. 65-97, 2 figs. Deviations from gaseous laws lead to establishing that cohesive forces are proportional to the square of molecular weight and obey inverse square law; thus an analytical value is derived for the tensile strength of iron which is of same order as experimental value.

The Laws of Perfect Gases in Relation to the Theory of Heat (Sulle leggi dei gas perfetti in relazione alla teoria del calore), M. Ascoli. Il Nuovo Cimento, vol. 15, nos. 5-6, May-June 1918, pp. 212-220, 1 fig. Derivation of general differential of thermodynamic changes from the gas equation and also from the first thermodynamic law.

Hydrodynamics

Integral Invariant of Hydrodynamics and Its Application to the Theory of General Relativity (Sur un invariant intégral de l'Hydrodynamique et sur son application à la théorie de la relativité générale), E. Vessiot. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 27, Dec. 30, 1918, pp. 1065-1068. Concerning Einstein's hypothesis on nature of fluids.

Induction Coils

The Optimum Secondary Capacity of an Induction Coil, E. Taylor Jones. Elecn., vol. 82, no. 2122, Jan. 17, 1919, pp. 99-101. A mathematical article.

Interferential Contact Lever

Interferential Contact Lever Experiments Relating to the Elastics of Small Bodies, Carl Barus. Proc. Nat. Acad. Sci., vol. 5, no. 2, Feb. 1919, pp. 44-49, 9 figs. Apparatus designed by writer in which interferential contact lever measures strain corresponding to stress imparted by pushing springs.

Mercury-Vapor Light

The Light From Mercury Vapor, C. D. Child. Lond., Edinburgh & Dublin Phil. Mag., vol. 37, no. 217, Jan. 1919, pp. 61-64, 1 fig. Comparison of writer's experiments with similar experiments by Strutt (Proc. Roy. Soc., 1917, A. 94, p. 88) on the luminous vapor coming from discharge through gases at low pressure.

Thermal Conductivities

Thermal Conductivity of Various Materials, T. S. Taylor. Phys. Rev., vol. 13, no. 2, Feb. 1919, pp. 150-151. Table of values for hard rubber, white fiber, various species of wood, solid and powdered graphite and lamp black.

Tuning Forks

A Method of Comparing Tuning Forks of Low Frequency and of Determining their Damping Decrements, Albert Campbell. Proc. Phys. Soc., Lond., vol. 31, part 2, Feb. 15, 1919, pp. 87-89. Method consists in putting windings of maintaining magnets in series with each other and with a sensitive vibration galvanometer; beats are shown by pulsations of band of light on scale.

Welsbach Mantle

Physical Study of the Welsbach Mantle. Engineer, vol. 107, no. 2769, Jan. 24, 1919, pp. 100-103. Develops the physical theory of the Welsbach mantle.

X-Rays

Energy of the Characteristic X-Ray Emission from Molybdenum and Palladium as a Function of Applied Voltage, Benhamin Allen Wooten. Phys. Rev., vol. 13, no. 1, Jan. 1919, pp. 71-86, 5 figs. It was found that in molybdenum α and β radiation appeared at 19.2 kv. and in palladium at 24 kv.; ratio of intensity of α line to that of β line was found to become constant as voltage increased for each metal; absorption coefficients for wave lengths of α and β lines of molybdenum and palladium in glass and in molybdenum and palladium respectively were determined.

The Right Man in the Right Place in the Army

By LT.-COL. JOHN J. SWAN,[1] U. S. A., WASHINGTON, D. C.

The Committee on Classification of Personnel in the Army, Adjutant General's Department, Washington, D. C., has recently arranged an exhibit to show how the army brings the job and the man together, and how the methods thus employed can be applied with profit to industrial management. The exhibit, which consists chiefly of charts and photographs, has already visited a number of cities, and has been received with great enthusiasm. The address abstracted below was delivered at a meeting of the New York Section of The American Society of Mechanical Engineers, on February 24, 1919, and will afford those who have not been able to visit the exhibit an opportunity to acquaint themselves with this interesting and important phase of the Army's work.

THE organization of a modern army covers nearly every field of human endeavor, and one is therefore not surprised to learn that even now vague ideas exist regarding the purpose and duties of many of the Government's war-time departments. In order that the work of the Personnel Department of the Army might be properly understood and appreciated, the Committee on Classification of Personnel, under the Adjutant General and with his authority, has prepared a special exhibit, which is arranged to acqnaint one with the various steps involved in "making a soldier," from his arrival at the camp to the time when he begins training; and again through the steps of assignment, transfer, and shipment from the camp to service overseas. The magnitude of this work can perhaps be judged from the statement that approximately 3,700,000 men had to be interviewed, enrolled, equipped and assigned.

The men coming into the camps represented every conceivable type—men with special technical education, skilled tradesmen, and workers of all degrees of ability. The necessity for conserving the skilled workmen early became apparent to the Personnel Department, for it was found that many specialists and skilled tradesmen of certain types were rare. Of 425,000 men received in the draft up to December 15, 1917, reduced to the basis of 10,000 white and averaged over the entire country, it was found that there were only 50 bakers, 90 blacksmiths, 8 bridge carpenters, 90 butchers, 190 cooks, 150 electricians, 8 farriers and a small representation of the other trades essential to the operation of the Army. These figures are based on the statements of the men themselves as interviewed by the Personnel Officers, but when the men claiming these trade abilities were examined or tested by the system employed by the Personnel Department it was found that only 6 per cent were experts, while 24 per cent were journeymen, 40 per cent apprentices, and 30 per cent without any experience whatsoever.

These figures thus bring out very forcefully the vital necessity of the system employed in the Army to detect such skilled men and place them in organizations where their skill was required. Without this system skilled men of all kinds would have been consumed in the early days and none left for subsequent Army extension; industry would also have been robbed, and to such an extent that the flow of munitions could not have been maintained.

Methods of Classification

The process of "making a soldier" is illustrated diagrammatically in Fig. 1. This is a routing diagram showing the stages in enrolling the recruits and transforming them into fully equipped soldiers. The black line is the path of all the men. The first step is the receiving and checking of draft papers, and the ne t an interview to obtain the recruit's record for his Qualification Card. This card, shown in Fig. 2, was made out for every man in the Army. The third step is the Oral Trade Test to check the statements of those claiming trade ability, and this is followed by the checking and sterilizing of clothing for storage, pending final acceptance or rejection, and a shower bath as preparation for the medical examination. The civilian clothing of men accepted was sent home or given to the Red Cross, in accordance with the desires of the man, and the clothing of those discharged was transferred to the Discharge Section of the building, to be ready for the men as they passed out at the far end.

The actual medical examination requires several rooms, the first being for dental and orthopedic examinations, and also for obtaining the height and the weight; and the next for examinations for skin afflictions, mobility of joints and other details. A third room is necessary for psychiatric examinations or those to check the mental alertness or intelligence; then follow in order the genito-urinary, primary tuberculosis, heart and circulation, nose, ear and throat, and eye examinations.

In the medical examinations up to this point, men with varying degrees of perfection have been found, and on leaving the eye room the stream is split, those having been found physically fit for any class of military service continuing along the path of the heavy line, and those giving evidence of any fundamental defects following the path of the light line for a secondary review. After this second examination these men are placed in one of two classes, Class B, those who have "remediable defects" requiring hospital treatment, and those known as Class D men, who are unquestionably unfit for any class of military service. These two classes follow the light line through the Development Battalion Review Board room and the Discharge Section, through the dressing room where they receive back their civilian clothes, and finally they are given any pay to which they may be entitled, and transportation.

Men classified by the Camp Surgeon as Class C-1 and C-2 men, and illiterates, are also passed through the Development Battalion Review Board room where a special group of medical and personnel experts give each case careful consideration, and then they go back into the line of accepted men, indicated, however, as men for "limited service" only, and for assignment to Development Battalions. All men then pass through the finger-print, scars and body-mark room, and next to the Quartermaster Section, where they are measured for clothing and shoes; then along the counter where they receive underclothing, outer clothing and other equipment and are permitted to dress. Next they pass forward to the record room where the equipment issued to them is recorded, and then on through the mustering-in room where they are interviewed for service records. In the next section applications and instructions with regard to insurance and allotments are prepared, and this is followed by an inspection of all the various papers accumulated by each man in his passage through the system, to see that they are correct and complete. Finally the men are vaccinated and inoculated and then definitely assigned to a company or organization as soldiers ready to begin military training.

As already mentioned, Fig. 2 illustrates the front and reverse side of the soldier's Qualification Card used in registering information in regard to enlisted men. This card was one of the credentials of every man, and moved with him wherever he went. The card gives the essential facts in connection with each man; his occupation, trade skill, previous experience, former employer, nativity, citizenship, schooling, linguistic ability, mental capacity, physical capacity, leadership ability, military experience, and kind of service preferred, together with subsequent military assignments. These cards are not filled out by the recruits themselves but by an interviewer who obtains from each man the information required. The card is also used to classify the men under certain standard trade-name headings or occupations essential or desirable within the Army, as it records the man's prime occupation, secondary and tertiary occupations, and length of time engaged in each.

[1] Personnel Branch of Operations Division, General Staff. Mem. Am. Soc. M. E.

When the card is completely filled out the interviewer places a tab on the top of the card above the line of numbers. These numbers indicate the line in which the man can be classed. If he is "skilled" they are marked by green tabs, and if "partially skilled" or apprentice, by an orange tab.

The cards thus tabbed enable a quick selection of men of special ability, and also permit a rapid compilation of data for

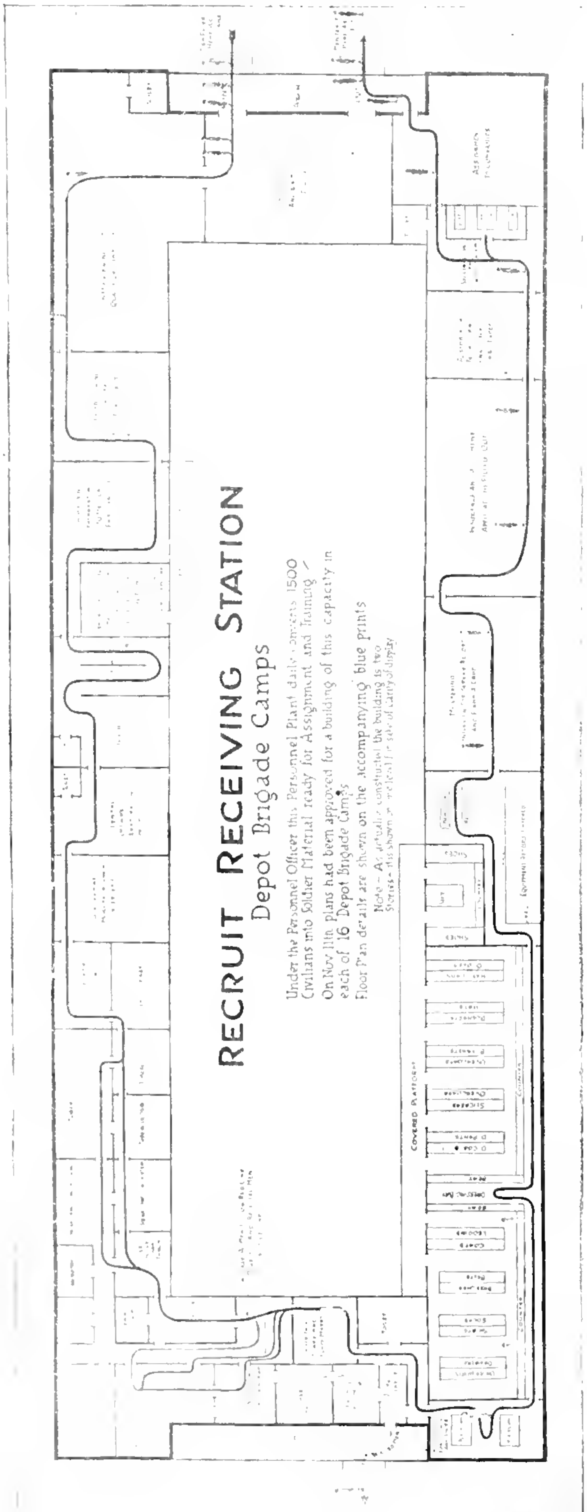


Fig. 1 Recruit Receiving Station

reports to the Central Office in Washington regarding the total numbers of men of various trade or professional ability within the camp, and available for transfer to other units or organizations.

At regular intervals a detailed tally of the cards of all unassigned drafted recruits in the camp was made and a report of totals of men under the standard occupational headings, and whether journeymen or apprentice, was forwarded to the Central Personnel Office in Washington.

Fig. 3 is a page from the Army Trade Specifications, and shows three of the 714 occupations in the Army classification system. The preparation of this list involved a very thorough detailed study of all of the organizations within the entire Army and an analysis of all of the trades or types of men required in such organizations. It represents the standard which was employed throughout the Army to designate trades and occupations. In other words, the mere statement that a man is a blacksmith is not sufficient, as the meaning of this term differs in different localities and in different industries. In the Army system, the general heading "Blacksmith" is required as a group heading and it is subdivided to cover various types of blacksmiths, and each of these types has a special name and a symbol. By the use of these specifications it is possible for any one desiring to requisition tradesmen to determine just what type of man is desired by examination of the specifications and then call for such man, using the standard name and symbol. The occupational list and trade specifications thus form the common language employed throughout the entire Army organization, and were the basis of the personnel classification employed.

The Clearance or Allotment Section of the Central Personnel Office was in Washington, and each week this office received an Occupational Report from all camps or draft receiving depots. The data on these separate reports were posted or consolidated in what were known as Supply Books under the headings of locations and trades. The Supply Books, therefore, gave the total supply of skilled men of all kinds in the camps and depots of the country.

The demand for skilled men came from the technical staff corps and the divisions being formed, and upon the receipt of a requisition by the Allotment Section the requirements stated thereon were examined with regard to the nearest camps or available supply of men as shown by the Supply Books, and an Allotment Sheet made out in which was stated the camps from which the supply was to be filled, and the number and kinds of men to come from each. From this Allotment Sheet a series of formal orders was made out, one for each camp or depot. With the completion of the Unit Allotment Sheet, which is presumed to cover all details of the requisition, separate Adjutant General orders were made out for each of the camps from which men were to be drawn. The Personnel Officer at the camps receiving "through channels" the regular order for transfer proceeded to issue the necessary camp orders and made out a "report of transfer," a copy of which was returned to the Allotment Section, so that actual shipment could be checked against its order.

All of the foregoing sounds exceedingly simple, but it requires great care and accuracy in order that mistakes be avoided and it is in this connection, and particularly because of the close coöperation between the Central Personnel Office in Washington and the Personnel Organization in the various camps, that it was possible to reduce the time of organization of a division from the nine months required in the early stages to three months toward the end, and also to effect more thorough organization in the shorter time.

Approximately 3,700,000 men of all sorts were thus carded and classified and requisitions were received and orders issued for the disposal of approximately 1,200,000 men, distributed as follows:

General Service	865,058
General Service—Colored	180,412
Limited Service—White	59,294
Army Schools, White and Colored	89,058
Special Draft (P. M. G.)	56,009
Induction Authorized	161,663

The method of recording information with regard to officers was, broadly speaking, exactly the same as in the case of enlisted men. When it is considered that there were approximately 195,000 officers in the Army at the close of the war, some slight idea can be gained of the necessity of being able instantly to locate or select officers of various experiences and abilities in

order to organize or reorganize infantry or technical units. In the case of officers, however, inasmuch as considerable additional information was required over that for enlisted men, the card was made larger. On these cards were recorded in a systematic manner and uniformly, history, education, experience and all other data to afford a clear picture of each individual officer. The original card was filed with headquarters of the particular unit with which the officer was connected. A duplicate card was filed in the Central Personnel Office at Washington or at headquarters overseas, and as officers were ordered overseas copies of the cards went with them in order that the system might operate efficiently with the fighting forces.

Rating of Officers

In the past, officers were selected or promoted by seniority or on the basis of personal judgment of some superior. When the Army was small and there were relatively few officers, this system, though not ideal, was used with a fair degree of satisfaction. However, with the rapid inflow of new material necessary to meet the tremendous expansion of the Army, it was impossible to employ such a system, and it became evident that some standard method must be devised which would insure accuracy of results and impartial treatment to all.

To meet this condition the Central Personnel Organization at Washington put into effect a Rating System devised by Walter Dill Scott, Director of the Committee on Classification of Personnel in the Army. Starting with the Officers' Training Schools, this system was put into effect step by step until now it covers the entire Army and is the standard system employed for selecting and promoting officers here and overseas.

Briefly, the system is based on giving to each officer a rating which is made by his immediate superior and which rating is determined quarterly so that the improvement or change in the officer's work or ability can be credited at frequent intervals.

The system consists of each rating officer preparing for himself a scale of measurement in accordance with a simple yet effective method which can be understood by all and is universally applicable. This scale considers separately the essential qualifications of the officer, such as physical qualities, intelligence, leadership, personal qualities and general value to the service, and the rating officer considers such officer whom he has to rate in the light of these qualifications one by one as contrasted with the officer on his scale.

In preparing his scale for rating any group of officers under his command, he thinks of the purely physical qualities of all officers of his own rank with whom he is acquainted and visualizes the physique, bearing, neatness, voice, and endurance of each, irrespective of any other qualities. Among all those he has in mind, some one will stand out preëminently and he writes down the name of this particular officer as highest. Another one will rank slightly lower, still another about average, another low, and finally one will be visualized as being lowest in the quality named.

In a like manner he then selects five officers on the basis of their intelligence, another five for their leadership, others for their personal qualities, and finally those whom he believes to be of value to the service.

The rating officer then has a scale under five general headings with five names under each heading ranged from highest to the lowest with purely arbitrary factors of value opposite each name. It should be noticed that in the preparation of this scale it makes no difference whether a general or first lieutenant has worked it out, for in the preparation of the scale any conscientious officer can do this who has considered essential qualities and has made up his scale ranging from highest to lowest of men of his own rank with whom he is personally familiar.

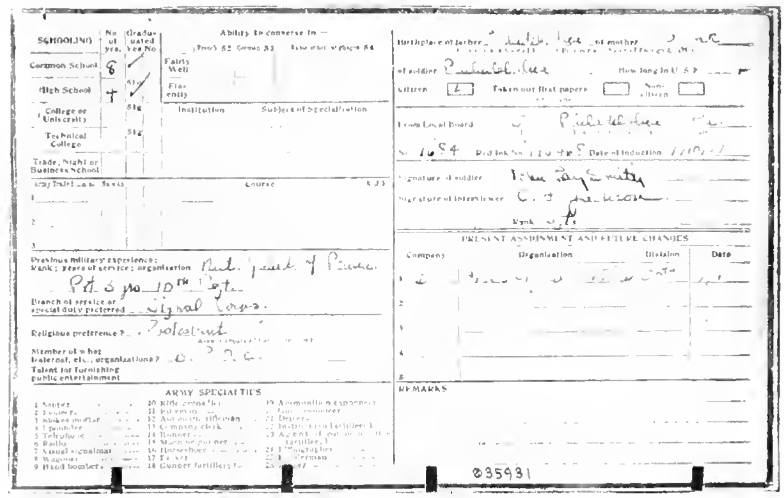

Fig. 2b Details of Soldiers' Qualification Card (Back)

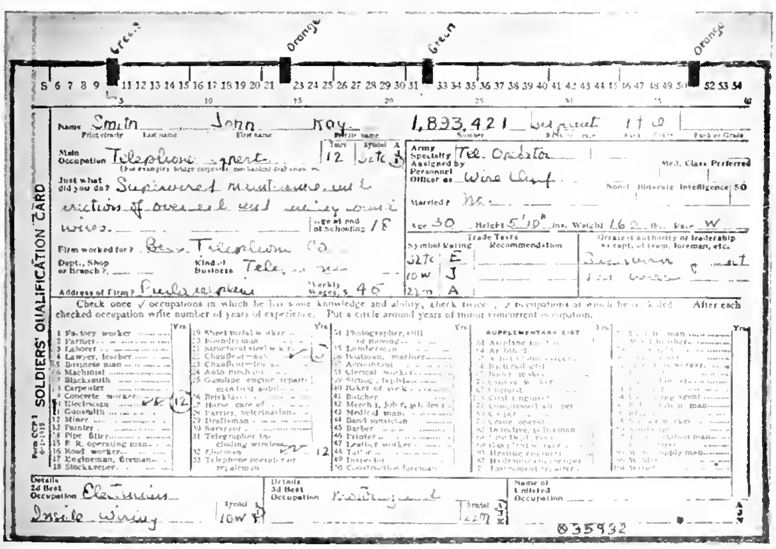

Fig. 2a Details of Soldiers' Qualification Card (Front)

In the application of the scale the reverse process is followed. If, say, a captain has to rate a number of lieutenants, he proceeds to take each and analyze him quality by quality, for the moment forgetful of all other elements of his make-up. For instance, he considers first his physical qualities, he compares him one by one with the various individuals whom he has listed in his scale. If he has the quality of the highest in the physical class, he credits that lieutenant with the highest factor; if comparable with the average man of the scale, he gives him the average factor; if lowest, the lowest factor. Having done this, he forgets completely the physical qualities and takes those of the next quality named in the scale and compares him one by one with the scale names.

In this way all officers are rated on the fine points in an orderly, logical and systematic manner, and as far as humanly possible prejudice or preference has been eliminated and the rating given each is comparable to officers of like rank no matter where or by whom rated. However, as a further safeguard the details and final rating in each case are checked by each rating officer's immediate superior.

The results obtained for October 1918 in the case of a number of large camps show that the rating officers have given average ratings of from 58 to 62, and this experience has shown to be about correct.

Psychological Tests

The results obtained through the use of various psychological tests adopted in the Army to check the intelligence or mental

alertness of men, both commissioned and enlisted, are most interesting and valuable. Some of these are shown in Fig. 4.

At the upper left side of the figure is shown a chart indicating the average intelligence of officers in the various arms of the service, the plain white indicating A and B intelligence rating, the shaded portion C+, and the black section those below C+. The chart is ranked in order of degree of A and B rating, C+, and below C+. It will be noticed that it grades Engineers at the top, with practically all A and B intelligence ratings, and a very small proportion of C+, increasing in the lower rating rather gradually, with the veterinary group at the bottom. In the latter the tests developed that of those tested about one-half were of A and B intelligence rating and one-half of C+ and below.

The lower chart on the left-hand side shows results obtained in testing the intelligence rating of men undergoing training in the Fourth Group of Officers' Training Corps. These are placed in order of highest intelligence, with Camp Lewis leading and Camp Wheeler at the bottom of the list at the time these tests were made.

The chart at the lower left center illustrates the utility of intelligence tests as applied to a group of Officers' Training Camps and Non-Commissioned Officers' Schools, the upper diagram being the summary of 1375 officer candidates. It will be noticed that the heavy vertical lines A, B, and C+ are practically all above the horizontal line, but indicate that almost without exception officer candidates having intelligence ratings of A, B, and C+ prove successful. In almost as nearly striking manner the lines C, C– and D, indicating men of lower intelligence ratings, extend below the horizontal one into the region of those who proved failures.

This chart indicates in a general way that, barring a few exceptions in a neutral zone, it would have been possible in the first instance to select candidates by some form of intelligence test, and thereby practically double the capacity of the training camps. The diagram in the lower half of the chart indicates in like manner the result obtained with the 1458 non-commissioned officers, and in this the same argument holds.

The chart at the lower right center indicates results of intelligence tests in connection with special groups, the upper diagram showing 465 promotions of various sorts, indicating that where men were "recommended for promotion" they were, to a very large extent, men of higher intelligence. The "assignment to special duty" in the case of 785 men tested, shows a similar result, although in this case the percentage of men of high intelligence is not so large. The lower line covers the test of 491 men who had been subjected to discipline for one reason or another. Here is strikingly shown the fact that low intelligence is a very serious factor; conversely, it would be assumed that with the increase of intelligence the number of disciplinary cases would decrease.

The chart at the upper right-hand side very clearly indicates the wide difference in the average intelligence of various companies making up the 319th Infantry Regiment. The height of the line for each company above the horizontal line varies from 3 to 30 per cent of men of A and B intelligence rating. The percentage of illiterates or foreigners below the line varies from 9 to 60 per cent. It will be noticed in Company A, the percentages of intelligence and illiteracy nearly balance. In Company C, however, there are only 3 per cent of the men of a high intelligence rating and 38 per cent low. It is seen from this that if a definite schedule for training had been prepared, calling for certain work to be accomplished in a definite period of time, and assuming company commanders to be of equal ability, it would be impossible for Company C to develop as far as Company E. The chart shows the importance of endeavoring to equalize the various companies in any organization, at least in the first instance. It is appreciated that when an organization gets into actual combat service, exigencies will arise which prevent carrying out any ideal system, but in the first instance, when organizations are being formed or built up and trained, such matters can receive attention.

The chart at the lower right-hand side affords a comparison of the enlisted personnel of the various arms in the 34th Division. In this division the Sanitary Detachment was first in the matter of intelligence, the Engineers being found further down the line.

B

FAMEK 7-fm **FORGING MACHINE OPERATOR**

DUTIES
1. Operation of standard types and various kinds and sizes of forging machines, such as bulldozes and hydraulic presses on general work.

QUALIFICATIONS
2. Should have thorough knowledge of rivet and bolt forging machines, screw, toggle and hydraulic presses for heading staybolts, forms, and all classes of press forgings of various materials.
Should have a practical knowledge of coal, gas, and oil types of forge furnace, and the proper heating of various material for forgings.
Must be able to set and adjust dies and maintain same and be able to turn out uniformly dimensioned product.

SUBSTITUTE OCCUPATIONS
3. Drop forge operator, press operator, heavy forge blacksmith, blacksmith. 55

HADGA 7-he **HEAT TREATER**

DUTIES
1. Heat treatment in general of steel forgings, finished parts and castings.

QUALIFICATIONS
2. Must be thoroughly experienced in the heating and oil treatment of various grades of steel for annealing or toughening for any kind of work. Must be capable of annealing, quenching and drawing of all kinds of steel forgings and castings, either rough or after being machined. Must be capable of judging temperature by the eye, and familiar with the use of pyrometers.
Must thoroughly understand the construction and operation of standard types of coke, oil, gas or electric furnace equipment, and quenching tanks, and have a working knowledge of the metallurgy of steel, at least sufficient to know how it should be heated, treated and cooled, under instruction or by test.
Should have had similar experience in forge shop of any industrial plant.

SUBSTITUTE OCCUPATIONS
3. Annealer, heater, forge heater. 56

HAEWS 7-h **HORSESHOER**

DUTIES
1. Shoeing horses and mules.

QUALIFICATIONS
2. Must be a practical horseshoer, capable of forging, shaping and punching horse or mule shoes from standard stock or bar material. Capable of removing shoes, paring and dressing hoofs, welding caulks, shaping shoes for correction of diseased or malformed feet.
Should have some veterinary knowledge, enabling him to care for and correct hoof troubles.
Must be able to handle and shoe unbroken horses under rough field conditions, and handle heavy horses and mules.
Should have some knowledge of blacksmithing and be able to make welds and do light blacksmith work.
Experienced as commercial horseshoer or as horseshoer in construction camp, or employee of company having considerable stock.

SUBSTITUTE OCCUPATIONS
3. Farrier, country blacksmith, blacksmith. 35928 57

Fig. 3 Page of Army Trade Specifications

Trade Tests

In describing the Recruit Receiving Station, mention was made of Trade Tests to check the verbal statements of men claiming trade ability. A very interesting and important side of Personnel Work in the Army has been the development and introduction of these tests into the camps and depots receiving draft men. Owing to the diversity and number of trades encountered, a very thorough study was required in determining whether tests could be applied and if so what character of tests were necessary.

As a result three forms of Trade Tests were developed, sometimes applied singly and again two or all three used. The first of these is the "oral trade test," in which the candidate or recruit is asked a series of standardized questions which have been prepared with the greatest care to eliminate ambiguity and localisms or catch features. A trained interviewer or tester asks the questions exactly as printed and in accordance with simple but very definite rules, and the recruit answers to the best of his

ability. For the benefit of the tester, the correct answer, or several answers if more than one is possible, are given under the questions. If the recruit answers correctly he is given a maximum score. If his answer is partially correct in accordance with a definite schedule, he is given a partial score. After all of the questions have been answered and scored by the tester, the total is taken and compared with the rating scale, which scale gives the terms Novice, Apprentice, Journeyman and Expert within certain numerical limits. In other words, in the case of the tailor's test, a score of from 18 to 37, inclusive, would give the recruit a rating of Apprentice; 42 to 56, inclusive, Journeyman; and 59 and above, Expert.

The second form of the test is known as the "picture test," and employs pictures of certain essential tools or devices of the trade with which a man who has or can perform in the trade must be familiar. In this test a sheet of numbered pictures is given to the recruit and the tester holds a corresponding question sheet with questions and answers corresponding to the numbered pictures. The recruit must name the various tools or appliances and the tester scores up and gives a rating as in the former case.

Post 3 round a curve. The scorer then tells him to back up to Post 2. This little preliminary run indicates whether the recruit can drive a car at all, and gives evidence of sufficient ability to proceed with the remainder of the test. It also gives the man a familiarity with the throttle and gearing and "feel" of the particular machine to be tested. The scorer then instructs him to drive on to Post 4 and turn to the left and enter the S or reverse-curve section outlined by vertical post or stakes. He is instructed to drive through this S at whatever speed he regards as best and must not stop nor drive in a jerky, irregular manner, and he must not knock down any stakes. In emerging from the reverse curve to the large square he is required to drive close up and with his hood at the center of the board at station 5. The scorer then instructs him to back away and around the semi-circle section to the second square and continue backing until the tailboard is close up to and in the center of the board 6, which is supposed to represent a loading platform. He is then told to run forward close to Post 7, where he stops on the grade, and then start and run up to the top of the grade, turning around with no more than one backing and without stalling engine or grinding gears,

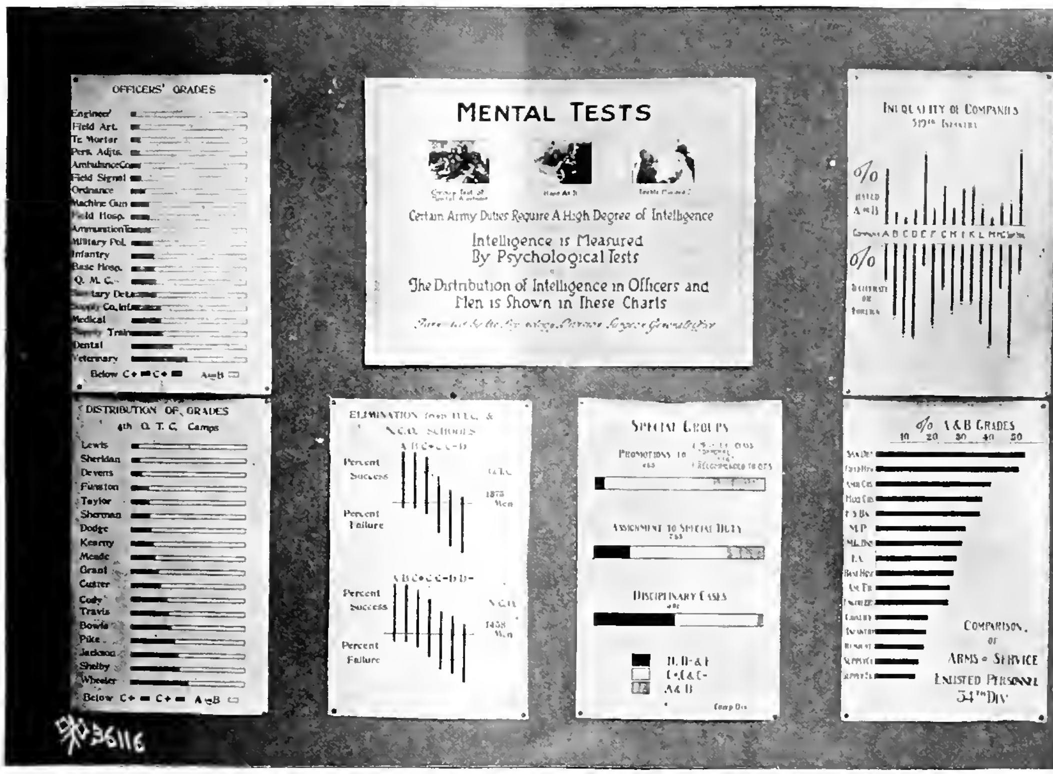

Fig. 4 Results of Psychological Tests

The third and last test consisted of an actual demonstration of the recruit's abilities. In the case of truck or auto drivers a course was laid out and each candidate was required to perform certain definite operations in a definite sequence and under identical conditions. If in doing this work he fails to perform all of the operations or does certain other things against which he is warned, he receives less than a perfect score. As in the former cases, totaling the scores gives a figure which enables the man to be rated as a Novice, Apprentice, Journeyman, or Expert.

In operation, the system is as follows: A recruit having claimed more or less ability as a truck driver when being interviewed in the first instance, is given an oral Trade Test, and provided he is classed by the interviewer as an apprentice, journeyman or expert in this, he is ordered to present himself at the performance-testing station at a definite time. On arrival at the testing station or truck course he takes command of a standard truck with a tester or scorer on the driver's seat with him to give instructions and score him for results.

The scorer instructs him to drive up to Post 1, which is the start of the test. He is then told to drive to Post 2 and on to

and then to run down the incline to the starting point. Careful instructions are given and all candidates are treated alike. It will be seen that the conditions of this test are very exacting, and it has been found that any man who gets a score of Journeyman or Expert in the test can subsequently make good under any conditions of service.

In accordance with the plans 92,550 truck drivers, 36,000 motorcycle drivers and 30,000 automobile drivers were needed overseas. These tests effected an enormous saving in maintenance and repairs because valuable transportation equipment was not turned over to inexperienced or incompetent men to be wrecked in a few hours, but was put in the hands of men proved to be skillful both in operation and care of their equipment.

The motorcyclist's test and the auto driver's test are in principle the same with varying details, inasmuch as conditions of practical operation vary somewhat from the truck driver's. It is interesting to note that these tests are at least in principle the rebirth of a system employed by the French in the very early days when automobiles were just beginning to appear in France, which was really the pioneer in automobile use. The municipal

authorities in Paris, and later in other continental cities, and still later in a few instances in the United States, employ practical tests of this sort before issuing licenses to drivers.

Carpenters were in great demand and to obtain these men the following test was employed: The recruit receives a blueprint or working drawing with dimensions and full instructions as to what is required in the finished piece. The material and tools are standard throughout and wherever the tests are conducted. The work to be performed consists in ripsawing a slab from one side of a 2-ft. piece of 2 x 4 rough scantling, in chopping with a carpenter's hatchet on one edge, planing of one face and edge and chiseling a smooth dovetail mortise at one end of the piece, all in accordance with the dimensions in the instruction print. The particular job has been prepared after extensive study with an idea of requiring a minimum amount of material and reasonable time, and yet to permit the fundamental operations required of a general carpenter, such as ripsawing, chopping, planing, chiseling, squaring, working to dimensions from a drawing or blue print, etc.

The tester is provided with a definite system of marking, scoring or crediting, so that each man is judged on what he has done in accordance with the standard system. This would give him the same rating regardless of where he performed his work, or by whom he was judged. In other words, in this test, and all of the trade tests, the fundamental criterion has been that the method of administering the test, scoring, and rating would be such that a man tested at any of the trade-test points and receiving a rating would have received exactly the same test at any of the other testing points.

Tests were also devised for linemen, patternmakers, inside house wiremen and blacksmiths, and since these trade tests were instituted about 250,000 soldiers have been tested.

These tests also emphasize the fact that it is not possible to accept a man's statement of his trade ability, for while the majority of men endeavor to tell the truth, each man's judgment of his own ability is nevertheless not comparable with any definite standard.

Briefly, the steps necessary in giving trade tests are:

1 The procurement of the necessary information
2 The preparation of questions on the basis of this information
3 The test of data and the revision of such questions or tasks
4 The second revision
5 The practical tryout to insure the value of the various questions for checking trade ability
6 A further analysis and check
7 The preparation of the tests in final form for practical use
8 The accumulation of further information bearing on results of the tests with the idea of improving them if it is thought necessary.

The foregoing is but a brief review of the general work which has been conducted by the Committee on Classification of Personnel in the Army. It is hoped that it will in some small way afford a clear and logical picture of classification as employed in the Army at the time the armistice was signed. It is sincerely hoped that this work, which was in a large degree responsible for the rapid and efficient organization of the Army, will not be permitted to lapse, but will be further perfected and carried forward, and as time goes on become a complete and permanent part of the Army Establishment.

Peat and Its Uses

Attention is called by the Department of the Interior, in a recent bulletin, to the vast undeveloped peat deposits in the United States, and to the many possible uses of peat. In northern Europe it is used for fuel and as the basis for many manufacturing industries. Gas, charcoal, coke, and a number of valuable by-products are produced from it. Owing to the scarcity of raw materials in Europe, peat and peat moss are also employed as substitutes for absorbent cotton in the preparation of surgical dressings, for wood, and for cotton and woolen cloth. In the United States peat is utilized chiefly as fertilizer and fertilizer filler, as stable litter, and as an absorbent for the uncrystallized residues of beet- and cane-sugar refineries in the manufacture of stock feed. The shortage of coal in the Eastern and Central States that began toward the end of 1917, however, has stimulated a wide interest in the potentialities of peat as a source of auxiliary fuel.

The following information concerning the features of peat as fuel has been gathered and published by the United States Geological Survey:

Peat in an undrained bog contains about 90 per cent of water, which must be reduced to 30 per cent before the peat can be used for fuel. By thoroughly draining the deposit, approximately 10 per cent of the original water contained in the peat may be eliminated, but the remainder which is held in the microscopic plant cells and minute intercellular spaces, cannot be reduced below 70 per cent without drying in the open air or in a heated chamber. No process of artificial drying has been developed as yet which can be considered as in any way one that is commercially feasible.

The value of a given deposit of peat as a source of fuel is dependent upon many factors, most important of which are degree of decomposition, heating value, and ash content. The maximum quantity of ash that is usually considered allowable in peat for commercial use has been placed at between 20 and 25 per cent, but if it exceeds 20 per cent of the total dry weight the peat is not considered worth the labor of production.

The comparative calorific value of peat and other fuels is given by the following figures:

	B.t.u.
Wood	5760
Air-dried cut peat	6840
Air-dried machine peat	7290
Lignite	7500
Bituminous coal	14000
Anthracite	13000

Cut peat is bulky, is easily crushed, and burns rapidly with considerable waste; it is superior to wood in heating value but is unfitted for commercial use. Machine peat is suitable for both domestic and industrial use. Powdered peat is well adapted for use under steam boilers with forced draft; for open grates this fuel is nearly ideal, and peat may be burned in the same stoves as coal and wood.

The machinery for the preparation of machine peat consists essentially of an excavator and a macerator. In principle and form the latest types of peat machines are similar to the pug mill or grinding machine for plastic clay. After being thoroughly macerated the peat is shaped into compact blocks as it comes from the machine. Machine peat which is allowed to dry slowly contracts into a dense mass covered by a gelatinous, skinlike substance called hydrocellulose. After the moisture has been reduced to about 25 per cent, this coating renders the machine peat impervious to water, even when immersed.

Powdered peat is prepared by reducing the moisture content to about 25 per cent and pulverizing the resulting material. It is said that when powdered peat is blown with compressed air into the furnace, ignition is almost instantaneous, the peat forming a gas which gives a uniform fire throughout the entire combustion chamber.

The value of peat, however, lies in its distillation rather than its combustion, and on these lines it could supersede wood in the production of acetic acid, methylated spirits of ammonia and tar. In the process of distillation peat requires larger retorts than coal, and of a design which facilitates the transmission of heat from the surface toward the center. Experiments have shown that revolving retorts produce the best results; the rotary movement of the retorts insures uniform carbonization in a short time and at a relatively low temperature.

To enable the gas arising from the carbonized peat to pass out of the retorts, the hollow shaft of each is perforated so as to provide a passage from the inside of the retort to a collecting chamber in the axis of the pivot and thence to the stills for fractional distillation. The distillation takes about forty minutes for retorts holding a ton of peat and making six revolutions per minute.

Electrical Measurement of Fluid Flow in Pipes

Theory and Development of a Device Embodying an Ammeter and Watt-hour Meter and in Which the Electric Current Flowing is Proportional to the Quantity of Fluid Passing Through the Pipe

By JACOB M. SPITZGLASS,[1] CHICAGO, ILL.

DESPITE the fact that the science of mechanical engineering is much older than that of electrical engineering, its methods of measurement are nevertheless in many respects much behind those afforded by the latter. A striking example of this is found in a comparison of the methods of measuring fluid motion in pipes and the flow of an electric current. The instrument used for the electric current is simple and direct-reading, and while there have been many excellent devices adopted for measuring the flow of fluids in pipes, it has been quite generally agreed that an instrument similar to the ammeter or wattmeter would be of great value.

Recently the writer had the privilege of experimenting with a flow-measuring device in which these instruments are applied. Measurement is accomplished by means of an electric current which is so regulated by the differential pressure of the flow that it represents the amount of fluid passing through the pipe.

The main features of the device are shown diagramatically in Fig. 1. The U-tube, partly filled with mercury, is made to balance the impact pressure of the flow in the pipe by the rise of mercury in the low-pressure side of the tube. The mercury column also forms a part of the electric circuit, as shown in the figure. This electric circuit contains a fixed external resistance R_1 in series with a variable internal resistance R_2, a constant electromotive force E, an ammeter A and a watt-hour meter W. In the contact chamber C, which forms the low-pressure side of the U-tube, there are a number of conductors of varying length placed above the mercury column, and as the mercury rises it makes contact with one conductor after another. The variable resistance R_2 is subdivided by these conductors into resistance steps corresponding to the varying length of the conductors, so that the rise and fall of the mercury column varies the amount of resistance and thereby regulates the amount of current passing through the circuit.

The basic principle of the device accordingly involves the laws governing the flow of fluids through pipes along with those governing the flow of an electric current. The problem of establishing the theoretical relation between these fundamental laws offered little difficulty because of the similarity between the units of flow measurement, such as pressure and velocity, and the units of electric measurement, such as voltage and current. On the other hand, the attempts to apply the theory to a working model were beset with numerous difficulties, and the obstacles that were overcome during the long period of experimental work presented many problems which are briefly dealt with in later paragraphs.

Units of Flow Measurement

The relation between the pressure and velocity of fluids in its simplest form is represented by the well-known equation

$$\frac{v^2}{2g}\delta = P_2 - P_1 = hw$$

or

$$v = \sqrt{\frac{2g(P_2 - P_1)}{\delta}} = \sqrt{2gw}\sqrt{\frac{h}{\delta}} \quad \text{. . . . . [1]}$$

where v and δ represent the velocity and density of the fluid; $(P_2 - P_1)$ the equivalent differential pressure; h the height and w the density of the liquid column balancing the differential pressure of the flow.

This differential pressure hw may be obtained, as shown in Fig. 2, either directly by balancing the difference between the dynamic and static sides of a pitot tube inserted in the line, or indirectly by balancing the difference between the high- and low-pressure sides of a venturi tube, nozzle tube or orifice plate. In the case of the pitot tube, the differential column in the U-tube represents the flow or motion existing at the given section of the line, but in the venturi tube, nozzle or orifice, the column obtained represents the *change* of motion produced by the artificial obstruction of the passage at the given section of the pipe.

In any case, however, the relation between the differential column thus obtained and the velocity of the fluid in the pipe may be represented by Equation [1], provided there is introduced

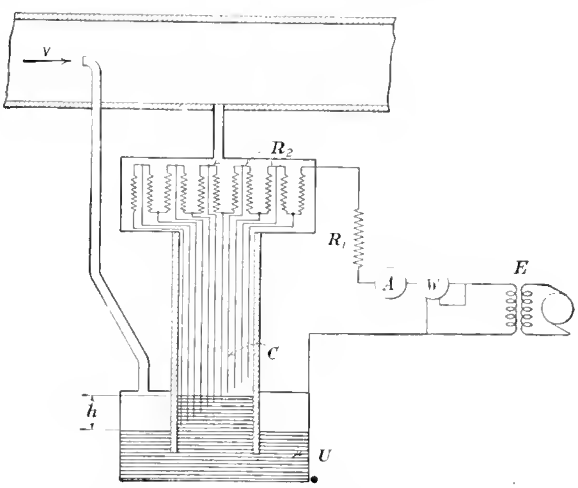

Fig. 1 Diagrammatic Sketch of Author's Electrical Device for Measuring Flow of Fluids in Pipes

the experimental coefficient derived for the given tube or orifice. Thus in general,

$$v = C\sqrt{2gw}\sqrt{\frac{h}{\delta}} \quad \text{. . . . . [2]}$$

The volume of the fluid Q passing per unit of time through an area A is given by the equation

$$Q = Av = AC\sqrt{2gw}\sqrt{\frac{h}{\delta}} \quad \text{. . . . . [3]}$$

the corresponding weight G per unit of time is

$$G = Q\delta = (A\sqrt{2gw})C\sqrt{h\delta} = KC\sqrt{h\delta} \quad \text{. . . . . [4]}$$

and the total weight S for a given period of time t is

$$S = Gt = KCt\sqrt{h\delta} \quad \text{. . . . . [5]}$$

Units of Electric Measurement

Having adopted the foregoing general equations for the flow of fluids, the corresponding electric measurements may be covered by the following definitions:

I = current in amperes flowing through the electric circuit of the measuring device. The instrument was designed so as to have one ampere represent the maximum capacity of the meter

E = electromotive force of the circuit. A uniform pressure of 40 volts was selected to represent the average density of the fluid measured

Wt = amount of electric energy expended in the circuit of the device in a period of time t

R = total resistance of the circuit in ohms.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. All papers are subject to revision.

[1] Vice-President and Consulting Engineer, Republic Flow Meters Co., Mem.Am.Soc.M.E.

F = rate of flow in the pipe corresponding to the electric current in the circuit, or the ratio of G to I. F is the "indicating factor" of the flow meter.

T = total amount of flow or weight of fluid corresponding to the electric energy passed through the circuit. T is the ratio of S to W, and is designated as the "totalizing factor" of the flow meter.

Since by definition $FI = G$ and from Equation [5] $G = KC \sqrt{\delta}\sqrt{h}$, therefore $FI = KC\sqrt{\delta}\sqrt{h}$, or

$$I = \frac{KC}{F}\sqrt{\delta}\sqrt{h} \quad \text{[6]}$$

The value of K is constant for any given set of conditions as determined from Equation [4]. The value of C, depending upon the particular design of the tube or orifice, is also constant for any given case.

To find the value of F, let $I_{max.}$ be the current in amperes corresponding to the maximum capacity of the meter, $G_{max.}$, which in turn corresponds to the maximum differential column $h_{max.}$ From Equation [6]:

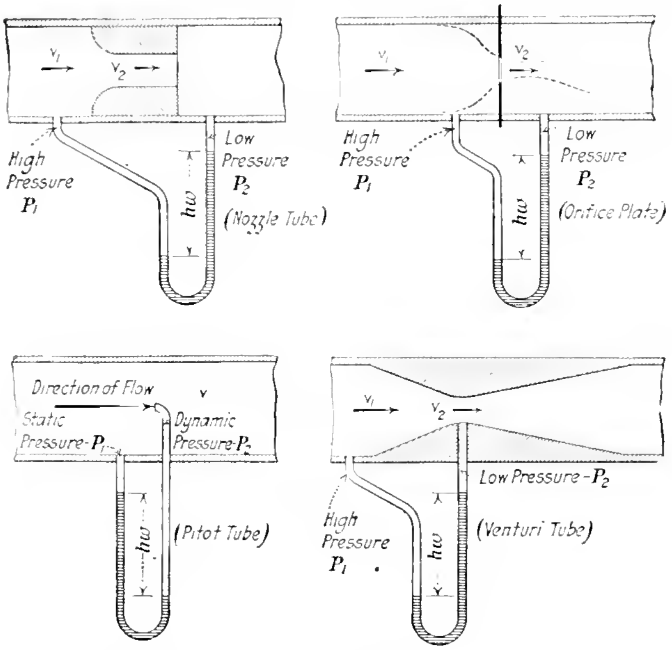

FIG. 2 METHODS OF DETERMINING VELOCITY PRESSURE

$$I_{max.} = \frac{KC}{F}\sqrt{\delta}\sqrt{h_{max.}} \quad \text{[7]}$$

whence

$$F = KC\sqrt{\delta}\frac{\sqrt{h_{max.}}}{I_{max.}} \quad \text{[8]}$$

and since $I_{max.}$ is equal to unity,

$$F = KC\sqrt{\delta}\sqrt{h_{max.}} \quad \text{[9]}$$

The quantity $\sqrt{h_{max.}}$ is called the characteristic or the scale of the given meter and it determines the capacity of the meter, depending upon the amount of differential column $h_{max.}$ which the meter is able to develop and record.

Combining Equations [6] and [9],

$$I = \sqrt{\frac{h}{h_{max.}}} \quad \text{[10]}$$

It is interesting to note that $h/h_{max.}$ represents the relative value of the differential column for a given rate of flow, and $100\ h/h_{max.}$ is the percentage variation of the head in any given meter. From Equation [10] it follows that in order to represent the amount of flow, the current I should be numerically equal to the square root of the relative height of the mercury column in the U-tube of the meter. From the same equation,

$$h = I^2 h_{max.} \quad \text{[11]}$$

That is, the height of the column for a given flow is numerically equal to the constant $h_{max.}$ times the square of the current flowing through the circuit.

From Ohm's law ($E = IR$) we obtain by substitution

$$R = E\sqrt{\frac{h_{max.}}{h}} \quad \text{[12]}$$

That is, the resistance R in the circuit should be numerically equal to the voltage divided by the square root of the relative height of the differential column.

It remains to determine the value of T, the "totalizing factor" of the instrument, or the ratio of S to W. Since $Wt = EIt$ and by definition $TWt = S = Gt = FIt$, therefore

$$T = \frac{F}{E} \quad \text{[13]}$$

That is, the totalizing factor of the meter is equal to the indicating factor divided by the voltage in the circuit.

Fig. 3 shows diagrammatically the relation of the units involved in the electric measurement of the flow. The parabolic curve to the right shows the variation of the current in the electric circuit representing the capacity of the flow and corresponding to the percentage variation in the differential column balancing the velocity pressure of the flow. This curve represents the solution of Equation [11]. The hyperbolic curve to the left of the diagram shows the relation between the current and the corresponding resistance at the given voltage of the electric circuit. The solution of Equation [12], or the relation of R to h, is obtained indirectly by following from a given value of R on the resistance curve to the corresponding value of h on the current-and-capacity curve.

It will be observed that the diagram does not include the first 10 per cent of the flow capacity inasmuch as this represents only 1 per cent of the differential column, which is as low as a practical device is able to measure with any degree of accuracy. This disadvantage, however, is offset by the fact that the scale of the flow meter can be so chosen that the desired measurements will fall within the active part of the scale.

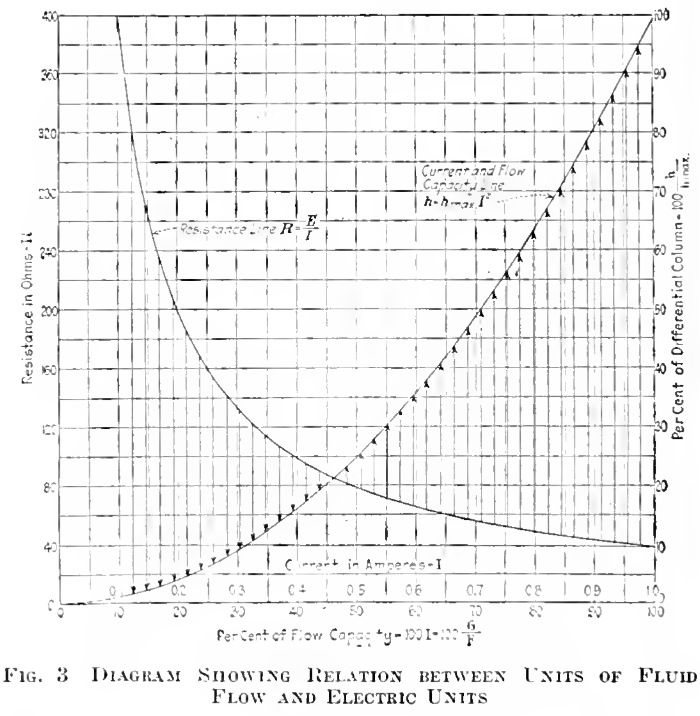

FIG. 3 DIAGRAM SHOWING RELATION BETWEEN UNITS OF FLUID FLOW AND ELECTRIC UNITS

PRACTICAL APPLICATION

After the relations between the various factors had been determined, the problem reduced itself to the construction of a resistance which would be regulated by the differential column of the flow according to the solution of Equation [12]. The first attempt in this direction was made by inserting a continuous

resistance coil in a water manometer where the height of the water column would reduce the amount of resistance in the coil by short-circuiting the part immersed in the water. The first trials were made with direct current, and while it was anticipated that electrolytic action would be set up between the metal conductors and the water, it was nevertheless expected that this action would not take place when alternating current was used.

There was little information available on the subject and it was therefore necessary to determine experimentally the amount of resistance needed. After obtaining some idea of the amount required and being hindered by the accumulation of deposit in the container, which was at first attributed to the electrolytic action of the direct current, provisions were made to continue the experiments with alternating current. It was discouraging, however, to note that practically the same action took place between the metal conductors and the water when alternating current was used. Repeated analyses of samples of the deposit disclosed that it was a formation of oxide, due to the corrosion of the metal conductors in contact with the water.

Besides the formation of deposits, there were other disadvantages in short-circuiting the metallic resistance by a water column. On one hand the conductivity of the water varied with its hardness, thus introducing a variable resistance in the part of

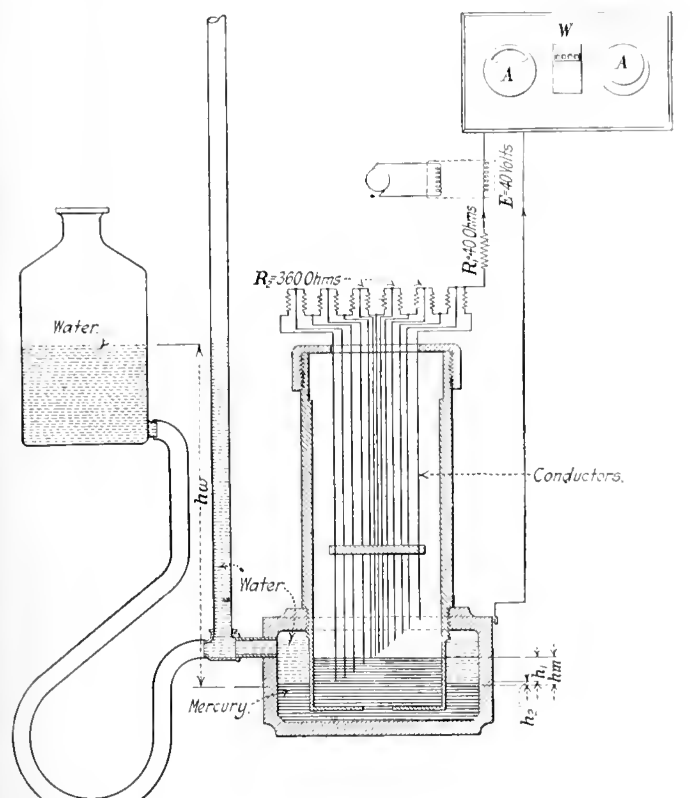

FIG. 4 DEVICE IN WHICH RISE OF MERCURY COLUMN REGULATES AMOUNT OF CURRENT

the column which was covered by water, and on the other the vapors formed over the surface of the water had a tendency to short-circuit the resistance coils, again introducing a similar variable in the portion of the column above the level of the water. When repeated attempts to eliminate these defects had failed it was decided to adapt mercury instead of water for the regulating column of the instrument. The use of mercury, however, necessitated radical changes in the form of the device. The effective column of mercury for the average velocity pressure would be too small to cover the continuous resistance coil and produce the desired regulation of the resistance. It was therefore found necessary to regulate the resistance by steps through conductors coming in contact with the top of the mercury column. Fig. 4 shows the elementary form of experimental device adapted for this purpose.

In this elementary device the successive conductors were divided into steps of equal height from the zero level of the mercury column. The electromotive force of the circuit was maintained constant at 40 volts. The resistance of the circuit, which amounted in all to 400 ohms, was subdivided by the contact rods into 40 consecutive steps, and the amount of resistance provided for each step was determined from Equation [12]. Using these values the maximum current of 1 ampere corresponded to the minimum resistance of 40 ohms, while the minimum current of 0.1 ampere corresponded to the maximum resistance of 400 ohms.

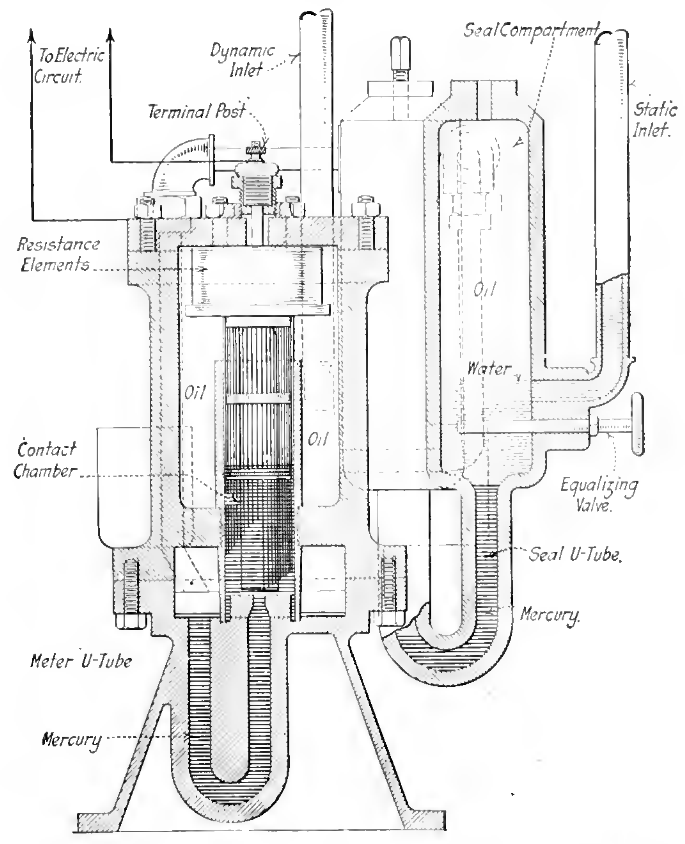

FIG. 5 LATEST TYPE OF AUTHOR'S FLOW METER WITH MERCURY SEAL

Between these limits the rise and fall of the mercury column produced by the variation of the head on the high-pressure side of the U-tube would vary the amount of resistance in the circuit in accordance with the hyperbolic curve shown on the left of Fig. 3, thereby regulating the amount of current passing through the circuit in accordance with the parabolic curve on the right of the figure.

The operation of the elementary device was successful from the very start, but only as long as the contact chamber was kept free from water did the regulation of the current correspond with the variation of the head or the height of the mercury column. On the other hand, the instrument when equipped with an oil seal and connected to a pitot tube in the steam line could not be made to operate properly. When left under pressure the oil would leak through the fiber plug and allow water to get into the contact chamber, which would immediately put the instrument out of order.

To overcome this action the body of the instrument was extended to include also the resistance coils attached to the contact rods and the circuit completed through a plug connecting the internal and external resistances together. This change eliminated the leakage of oil from the instrument, but still the water could not be kept out of the chamber for any length of time. In some cases the water would blow through the mercury as soon as the pressure was admitted to the instrument. It was thought at that time that a bypass valve connecting the static and dynamic tubes when the pressure is admitted to the instrument would eliminate this trouble. After many changes in the original design an instrument

was made which for a short period of time was used as a steam-flow meter. In this instrument, besides the equalizing valve, an additional overflow chamber was provided to keep the water from reaching the conductors over the surface of the mercury. A terminal post replaced the connecting spark plug, thus allowing an adjustment of the position of the conductors with respect to the level of the mercury column. These additions, however, did not entirely eliminate the possibility of water coming in contact with the resistance elements of the device. With a uniform flow in the pipe the operation of the instrument would continue for some time, but when a slight disturbance of pressure occurred in the line it would cause the water to blow through the mercury into the contact chamber and this would immediately discontinue its operation.

Notwithstanding this objectionable feature, the convenience of the electric measurement of the flow and the fact that the instrument would function as long as there was no water in the contact

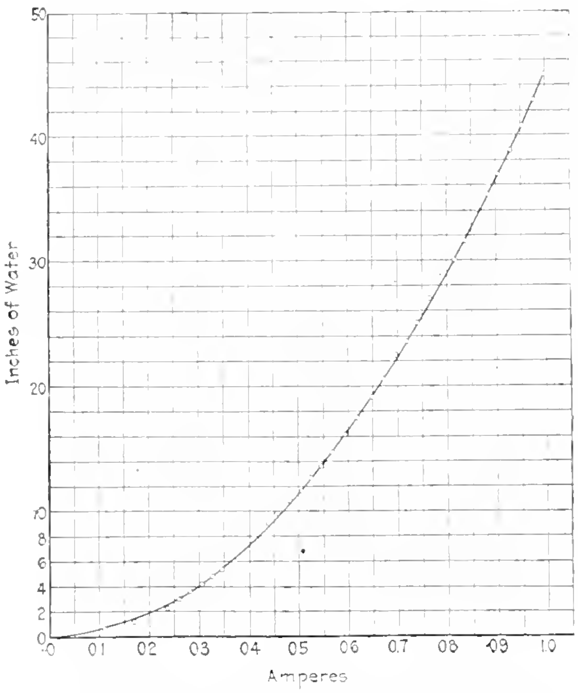

Fig. 6 Comparison of Curve Obtained from Equation [11] with Data Plotted from Table 1

chamber, have encouraged further experimenting for the elimination of defects. The problem was finally solved in the fall of 1917 by the addition of a mercury seal connected in parallel with the working base of the instrument. The function of the mercury seal in this case is quite similar to that of a fuse plug in an electric circuit, with the added advantage that it is self-replacing. The principle of its operation is illustrated in Fig. 5, which shows a section of the meter body and seal chambers. It can be seen that the U-tube joining the two compartments of the seal will contain a column of mercury about one-half the height of the column in the meter body. Under normal operation the mercury column in the seal acts in unison with the mercury column in the meter body and does not interfere with the proper transmission of the differential pressure in the meter. When, however, some disturbance of pressure occurs in the line sufficient to break the seal, the mercury spreads over the larger area of the compartment, equalizes the pressure in the two compartments in the same manner as would an automatic opening of a bypass valve, and thus prevents the breaking of the higher column in the U-tube. As soon as the abnormal differential pressure is released, the mercury drops back into its place and reëstablishes the necessary seal between the two compartments. In this model a large quantity of oil is trapped in the two compartments of the seal and in the meter body, eliminating the possibility of water blowing through the mercury and coming in contact with the resistance elements of the meter.

In the latest type of the flow-measuring device the contact rods were changed from their former equal spacing above the zero level to spaces varying in height so as to give at each step equal increments of current representing equal amounts of flow. This was accomplished by gaging the length of the contact rods to follow the parabolic curve shown at the right in Fig. 3, which represents the solution of the equation $h = I^2 h_{\max}$. In the actual gaging of the contact rods $h_{\max.}$ is taken as the distance between the zero level of the mercury and the end of the contact rod showing the maximum flow. The successive heights of the rods for the given equal increments of current are determined more conveniently by differentiating Equation [11], $h = I^2 h_{\max}$. The first differential, or $dh = h_{\max.}\ (2IdI + dI^2)$, represents the respective increments of h corresponding to the given increments of I. The second differential, or $d^2h = 2h_{\max.}dI^2$, represents the respective difference in the successive increments of h, from which it is noted that the distance between the successive contact rods is increased uniformly by the constant quantity $2h_{\max.}dI^2$.

Testing for Accuracy

The accuracy of a flow-measuring device is necessarily made up of two factors. One is the accuracy with which the device registers the differential pressure equivalent to the flow in the pipe, and the other is the accuracy with which it will indicate or record this differential pressure or the equivalent units of flow. In the usual application of the flow meters, where the pitot tube, the venturi tube, or the orifice plate is used for obtaining the differential pressure of the flow, the efficiencies of these devices have been determined by numerous tests and are at present well known. Their nature is such that a given flow will always produce the same effect under the same conditions, since they do not possess any working parts to vary the relative effectiveness of their operation. On the other hand, the indicating or the recording elements of such devices may vary from time to time depending upon the condition of the moving parts in these elements. It is necessary, therefore, to have convenient means for testing them in order to ascertain their accuracy at frequent intervals.

Table 1 gives the data of a typical test on the resistance element of the flow-measuring device, showing the relation between the differential column and the corresponding readings of the electric current.

TABLE 1 DATA OBTAINED FROM TEST OF AUTHOR'S ELECTRIC FLOW-MEASURING DEVICE

(E_1 = 112 volts)

The Design of Riveted Butt Joints

Simple General Equations for Use in Design, Derived from Schwedler's Graphical Method

By ALPHONSE A. ADLER,[1] BROOKLYN, N. Y.

In this paper Schwedler's graphical method of designing riveted joints is analytically treated by the author, who states the fundamental assumptions employed and submits brief evidence for their justification.

A general equation is derived to determine the pitch in any row, and another to determine the efficiency in ideal cases. The design of cover plates is also considered.

Actual joints are calculated, using commercial dimensions, and the close agreement found between the ideal and calculated efficiencies seems to indicate that the scheme of analysis is consistent. The design of a quadruple-riveted joint furnishes the data for the single-, double- and triple-riveted joints by simply omitting the extra rows of rivets.

In the design of riveted joints certain assumptions are made the justification of which is ascertained from their agreement with the results of experiments. Among the more important of these assumptions are the following:

a The tensile resistance of the joint is directly proportional to the net area under stress

b The shearing resistance of the joint is directly proportional to the total cross-sectional area of the driven size of rivets

c The bearing resistance of the joint is directly proportional to the total projected area of the driven size of rivets

d There is no bending stress in the rivets

e The frictional resistance of the joint is independent of the strength.

Of the foregoing, the first assumption is perhaps the one which involves the greatest discrepancy. This subject was studied by Coker[2] by means of an optical method. A perforated plate of xylonite was placed between the polarizer and analyzer of a pair of Nicol prisms. By this means Coker showed the intensity of stress around the rivet hole. An analytical treatment of this problem was given by Suyehiro[3] and his results show fair agreement with those obtained experimentally by Coker. Suyehiro further shows that if the hole in a plate is plugged, the resultant stress around the rivet hole is very much less. In the latter case it corresponds to a riveted joint when the rivets are driven, as only in this case can the plate be loaded. The stress intensity between the rivet holes, nevertheless, is not uniform.

Assumptions *b* and *c* are common in structural and machine design and are dealt with at length in the more important texts on strength of materials.

Assumption *d* is also common in structural design. Since the rivet completely fills the hole and the plates are comparatively rigid, there is little chance for bending and hence the bending stress is negligible.

The last assumption forms the basis of another method of designing joints the advantages of which are pointed out by Bach[4]. Briefly stated, joints in this country are designed for strength and checked for tightness, while in the method proposed by Bach the procedure is reversed and quite different from that in the former case.

After all, if actual joints are riveted up and tested to destruction, the data so obtained yield the maximum values of the stresses in tension, shear and bearing. If these values are then used in actual designs the process becomes reversible and errors made originally in the assumptions are automatically canceled. Indeed, this is the general plan followed in structural design today. For the limited sizes of plate and rivets used in boiler joints it should give results sufficiently reliable to inspire confidence. However, additional experimental data will always be useful.

Analytical Treatment

As is customary in riveted-joint design, the shearing resistance of a rivet is equated to the crushing resistance in order to find the smallest permissible diameter of rivet. Hence if d is the diameter of the rivet in inches, f_s' the shearing resistance in lb. per sq. in. per single surface in double shear, f_c' the crushing (or bearing) resistance in lb. per sq. in. in double-shear bearing, and t the thickness of the plates connected in inches,

$$\frac{\pi d^2}{2} f_s' = dtf_c' \qquad [1]$$

from which

$$d = \frac{2tf_c'}{\pi f_s'} \qquad [2]$$

In other words, if d is chosen in accordance with Eq. [2] the rivet is equally likely to fail in shear or crushing because of the condition imposed in equating the shearing and bearing resistances.

For reasons to follow, assume a strip of plate of width w inches to be bent around the rivet somewhat like the link of a chain but of rectangular cross-section. If the resistance of this link under tension is equal to either the shearing or the crushing resistance of the rivet and if R denote this resistance,

$$R = 2wtf_t$$

or

$$w = \frac{R}{2tf_t} \qquad [3]$$

where f_t is the tensile resistance of the plate in lb. per sq. in.

The idea of conceiving a plate to be divided into hypothetical tension strips the resistance of each of which is equal to the strength of a rivet, first occurred to Schwedler,[1] who used it as the basis of a graphical method. Unwin[2] has applied this method to boiler joints, but it is cumbersome and does not lend itself to slight changes in the assumed data without entailing a comparatively large amount of effort. An attempt to avoid this led to an analytical treatment which was published by the writer in 1916.[3] It was found later that the steps in this analysis could be concisely expressed by simple general equations, and these are the subject of this paper. A sufficient part of the article referred to is repeated here in order to insure continuity of treatment.

Fig. 1 shows a single-riveted joint in which the cover plate nearest the observer has been removed for convenience. The tension strips are shown around the rivet. The portion between the tension strips (shown shaded) could be cut out of the plate without impairing its strength. Of course in an actual boiler this could not be done, since this metal is required to enclose the contents.

Fig. 2 shows a commercial quadruple-riveted joint with the distance between the rivet rows greatly exaggerated and in which the rivets are not staggered. The tension strips are numbered for convenience. It will be found that, starting below with any strip, it may be traced around a rivet and back again, thus showing that each strip has a particular rivet the resistance of

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. All papers are subject to revision.

[3] *Power*, August 1, 1916.

which it adds to the total resistance of the joint. The problem therefore rests on finding the maximum resultant strength.

If w is the width of a strip and d is the diameter of the rivet, then from Fig. 1 the most economical pitch for the first row of rivets occurs when the tension strips just touch each other. Denoting this pitch by p_1,

$$p_1 = 2w + d \;\ldots\ldots\ldots\ldots\ldots\ldots [4]$$

The shaded area is metal available for rivets in subsequent rows. Thus in each pitch there is available a strip of width d. If m_1 represents the available metal per inch, then

$$m_1 = \frac{d}{p_1}$$

But since the amount of metal required to insert extra rivets in

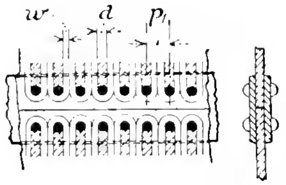

FIG. 1 SINGLE-RIVETED BUTT JOINT

a second row is a strip of width $(2w + d)$, the pitch of the second row is

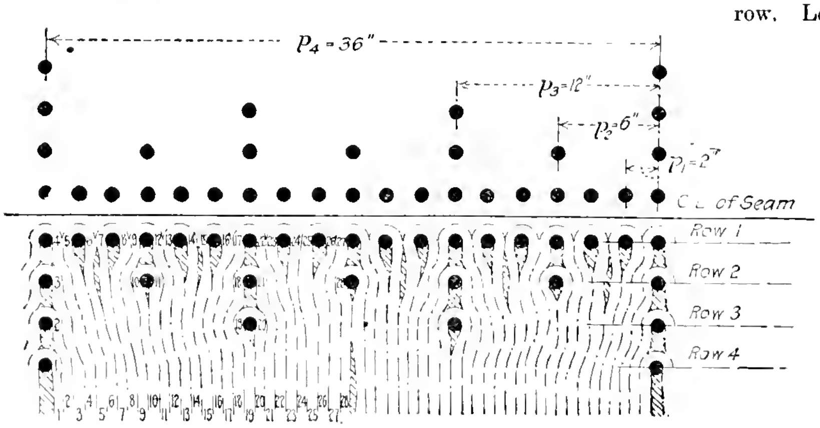

FIG. 2 LAYOUT OF A QUADRUPLE-RIVETED BUTT JOINT

$$p_2 = \frac{2w + d}{m_1}$$

Since, however, from Eq. [4] $p_1 = 2w + d$ and $m_1 = \dfrac{d}{p_1}$, the pitch p_2 may be written

$$p_2 = \frac{p_1}{d \div p_1} = \frac{p_1^2}{d} \;\ldots\ldots\ldots\ldots\ldots\ldots [5]$$

Similarly, there is available for rivets in a third row a width of metal d in each distance p_2, or the width of available metal m_2 from the second row per inch of width of seam is

$$m_2 = \frac{d}{p_2}$$

Hence the pitch of the third row is

$$p_3 = \frac{2w + d}{m_2}$$

and replacing the values of numerator and denominator as before,

$$p_3 = \frac{p_1}{d \div p_2}$$

But since p_2 is given in terms of p_1 by Eq. [5], this substitution results in

$$p_3 = p_1 \div \frac{d}{p_2}$$

$$= p_1 \div \frac{d}{p_1^2 \div d}$$

or

$$p_3 = \frac{p_1^3}{d^2} \;\ldots\ldots\ldots\ldots\ldots\ldots [6]$$

In the same manner

$$m_3 = \frac{d}{p_3}$$

$$p_4 = \frac{2w + d}{m_3}$$

$$= p_1 \div \frac{d}{p_3}$$

$$= p_1 \div \frac{d}{p_1^3 \div d^2}$$

or

$$p_4 = \frac{p_1^4}{d^3} \;\ldots\ldots\ldots\ldots\ldots\ldots [7]$$

Therefore it will be seen in Eqs. [4], [5], [6] and [7] that the subscript of p in the left-hand member is the same as the exponent of the numerator p_1 in the right-hand member and is one greater than the exponent of d in the denominator. For a general equation, let n signify the number of the row; then it follows that

$$p_n = \frac{p_1^n}{d^{n-1}} \;\ldots\ldots\ldots\ldots\ldots\ldots [8]$$

To try a simple check, the equation should hold for the first row. Let therefore

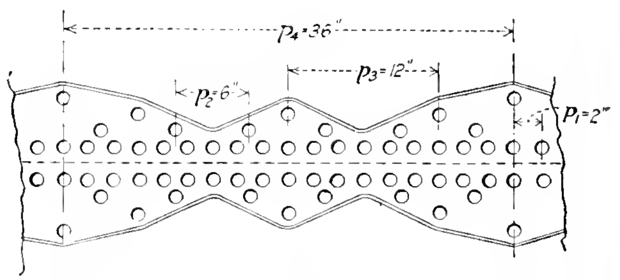

FIG. 3 SCALLOPED COVER PLATE FOR QUADRUPLE-RIVETED JOINT

$$p_1 = \frac{p_1^1}{d^0}$$

or

$$p_1 = p_1$$

which as it stands conveys little information; but recourse to Eq. [4] shows it to be equal to $2w + d$.

A general equation for the efficiency of a Schwedler joint is also possible. Thus, in an ideal joint all manners of failure are equally likely. Choosing the most convenient form for the equation, take the case for the efficiency in tension of the last row, namely:

$$e_n = \frac{(p_n - d)\,tf_t}{p_n t f_t}$$

$$= \frac{p_n - d}{p_n}$$

$$= 1 - \frac{d}{p_n} \;\ldots\ldots\ldots\ldots\ldots\ldots [9]$$

As p_n becomes very large by increasing the number of rows, the efficiency approaches unity or 100 per cent.

A slightly different form might be obtained for the general equation of the efficiency. Since p_n in Eq. [9] may be replaced by its value from Eq. [8],

$$e_n = 1 - \frac{d}{p_1^n \div d^{n-1}}$$

$$= 1 - \frac{d^n}{p_1^n}$$

$$= 1 - \left(\frac{d}{p_1}\right)^n \;\ldots\ldots\ldots\ldots\ldots\ldots [10]$$

This equation expresses the same result as Eq. [9]. For example, the ratio d/p_1 is always less than unity, and the fraction raised to any positive power will approach zero as n becomes large. Again, the efficiency approaches 100 per cent as the number of rows is increased.

For high-efficiency joints the cover plates must be designed from fundamental principles rather than from the empirical rules given in certain textbooks. On the plate the tension strips must all pass through the last row of rivets. On the cover plates the condition is just the reverse, that is, the strips all pass through the first row of rivets. Since the pitch and tensile stress are fixed, the required area of metal may be obtained by suitably determining the thickness.

The total load on a strip of plate of width p_1 is

$$\frac{p_1 t f_t e}{100}$$

where e is the actual efficiency of the joint in per cent. The resistance of two cover plates is

$$2\ (p_1 - d)\ t_c f_t$$

where t_c is the thickness in inches of one cover plate. For equal strength these must be equated; hence

$$2\ (p_1 - d)\ t_c f_t = \frac{p_1 t f_t e}{100}$$

from which

$$t_c = \frac{p_1 t e}{200\ (p_1 - d)} \quad \ldots\ldots\ldots\ldots\ldots\ldots [11]$$

Application of the Method

Assume a plate ½ in. thick. Let f_t = 60,000 lb. per sq. in., f_s' = 45,000 lb. per sq. in., and f_c' = 100,000 lb. per sq. in. From Eq. [2],

$$d = \frac{2 \times \tfrac{1}{2} \times 100{,}000}{\pi \times 45{,}000} = 0.707 \text{ in.}$$

The value of R in Eq. [3] is obtained from the shearing or bearing resistance in Eq. [1]. Thus for shear,

$$R = \frac{\pi \times (0.707)^2 \times 45{,}000}{2} = 35{,}300 \text{ lb.}$$

From Eq. [3]

$$w = \frac{35{,}000}{2 \times \tfrac{1}{2} \times 60{,}000} = 0.588 \text{ in.}$$

Then from Eqs. [4], [5], [6] and [7]

$$p_1 = (2 \times 0.588) + 0.707 = 1.883 \text{ in.}$$

$$p_2 = \frac{(1.883)^2}{0.707} = 5.03 \text{ in}$$

$$p_3 = \frac{(1.883)^3}{(0.707)^2} = 13.4 \text{ in.}$$

$$p_4 = \frac{(1.883)^4}{(0.707)^3} = 35.7 \text{ in.}$$

The corresponding efficiencies for these ideal joints are, from either Eqs. [9] or [10],

$$e_1 = 1 - \frac{0.707}{1.883} = 62.5 \text{ per cent (Single-riveted)}$$

$$e_2 = 1 - \frac{0.707}{5.03} = 85.9 \text{ per cent (Double-riveted)}$$

$$e_3 = 1 - \frac{0.707}{13.4} = 94.7 \text{ per cent (Triple-riveted)}$$

$$e_4 = 1 - \frac{0.707}{35.7} = 98.0 \text{ per cent (Quadruple-riveted)}$$

To design commercial joints from the foregoing, choose, say, d = 0.75 in., p_1 = 2 in., p_2 = 6 in., p_3 = 12 in., p_4 = 36 in., as shown in Fig. 2. This will afford a joint having simple ratios of rivet pitches from row to row. The calculated efficiencies for commercial riveted joints are found in the usual way. A simple calculation will show that R = 37,500 lb. in bearing. Hence no rivets will fail in shear since the shearing resistance is 39,000 lb. Thus, for a quadruple-riveted joint where the unit pitch is 36 in., it is necessary to consider—

a Bearing resistance of all rivets in a 36-in. strip
b Tensile resistance of row 4
c Tensile resistance of row 3 plus bearing resistance of row 4
d Tensile resistance of row 2 plus bearing resistance of rows 3 and 4
e Tensile resistance of row 1 plus bearing resistance of rows 2, 3 and 4.

The values of these resistances are as follows:

a 28 × 37,500 = 1,050,000 lb.
b 35.25 × 60,000 × ½ = 1,057,500 lb.
c (33.75 × 60,000 × ½) + (1 × 37,500) = 1,050,000 lb.
d (31.50 × 60,000 × ½) + (4 × 37,500) = 1,095,000 lb.
e (22.5 × 60,000 × ½) + (10 × 37,500) = 1,050,000 lb.

It will be seen that the liability of rupture will occur under items *a*, *c* or *e*. The resistance of an unperforated strip 36 in. wide is 36 × 60,000 × ½ = 1,080,000 lb. The efficiency is consequently

$$e = \frac{1{,}050{,}000}{1{,}080{,}000} \times 100 = 97.2 \text{ per cent}$$

The thickness of the cover plates is, from Eq. [11], approximately,

$$t_c = \frac{2 \times \tfrac{1}{2} \times 97.2}{200 \times 1.25} = \frac{25}{64} \text{ in.}$$

To make a triple-riveted joint, omit the rivets in row 4 of Fig. 2. A similar set of calculations will show that in a 12-in. strip failure is likely to occur through—

a Bearing resistance of all rivets in a 12-in. strip
b Tensile resistance of row 3
c Tensile resistance of row 2 plus bearing resistance of row 3
d Tensile resistance of row 1 plus bearing resistance of rows 2 and 3.

These resistances have respectively the following values:

a 9 × 37,500 = 337,500 lb.
b 11.25 × 60,000 × ½ = 337,500 lb.
c (10.5 × 60,000 × ½) + (1 × 37,500) = 352,500 lb.
d (7.5 × 60,000 × ½) + (3 × 37,500) = 337,500 lb.

The lowest resistance of the joint is for items *a*, *b* or *d*. The initial strength of the plate is 12 × 60,000 × ½ = 360,000 lb., hence the efficiency is

$$e = \frac{337{,}500}{360{,}000} \times 100 = 93.7 \text{ per cent}$$

The thickness of the cover plates is approximately

$$t_c = \frac{2 \times \tfrac{1}{2} \times 93.7}{200 \times 1.25} = \tfrac{3}{8} \text{ in.}$$

For a double-riveted joint omit rows 3 and 4 of the quadruple joint and the unit strip becomes 6 in. wide. In this case failure may occur through—

a Bearing resistance of all rivets in a 6-in. strip
b Tensile resistance of row 2
c Tensile resistance of row 1 plus bearing resistance of row 2.

Numerically these become

a 4 × 37,500 = 150,000 lb.
b 5.25 × 60,000 × ½ = 157,500 lb.
c (3.75 × 60,000 × ½) + (1 × 37,500) = 150,000 lb.

The strength of the original plate is 6 × 60,000 × ½ = 180,000 lb., hence the efficiency is

$$e = \frac{150{,}000}{180{,}000} \times 100 = 83.3 \text{ per cent}$$

The thickness of the cover plates is about

$$t_c = \frac{2 \times \tfrac{1}{2} \times 83.3}{200 \times 1.25} = \frac{11}{32} \text{ in.}$$

Finally, for a single-riveted joint omit rows 2, 3 and 4. The results for bearing and tension can be put down immediately as

a 1 × 37,500 = 37,500 lb.
b 1.25 × 60,000 × ½ = 37,500 lb.

The original strength of a strip 2 in. wide is $2 \times 60{,}000 \times \frac{1}{2} = 60{,}000$ lb., from which the efficiency is

$$e = \frac{37{,}500}{60{,}000} \times 100 = 62.5 \text{ per cent}$$

The thickness of the cover plates is

$$t_c = \frac{2 \times \frac{1}{2} \times 62.5}{200 \times 1.25} = \frac{1}{4} \text{ in.}$$

The efficiencies just calculated are compared in Table 1 with those obtained by using Eq. [9] or [10].

TABLE 1 IDEAL AND CALCULATED EFFICIENCIES OF DOUBLE-STRAPPED BUTT JOINTS

Type of double-strapped butt joint	Efficiencies, Per Cent	
	Ideal	Calculated
Single-riveted	62.5	62.5
Double-riveted	85.9	83.3
Triple-riveted	94.7	93.7
Quadruple-riveted	98.0	97.2

There are two things worthy of note in the method that has been presented. One is, that the design of a quadruple-riveted joint presupposes the design of the triple-, double- and single-riveted joints. Thus there is symmetry existing in all of these joints and manufacturers will find it easy to standardize them should it be found advisable to do so. The other follows from a discussion of the equations of bearing and tension on the plate. Equating these,

$$dtf_c' = (p_1 - d)\, tf_t$$

from which

$$p_1 f_t = df_c' + df_t$$

so that the expression for the pitch becomes

$$p_1 = d\left(1 + \frac{f_c'}{f_t}\right)$$

Since f_c' and f_t are properties of the materials used and therefore constants, the last equation might be written in the form

$$\frac{d}{p_1} = \text{constant}$$

This ratio appears in the equation for efficiency, Eq. [10], and due to the linear relation between p_1 and d the same efficiency might be obtained with an infinite number of values of d. For instance, if d is doubled then p_1 must be doubled, and so on. There is a certain minimum value that d might have in any joint and that value has been found in Eq. [2], where a smaller value will cause the rivet to fail by shear. Hence no ambiguity arises in this case. Commercial considerations require the smallest rivet in general, while for very thin plates where the rivet sizes are very small it is desirable to know that, even with these, good efficiencies may be obtained by increasing the pitch in the same ratio as the rivet diameter.

In connection with assumptions b and c at the beginning of the paper, the supposition is made that the shear and bearing are uniformly distributed among the rivets of a given joint. To prevent too serious a deviation from this premise, the cover plates might be designed in the following way: Let it be assumed at the start that each rivet is properly driven, then, in an ideal case, the same metal-to-metal contact exists among all the rivets. For this condition to prevail after loading requires that the same stress exist in the cover plate as exists in the connected plate. Under these conditions the deformation under load will be the same for both cover plates and connected plate. In commercial joints, departures from the ideal case arise which may be somewhat obviated by scalloping the cover plates for triple- and quadruple-riveted joints, as shown in Fig. 3. This will decrease the rigidity of the cover plate and to some extent prevent the rivets of the outer rows from taking an undue share of the whole load.

EXTINGUISHING AND PREVENTING OIL AND GAS FIRES

For the past three years the Bureau of Mines has been conducting investigations to determine the nature and the specific causes of oil and gas fires, with a view to suggesting means whereby they may be successfully combated, and even eliminated, if possible. In a bulletin recently issued by the Bureau, C. P. Bowie points out what has been done by operators in the past, and describes various fire-prevention methods and fire-fighting apparatus which are being used or adopted by many of the larger oil companies. These methods and apparatus, it is stated, if universally employed by operators, will largely decrease the present enormous annual losses, of which some idea may be found by quoting from the statistics of the Bureau that during the period of ten years from January 1, 1908, to January 1, 1918, approximately 12,850,000 bbl. of oil and 5,024,506,000 cu. ft. of gas were destroyed by fire in the United States.

Oil and gas fires are caused principally by lighting and frictional electricity, and to a lesser extent by carelessness. Static

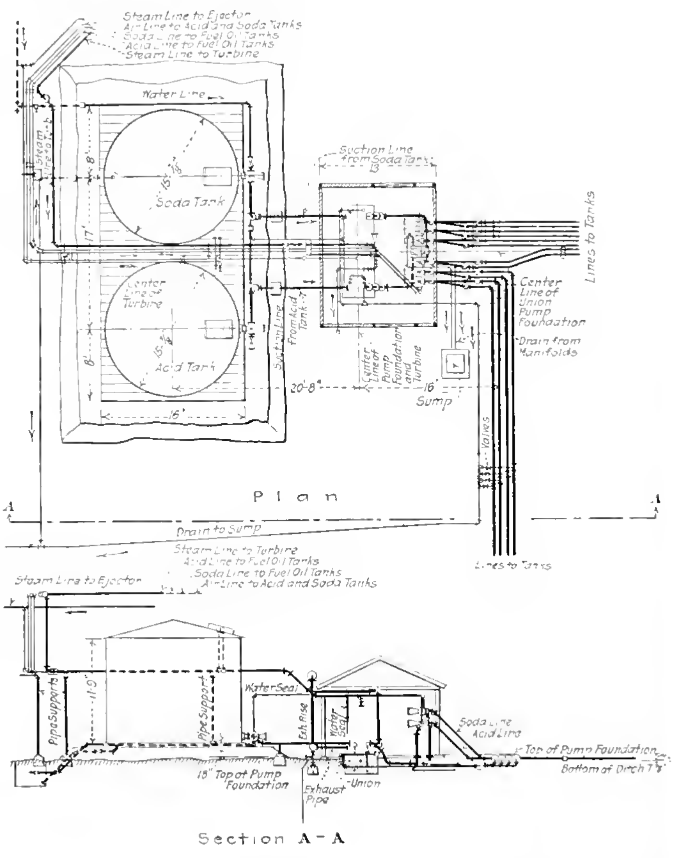

FIG. 1 GENERAL ARRANGEMENT OF SUCTION AND DISCHARGE PIPING AT PUMPS, FROTHY-MIXTURE SYSTEM

electricity accounts for the origin of a number of seemingly mysterious fires. An unpublished report of the chemist for the Massachusetts District Police to the chief of the Boston Fire Department mentions the following instances:

A chauffeur desiring to fill a large limousine, which was standing on the cement floor of a garage, took an ordinary 50-gal. can having a wooden handle on the bail, and hung it by this wooden handle on the hook of a self-measuring gasoline pump connected with an underground tank in the yard outside. He had drawn about a gallon when he heard a snapping noise, and the can was in flames. . . .

At another garage an employee filled a 5-gal. can with gasoline from a pump and took it to the running board of a car. He had an ordinary metal funnel across which was stretched a piece of chamois skin, and, to make the funnel sit upright on the car tank, he had attached a thin piece of wood, with a hole in it, for the funnel spout. He stood on the running board and held the pouring can quite near the edge of the funnel, but not touching it, when he saw a spark jump from the funnel to the can. It ignited the gasoline.

The explanation of the first fire is that the friction of the flow-

ing gasoline against the bottom and sides of the can generated electricity that charged the can: when the potential of the charge became too great, the discharge took place between the metal of the bail and the pump. The second case cited presented practically the same phenomenon. The funnel was insulated from the tank by the board at its base, and the funnel became charged with the electricity developed by friction of the gasoline flowing through the chamois skin.

Fires in oil tanks are successfully extinguished by the so-called frothy-mixture system. Essentially this system provides for bringing together two chemical solutions and for feeding into the top of burning oil tanks the thick, tenacious foam resulting from their combination, thereby excluding air and extinguishing the flame. The apparatus required in practice comprises two tanks—one for each chemical solution—a suitable pump, pipe lines to carry the solution to the oil tanks or reservoirs, mixing chambers where the chemicals can combine, and a means for properly distributing the foam.

The solutions for producing the foam may be any two compounds that on coming together form an abundance of relatively tough bubbles inflated with a non-inflammable gas. The chemicals must be fairly cheap; also they must not deposit any appreciable amount of sediment after having been in solution for a considerable time. The proportion of froth to solution should be about 6 or 8 to 1, that is, combining 50 cc. of each solution should produce 600 to 800 cc. of foam.

The installation put in by the Associated Pipe Line Co. at Coalinga, Cal., and shown in Fig. 1, was designed to protect four 55,000-bbl. oil tanks each 114 ft. 6 in. in diameter, one 30,000-bbl. tank 86 ft. in diameter, and two fuel-oil tanks each about 8 ft. in diameter. The solutions used at this station have the following composition:

Solution A	Parts by weight	Solution B	Parts by weight
Water	100	Water	100
Aluminum sulphate (crystal)	10	Ground glue	$1\frac{1}{4}$
Sulphuric acid, 66 deg. B.	$\frac{1}{2}$	Glucose	$\frac{1}{2}$
		Sodium bicarbonate	$7\frac{1}{2}$
		Arsenious oxide	1–52

Other formulæ are:

FORMULA 1

Solution A	Parts by weight	Solution B	Parts by weight
Water	100	Water	100
Aluminum sulphate (crystal)	14	Sodium bicarbonate	$9\frac{1}{4}$
Extract of licorice (powdered)	3		

FORMULA 2

Water	100	Water	100
Aluminum sulphate (crystal)	12	Sodium bicarbonate	10
Acetic acid	$\frac{1}{2}$	Ground glue	1
Ground glue	1	Glucose	$\frac{1}{4}$
Glucose	$\frac{1}{4}$		

The capacities of the solution tanks depend on the number of square feet of oil surface to be covered. On an estimate that 1 gal. of mixture ($\frac{1}{2}$ gal. of each solution) will produce 7 gal., or 1617 cu. in. of foam, to cover the oil in a 55,000-bbl. tank with 6 in. of foam would require about 2800 gal. of each solution. This quantity, of course, should be increased by using a reasonable safety factor.

Fires at gas wells, except at wells producing large volumes of gas, are, as a rule, not particularly difficult to overcome if the gas can be confined in one stream, because if the flow can be cut off for an instant the flame will be extinguished. When the gas flow has been confined in one stream the flame, unless it is very small, will always be some distance above the casing. The greater the pressure of the gas the longer this column of unburned gas will be. If enough steam or water can be directed against this part of the gas column to interrupt the stream of ascending gases momentarily, even the largest fire will be put out. In putting out gas-well fires with steam, the usual practice is to set up portable field boilers in the vicinity and surround the burning well with steam pipes terminated in goosenecks, which throw a fan-shaped spray of steam against the gas column. Steam is turned on from all boilers simultaneously; if the volume is sufficient, a blanket or cloud of steam will be formed and momentarily interrupt the gas stream just above the head of the casing, and the fire will be extinguished.

H. O. Ballard, of the Empire Gas & Fuel Co., has adapted the snuffer principle to a portable extinguisher. The device consists of a hood mounted on wheels and terminating in a valve to which is attached a piece of 14-in. pipe about 20 ft. long. The pipe can be extended to any desired length by screwing on more joints. On either side of the hood, midway of its height, is a short piece of 10-in. pipe also containing a valve. The hood is taken to the side of the burning well and upended over the fire, with the large valve opened and the two small valves closed. When the hood has reached its vertical position, the lower valves are opened and the large one closed, thereby cutting off the flame. If the flow of gas is so strong that the discharge from the 10-in. pipes may reach the top of the stack and ignite before the large valve can be closed, the 10-in. pipes are extended to a safe distance from the well before the valves are manipulated.

Oil-well fires are often much more difficult to overcome than gas-well fires, because the well may be producing in such large quantities that the oil is not all consumed in one tapering flame as with gas. Also, the burning oil soon heats the ground around the well so hot that, no matter how often the fire may be extinguished, it will immediately reignite. Consequently, no definite rules can be given for combating fire at oil wells, as each burning well presents a problem of its own. Special precautions should be taken against fires in oil wells, as the process of extinguishing them is always laborious and difficult. The practice of having a fire inside of the derrick has been the cause of many fires about drilling wells. Gas fires about oil wells being drilled are, in most instances, wholly inexcusable, as permitting gas to escape unchecked from the well is a wasteful and, as a rule, unnecessary procedure. All bearings about the machinery, especially the bull-wheel, calf-wheel and sheave-wheel bearings, should be kept thoroughly oiled. Static electricity generated by the band-wheel belt or other moving parts of the machinery has often caused fires; danger from this source can be prevented by grounding all machinery parts and providing belts with properly constructed copper brushes attached to a grounded pipe. Numerous other precautionary measures have been devised for cases where there is danger of the oil coming in contact with a flame or a spark.

The recent developments of wireless telegraphy have required the use of more powerful Hertzian waves than had been sent out by any station up to the time of the war. There are present, therefore, in the ether permeating and surrounding the atmosphere, numerous trains of waves traveling in all directions. It is altogether possible that one of these sets or a set resulting from a combination of several of them should come in contact with a number of conducting bodies so arranged in a casual manner as to form a Hertzian resonator of the required inductance, capacity and resistance to respond to the passing train. There would then be an ether wave excited in the system, a spark would be produced and a fire probably caused as the result of the passage of the wave.

Mr. George A. Le Roy has presented to the Académie des Sciences a note on the possibilities of a fire being produced in this manner. He conducted a laboratory investigation by means of an apparatus which he terms "inflammatory-resonator." It consists of a globular glass flask provided with four openings, two lateral, one at the top and one at the bottom. Through the lateral openings two electrodes are introduced and kept at the desired distance apart by an adjusting mechanism; they constitute the terminals of a Hertzian resonator. The bottom opening permits placing under the electrodes a plate which carries the inflammable substances; there is also at the bottom a connection for exhausting air with a pump, or introducing gases into the globe. Through the top are located the required measuring instruments.

Hertzian waves of relatively low intensity, generated by means of an ordinary Ruhmkorff coil, were sent through the instrument.

Mr. Le Roy asserts that iron electrodes facilitated the inflammation of cotton, amadou, paper, tow, etc. He, therefore, concludes that a condition may be produced in such a case as the piling of a number of cotton bales, when by the breaking of one of the iron bracings an open resonator is virtually formed.

THE HEAVY-OIL ENGINE

In line with the prevailing tendency of engineers of related branches to forgather and discuss their mutual problems, the New York Section of The American Society of Mechanical Engineers and the Metropolitan Section of the Society of Automotive Engineers held a well-attended joint meeting at the Automobile Club of America, on the evening of April 9, at which various topics connected with the development of the heavy-oil engine were dealt with in brief addresses. Dr. Charles E. Lucke, Dean of the School of Mechanical Engineering, Columbia University, and late Director of the U. S. Naval Gas Engine School, presided over the meeting.

J. H. Smootz, of the U. S. Bureau of Mines, Petroleum Division, spoke on the methods employed in refining petroleum, and in obtaining lighter oils from the heavier fractions by the cracking process, as well as on the general properties of the various products. From the 13-odd billion gallons of petroleum annually produced in the United States, 1.8 billion gallons of kerosene were obtained and twice as much gasoline; the remainder being gas oil, distillate and light and heavy residuals, which latter were convertible into distillate. Costs of treatment were low and selling prices of the various products were purely dependent on the demand. Kerosene was relatively scarce and in his opinion not a fuel that would affect the situation to any considerable degree.

Dr. Lucke, in discussing the adaptation of the engine to the fuel, called attention to the necessity of heated vaporizing appliances when heavy gas oils and kerosene were used as engine fuels, and to the advantages of late injection. The heaviest, unvaporizible oils if injected in a fine enough spray, well scattered and homogeneously mixed with air, would explode as if gaseous. There was no question but that the engineers could adapt the engine to the fuel, and the chemists would see to it that cheap fuels were supplied. The important problem ahead was to adapt the engine to its various uses, and the interchange of ideas at meetings like the one in session would contribute largely to bringing this about.

J. M. Hunt, of the Dayton Engineering Laboratories Company, told of the possibilities of adapting automobile engines to fuels heavier than motor gasoline, and of experimental work he had carried on in this direction, particularly with kerosene. One car had been run 14 months on this fuel, covering 12,000 miles and without engine trouble developing. Preheated air was used and the mixture heated to 220 deg. and then compressed. Another way to avoid the difficulties of starting with a cold engine was to use two fuels, one highly volatile, to warm up the engine, but this involved needle-valve troubles. In regard to the kerosene "knock," experiments at Dayton had shown this to be due, not to preignition, as many supposed, but to abnormal pressures—three to five times the normal explosion pressure—developed probably through the detonation of some product of combustion. The introduction of water or cool exhaust gas had been suggested as remedies for knocking, but manifestly this was not a final solution. The problem ahead was to design engines to use fuel and gas oils, for the limits of the gasoline and kerosene supply were already in sight.

A short paper by A. H. Goldingham, of the De La Vergne Machine Co., on the heated-metal type of heavy-oil engine, was read in the author's absence by the chairman. The desiderata in an engine of this type, it was stated, were reliability, first cost and economy. As to reliability, engines would run six months continuously, using any fuel, and with an odorless and practically invisible exhaust. This had been accomplished by thorough atomization and aeration of the oil sprayed in under 4000 to 5000 lb. pressure; improved construction of vaporizing chamber; and by the use of forced-feed lubrication, an automatic air starting valve and an improved vaporizer heating lamp or electric heating coil. Four-cycle engines up to 400 hp. running at 900 ft. per min. piston speed cost today $120 per hp. as against $55 in 1913, and weighed 425 lb. per b.hp. They operated regularly on 0.4 lb. fuel per b.hp., and at 6 cents per gal., $1000 would buy the fuel for a 100-hp. engine for a year.

Mr. Hansen, of the Skandia Pacific Oil Engine Co., told of his experience on the Pacific Coast in connection with the installation of Werkspoor engines in the wooden ships built by the Emergency Fleet Corporation. These ships had been constructed of green timber, with the result that there were many bedplate breakages due to shrinkage and warping of foundations, but charged nevertheless against the engines. Large hot-bulb engines required care, but it had been impossible to train properly the large number of engineers needed in the time available.

T. O. Lisle, editor of *Motorship,* said that the new type of motorship developed by the United States during the war—the wooden auxiliary—had been unsuccessful, as in addition to being constructed of green timber, they had been equipped with insufficient sail power so that the auxiliary engines were forced to the limit, and it had furthermore been necessary to operate them by untrained engineers. A 5000-ton boat had been provided with an engine of only 700 hp. In his opinion steel hulls should be adopted for such vessels and the powering raised, to range from 500 hp. for a 2000-ton boat up to 1100 hp. for a 5000-ton vessel. Stationary Diesel engines had been so developed that six-cylinder 4000-hp. engines were now being built and 5000 hp. was possible. A 20,000-ton 16-knot boat equipped with large power units would require space for but 14 tons of oil per 24 hours, and but 20 men in the engine room. He believed it would have been much better if the Emergency Fleet had consisted entirely of motorships. Eighty-six concerns were now building Diesel engines—50 on a large scale, and 150 concerns semi-Diesels. As to reliability in service, he would cite the *Zeelandia,* a vessel of 7500 tons built in 1912 and with engines of 2750 i.hp., which had sailed a total of 327,000 nautical miles at an average speed of 10.4 knots and had consumed 11,667 tons of fuel oil in her 31,600 hours at sea.

In the brief discussion which followed, referring to the matter of reliability, J. H. Norris stated he had been told that a motorship had never had to be towed into port.

H. C. Verhey, of the engineering staff of the Emergency Fleet Corporation, who had had twelve years' experience with Diesel engines and was familiar with European conditions, said that the materials of construction available in the United States were of superior quality and it was not necessary now to go abroad for designs, engineering talent or workmanship. Moreover, facilities here were better and our castings could not be surpassed in excellence by anything in Europe.

Harte Cooke, of the McIntosh & Seymour Corp., in discussing Diesels for stationary use, said that with the lighter fuels, if the fuel valve was too hot, the oil would crack and clog the burner plates. Careful cooling of the fuel valve would do away with this, but it was better to use a heavier grade of fuel. All oil fuels available could be successfully burned, even those carrying sulphur. With the latter, however, it was best to run a short time with sulphur-free oil before shutting down. This would carry the SO_2 out of the system and prevent the piping from being attacked.

Preceding the meeting, dinner was served in the grill room of the Automobile Club. The arrangements were in the hands of W. W. Macon, Chairman of the A.S.M.E. New York Section, and A. M. Wolf, Secretary of the S.A.E. Metropolitan Section. Before the speakers of the evening were introduced, Mr. Macon stated that the gathering was but one of a series of special meetings planned to secure closer coöperation among the various local organizations of engineers.

Raw Material, heretofore issued as *The Metal Record and Electroplater,* made its initial appearance under the new name with the March 1919 issue. This journal has recently been acquired by the Gage Publishing Company, well known as the publishers of the *Electrical Record* and *Electrical Export,* and it is planned to considerably widen the field of *Raw Material.* The new editor in chief is R. L. Herrick, formerly western editor of *Mines and Minerals,* later of the staff of the *Engineering and Mining Journal,* and until recently assistant publicity manager of the Ingersoll-Rand Company, of New York.

Electric Welding as Applied to Ship Construction

By H. Jasper Cox,[1] New York, N. Y.

Few subjects offer as great inducements for experimental research as that of the application of electric welding to shipbuilding, and it is doubtful whether in the whole range of applied science intimately concerned with practical developments in both industries greater potentiality is open than under the various headings in which the subject of electric welding naturally divides itself.

Although electric welding, and especially arc welding, has been used for a long time to great economical advantage in ship-repair work and marine engineering, it has been but little understood, and it is not overstating the case to say that it is only within recent months that any serious attempt has been made to analyze the elements of the art and determine the underlying scientific principles involved.

The chief investigator in this field was the General Engineering Committee of the Council of National Defense, which has made a very careful study of the application of spot welding to ship construction. In January 1919, however, this committee was dissolved and the Electric Welding Committee of the United States Shipping Board, Emergency Fleet Corporation, was appointed to investigate the whole field of electric welding and to advise the Emergency Fleet Corporation as to how the shipbuilding program might be speeded up and work economized by a wider adoption of the process.

The committee is composed of shipbuilders, electrical engineers, many prominent physicists and metallurgists, and of representatives of the Emergency Fleet Corporation, Classification Societies and Bureau of Standards, with Prof. Comfort A. Adams, of the Massachusetts Institute of Technology and President of the American Institute of Electrical Engineers, as Chairman.[2]

Much useful work has already been accomplished by the committee, data collected, investigations and research work carried out and important facts established. In the meantime similar investigations and research work were being conducted abroad, particularly in Great Britain, where an exhaustive series of practical experiments has recently been completed by the Technical Committee of Lloyd's Register of Shipping.

The results of these investigations have been not only encouraging, but have led to the conclusion that under certain prescribed conditions an electrically welded joint may with reasonable safety be applied to the main structure of a vessel.

Methods of Welding

The methods of electric welding applicable to ship construction can be considered under two main headings, resistance welding and arc welding.

Resistance Welding. As the term implies, it is the resistance offered to the flow of electric current through the material and contact surfaces to be united which causes the metal in the path of the current to heat up to the necessary temperature. Welding is then accomplished by the application of pressure. There are two distinct kinds of resistance welding—spot welding and butt welding.

Spot welding has been extensively used for jointures of thin metal such as ventilators, lifeboats and railway cars, and with considerable success, but it is only recently that its application to sheet plates and bars of the thickness required in ship construction has been investigated.

The two or more pieces to be welded are overlapped or superposed to form the joint and clamped between two copper electrodes; then current is passed through and pressure applied. In order to insure a successful weld the pressure should be sufficient to cause the metal to "flow" at the weld and to extrude all oxides, slag, etc., which may form. The pressure is maintained for a short time after the current is cut off, and the operation is then repeated at the next spot. Small buttons or disks of metal are sometimes placed under one or both of the electrodes, and when of proper thickness are completely submerged in the plate metal during the operation of forming the weld.

Intensive research work is now being conducted along these lines by the General Electric Company, who have built a heavy spot-welding machine, shown in Fig. 1, with a capacity of 100,000 amperes at 20 volts and a hydraulic pressure of 36 tons at the electrodes. A careful series of experiments is being carried out with this machine, using plates of from ¼ in. to 3 in. in total thickness, and it has already been demonstrated that satisfactory spot welds can be made within this range. It has also been found that an appreciable range is permissible in the variables of current, pressure and time without seriously impairing the efficiency of the weld for a given thickness of material.

Where considerable tensile pull is anticipated in an overlap joint, it is considered desirable to have a double row of spots to prevent the tendency to bend and tear out the spots in the same manner as the countersunk heads of rivets are sometimes torn through the holes in a single-riveted overlap.

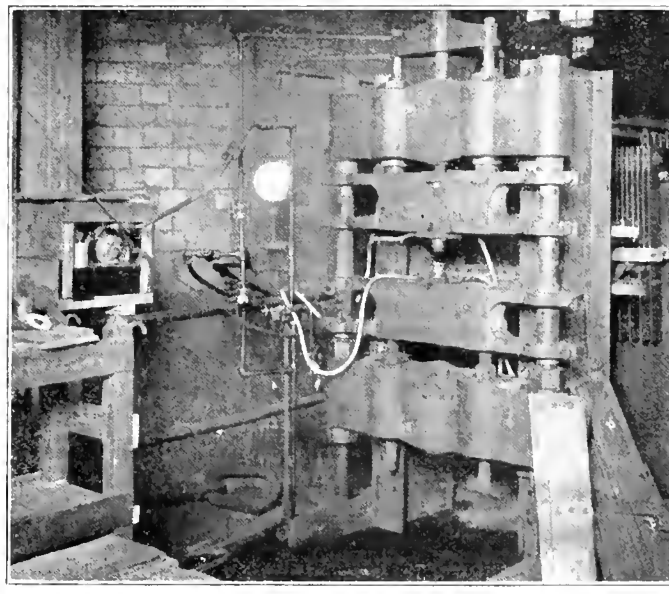

Fig. 1 Spot-Welding Machine made by General Electric Co. Current Capacity, 100,000 amperes; Pressure, 36 tons

Figs. 2 and 3 show some joints made during these experiments, which at the time of writing are still proceeding, and will no doubt shortly yield definite and comprehensive data. Although this method of welding has not yet reached the stage of development which might warrant its practical application to ship construction, it offers every prospect of doing so within the very near future. Obvious developments with this system are multiple spot and continuous or seam welding, both of which will tend toward great saving in time. In general, spot welding is much more rapid than arc welding and requires less labor, but more power and a much heavier and more expensive machine.

Butt welding is especially applicable to bars of uniform section and will probably have a broad future in jointing the reinforcements in ferro-concrete construction. The bars to be welded are brought together, end on, clamped and a low-pressure current passed through until a welding heat is obtained. Then end pressure is applied until the metal at the joint shows signs of squeezing

Abstract of paper presented at the Annual Meeting of the Society of Naval Architects and Marine Engineers, Philadelphia, on November 14 and 15, 1918.

[1] Lloyd's Register of Shipping.

[2] Representatives of the gas-welding industry have recently been added to this committee, and the title changed to The Welding Committee.

out. A machine for this type of welding has been ordered by the Emergency Fleet Corporation and will be tried out during the construction of a 3500-ton (dead weight) reinforced-concrete steamer now being built by the Fougner Concrete Shipbuilding Company.

Arc Welding. In this method of welding the electrode and the material to be welded are connected in a simple electric circuit and an arc is struck by bringing the electrode in contact with the work at the point where the weld is to be made, then withdrawing it slightly to obtain the desired length of arc. The two principal methods of applying this process are by means of the carbon arc and the metallic arc.

In the former a carbon electrode is used and the heat from the arc produced brings the metal to a fusion heat. When welding with the carbon arc additional metal is introduced into the arc and fused into and with the parent metal at the joint. Its main field of application, however, is in rough cutting in foundries and steel mills and for the repair or building-up of imperfect castings. It has not been advocated for use in ship construction generally and there are a number of reasons which make it doubtful whether it ever will be.

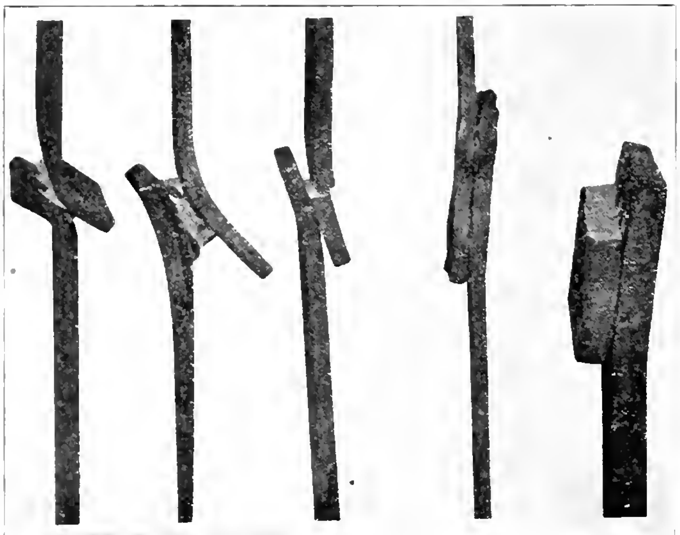

Fig. 2 Electrically Welded Steel Plates After Being Tested in Tension

In metallic-arc welding a metal electrode is used of approximately similar material to that being welded, the electrode itself is fused by the arc, and molten particles are carried over the arc into the fused portion of the parent metal, thus gradually building up the joint.

The actual operation, however, is not quite so simple as this sounds, as there are a large number of variables, any one or any combination of which may affect the efficiency of the result to a greater or less extent. These variables may be enumerated as follows:

1 The type of electrode, i.e., bare metal or covered
2 Chemical composition of the electrode
3 Chemical composition of metal being welded
4 Size of electrode
5 Kind of current, i.e., alternating or direct
6 Amperage and voltage
7 Skill of the operator
8 Method of preparing and building up the joint.

Training of Welders

Of these the skill of the operator is still the most vital factor, and it is probably because of this that arc welding is known as an art rather than a science. A skilled and properly trained welder knows instantly whether or not he is making a good weld. He can tell this by the smoothness of the flow of metal, the uniformity of the sound and light of the arc, and by the lack of "spattering" or deposition of "beads." When his arc is not welding he should immediately cease work, remedy the cause, whether it be unsuitable current control or faulty electrode, and, before proceeding again, should chip out the bad work and especially where the arc was broken. It will be seen, therefore, that the welder should possess some knowledge of the elements of electricity, how it is generated, conducted and controlled, the melting point of the metals employed, and the properties of the particular electrode in use. In ship work he should understand the correct methods of preparing the various joints and their relative importance, together with the best methods of building them up. It is therefore a *sine qua non* of welding the main structure of a vessel that only skilled operators be used. Recognizing this, the Emergency Fleet Corporation has established a separate training and education department for electric welding and has opened schools for the training of operators and instructors in New York, Newport News, and the Great Lakes district.

Lloyd's Experiments on Electrically Welded Joints

When the development of electric arc welding had reached a stage at which its application to the main structure of a vessel, with all the attendant possibilities, appeared a feasible proposition, the Technical Committee of Lloyd's Register of Shipping, in accord with its traditions, immediately embarked upon an exhaustive investigation in order to determine at first hand the suitability of electrically welded joints for such work. A series of experimental tests was accordingly devised and carried out under the direction of the society's technical staff in England, extending over a period of many months.

It is commonly accepted that the tests imposed on manufactured material do not in any way represent the strains which may be experienced in practice. Such tests are rather based on simple means for determining the average reliability of the material.

Fig. 3 Samples of Electric Spot Welding

Thus, also, in this case no one particular test is likely to determine whether the welding process under trial is sufficient for the work it is likely to have to do. It is therefore necessary to approach the problem rather on the basis of circumstantial evidence and to decide from a number of different types of experiments whether, on the whole, the performance is satisfactory.

The investigations were undertaken to determine the possibilities of the application of electric arc welding to shipbuilding, and, as it was desired to obtain as good a knowledge as possible of the physical properties of the combination of rolled and welded material, only highly skilled operators were employed. It must therefore be realized that the results of the experiments which have been made represent skilled practice, and that in general such performance can only be equaled with good workmanship and efficient supervision. The "Quasi Arc" process of electric arc welding was used throughout the experiments.

NATURE AND DESCRIPTION OF EXPERIMENTS

The general scope of the experiments included:

1 Determination of modulus of elasticity and approximate elastic limit

2 Determination of ultimate strength and ultimate elongation

3 Application of alternating stresses with (*a*) rotating specimens, (*b*) stationary test pieces

4 Minor tests, such as (*a*) cold bending of welds, (*b*) impact tests of welded specimens

5 Chemical and microscopic analysis

6 Strength of welds.

Tests were carried out on specimens as large as possible, particularly in respect to the static determinations of elasticity, ultimate strength and elongation, some of the test specimens being designed for a total load of just under 300 tons. The advantage of these large specimens was that the effect of workmanship was better averaged and the results were more comparable to the actual work likely to be met with in ship construction.

Fig. 4 illustrates the method adopted to measure the modulus of elasticity by means of a strainmeter designed by Dr. James Montgomerie, principal surveyor for Lloyd's Register in Scotland. The illustration shows the holders which were specially designed with a view to securing, as far as practicable, an even pull across the breadth of the plate. Readings were taken in way of the weld and at various points on the plate itself, both adjacent to and well clear of the weld, and the points at which these observations were taken are clearly shown in Fig. 5.

Typical results, illustrating the extensions as measured along the line *C*, are shown in Fig. 6, from which it would appear that the extensions in way of the weld do not show any marked difference from those at various points in the plain plate, the lines showing extensions in way of the weld lying among the others without disclosing any distinctive features. Measurements were also taken with the strainmeter set at right angles to the line of pull, the readings in this case, of course, representing contractions.

With a view to confirming this result a set of specimens of smaller size was prepared and tested. The curves obtained exhibit the same general characteristics as those of the large specimen and would appear to justify the inference that there is very little difference between the modulus of elasticity of the welded samples and that of the plain plate.

With alternating stresses the specimens were relatively of small size. For the rotating test pieces, circular rods, machined from a welded plate, were used, the diameters selected being 1 in. and ¾ in. These bars, about 3 ft. in length, were attached to a lathe headstock, and a pure bending moment in one plane was applied by means of two ball races to which known weights were attached. The material of the bar was thus exposed alternately to maximum tension and to equal maximum compression once in each revolution. The machine was run at about 1060 r.p.m.

Bars of identical material were tried in pairs, one specimen welded and the other unwelded, and the number of revolutions before the specimens parted was observed for various ranges of stresses varying from ± 15 tons to ± 6 tons per sq. in. Fig. 7 clearly shows the stresses at which the welded and unwelded bars will withstand a very large number of repetitions of stress.

In the second series of alternating-stress experiments flat plates were used of three thicknesses, viz., ¼ in., ⅜ in. and ½ in. These specimens were tried in groups of four, each group consisting of one plain, one butt-welded, one lap-welded and one lap-riveted plate. The specimens, which were about 14 in. long and 5 in. broad, were clamped along the short edges, so that the distance between the fixed lines was 12 in. Each plate was also clamped, near the middle, to the end of a pillar, which by means of a crank arm was caused to oscillate and to bend the specimen equally up and down by adjustable amounts (the maximum total movement in any of the experiments tried was 5/16 in). The machine was run at various revolutions (not exceeding 9 per min.), and the number of repetitions at which the specimen parted was observed. Typical results obtained are illustrated in Fig. 8, in which the ordinates represent total displacement from normal position, i. e., 2/16 in. means 1/16 in. up and 1/16 in. down.

The experiments on bending consisted of doubling the welded plate over a circular bar of diameter equal to three times the plate thickness and comparing the results with those of the plate of the same material, but unwelded. Fig. 9 shows the results obtained from the bending tests, and it will be noticed that the angle at which fracture occurs decreases rapidly with increased thickness of plate.

In the impact tests heavy weights were dropped from various heights on to the welded portion of a plate 5 ft. long and 2 ft. 6 in. in breadth, the weld being across the plate, parallel to the shorter edge. The deflections were noted and the condition of the weld was examined after each blow.

Other tests to determine the relative value of welding and calking under tension and the relative bearing value of a riveted or welded lug attachment are shown in Figs. 10 and 11. In the former, two plates are attached at right angles by an angle lug with closely spaced rivets and the angle calked on both edges, similar to the boundary angles of a watertight or oiltight bulkhead. The object of the test was primarily to ascertain at what stress the "tightness" of the attachment was destroyed as compared with that of the welded attachment. The results indicated

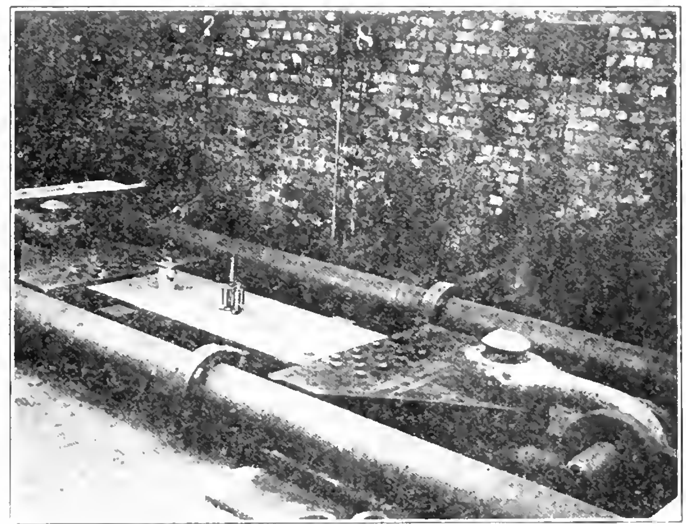

FIG. 4 LLOYD'S METHOD OF MEASURING MODULUS OF ELASTICITY

are very striking. The test shown in Fig. 11, in which a direct shearing force was applied to the lug attachment, indicates the relative values as between riveting and welding a lug attachment for such work as bracket connections. It will be observed that the welded lug is notched out at its mid-length and the welding applied only at the ends and in way of the notch.

The chemical and micrographical examination followed the ordinary practice.

SUMMARY OF EXPERIMENTAL RESULTS

1 *Modulus of Elasticity and Approximate Elastic Limit*

a In a welded plate the extensions in the region of the weld are sensibly the same as for more distant portions of the unwelded plate.

b With small welded specimens containing an appreciable proportion of welded material in the cross-sectional area, the relation between extension and stress is practically the same, up to the elastic limit, as for similar unwelded material.

c The elastic limit (or the limiting stress beyond which extension is not approximately directly proportional to stress) appears to be slightly higher in welded than in unwelded material.

d The modulus of elasticity of a small test piece, entirely composed of material of the weld, was about 11,700 tons per sq. in. as compared with about 13,500 tons for mild steel and about 12,500 tons for wrought iron.

2 *Ultimate Strength and Ultimate Elongation*

a The ultimate strength of welded material with small specimens was over 100 per cent of the strength of the unwelded steel

plate for thicknesses of ½ in., and averaged 90 per cent for plates of ¾ in. and 1 in. in thickness.

b Up to the point of fracture the extensions of the welded specimens are not sensibly different from those of similar unwelded material.

c At stresses greater than the elastic limit, the welded material is less ductile than mild steel, and the ultimate elongation of a welded specimen when measured on a length of 8 in. only averages about 10 per cent as compared with 25 to 30 per cent for mild steel.

3 *Alternating Stresses*

a Rotating Specimens (round bar). Unwelded turned bars will withstand a very large number of repetitions of stress (exceeding, say 5 millions) when the range of stress is not greater than from 10½ tons per sq. in. tension to 10½ tons per sq. in. compression. Welded bars similarly tested will fail at about the same number of repetitions when the range of stress exceeds 6½ tons per sq. in.

b Stationary Test Pieces (flat plate). Butt-welded specimens will withstand about 70 per cent of the number of repetitions

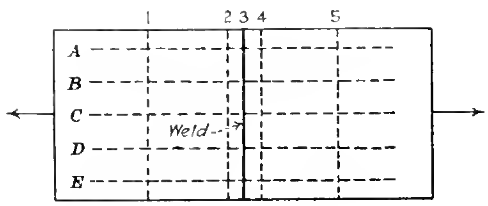

FIG. 5 POSITION OF READINGS, LLOYD'S METHOD

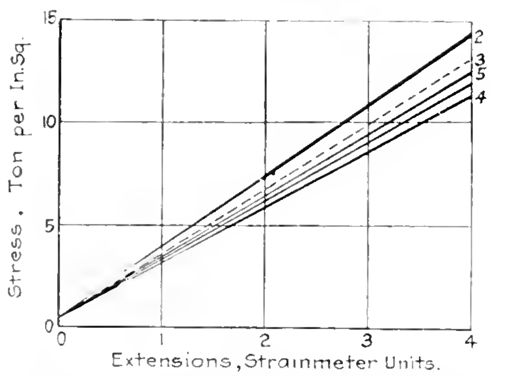

FIG. 6 EXTENSIONS IN DIRECTION OF PULL, READING ALONG LINE C OF FIG. 5

which can be borne by an unwelded plate. Lap-welded plates can endure over 60 per cent of the number of repetitions necessary to fracture a lap riveted specimen.

4 *Minor Tests*

a Welded specimens are not capable of being bent (without fracture) over the prescribed radius to more than about 80 deg. with ¼-in. plate, reducing to some 20 deg. where the thickness is 1 in. Unwelded material under the same conditions can be bent through 180 deg.

b Welded plates can withstand impact with a considerable degree of success; a ½-in. plate of dimensions already quoted sustained two successive blows of 4 cwt. dropped through 12 ft., giving a deflection of 12 in. on a length of about 4 ft. 6 in. without any signs of fracture in the weld.

5 *Chemical and Microscopic Analysis*

a Chemical Analysis. The electrode was practically identical with mild steel, but there was a greater percentage of silicon. The material of the weld after deposition was ascertained to be practically pure iron, the various other contents being carbon, 0.03; silicon, 0.02; phosphorus, 0.02; and manganese, 0.04 per cent, respectively.

b Microscopic Examination. The material of the weld is practically pure iron. The local effect of heat does not appear to largely affect the surrounding material, the structure not being much disturbed at about 1/16 in. from the edge of the weld. The amount of disturbance is still less in thin plates. The weld bears little evidence, if any, of the occurrence of oxidation. With welds made as for these experiments, i. e., with flat horizontal welding, a sound junction is obtained between the plate and the welding material.

6 *Strength of Welds*

a Butt welds have a tensile strength varying from 90 to 95 per cent of the tensile strength of the unwelded plate.

b Lap welds with full fillets on both edges have an ultimate strength in tension varying from 70 to 80 per cent of that of the

TABLE 1 COMPARATIVE STRENGTH OF RIVETS AND WELDED JOINTS

Thickness, in.	Diameter of rivet, in.	Breaking stress unperforated plate, lb. per sq. in.	Strength of plain plate, lb. per sq. in.	Percentage strength o joint
TRIPLE-RIVETED LAP JOINTS				
0.49	⅞	42,400	61,400	69.0
0.53	¾	38,300	54,700	62.5
LAP WELD—FULL FILLET—BOTH EDGES				
0.514	10.02[1]	45,300	63,600	71.0
0.730	8.76[1]	40,330	59,600	68.0
BUTT WELD—NOT STRAPPED				
0.505	10.66[1]	61,000	63,600	96.0
0.760	9.88[1]	54,680	59,600	91.5

[1]Total sectional area, square inches.

unwelded material. With a full fillet on one edge and a single run of weld on the other edge the results are very little inferior to those where a full fillet is provided for both edges.

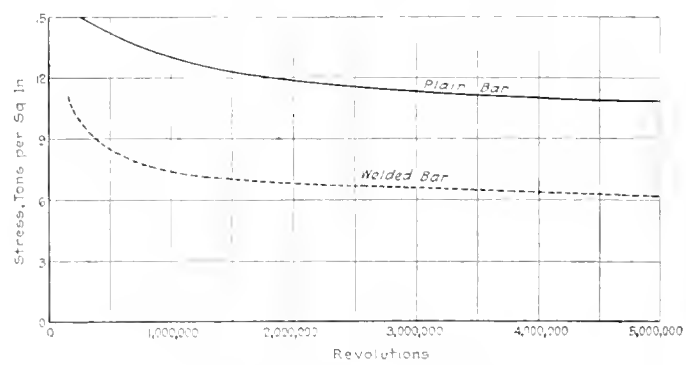

FIG. 7 ALTERNATING-STRESS TESTS ON ROTATING BARS

c Riveted Lap Joints. For plates of about ½ in. in thickness, the specimens averaged about 65 to 70 per cent of the strength of the unperforated plate. Typical examples of the statical strength of large specimens of riveted and welded joints are given in Table 1.

OBSERVATIONS ON EXPERIMENTAL RESULTS

1 *Static Elasticity.* It will be observed that the statical tests made to determine the elasticity indicate that, in general, the combination of welded and unwelded material behaves practically homogeneously up to at least the elastic limit. Moreover, the experiments show that the process of welding is such that the stress

is distributed practically uniformly over the weld and also transmitted uniformly to the adjacent plates.

The material of the weld is practically pure iron, and from the tests made on a specimen composed entirely of the deposited material of a weld, it will be seen that for a given stress the weld stretches slightly more than mild steel. This property will enable any undue occurrence of load being transferred in a proper manner to adjacent portions of the structure. When, however, the stress exceeds the elastic limit and is so great that the extension grows continuously without increase of load, the welded material fails sooner than mild steel. But this disadvantage is of little practical importance in shipbuilding and may be regarded as negligible in the particular problem under consideration.

2 *Dynamic Elasticity.* In a structure, such as a ship, which is exposed to variations and reversal of stresses, it is extremely important to know whether the material to be used is likely to break down rapidly under such alternations and ranges of stress as are likely to be experienced. The modified Wöhler tests employed in the experiments certainly indicate, if considered solely by themselves, that whereas for a given number of alterations mild steel would withstand a range of stress of, say ± 10½ tons, the welded material might be expected to fail at about ± 6½ tons, a figure which is more nearly experienced in ordinary ship construction.

As already stated, the material in the weld appeared to be nearly pure iron, and experiments of repetitive stress show that wrought iron bars are likely to fail under a range of stress of perhaps ± 7 to 8 tons as compared with mild steel at ± 10 to 11 tons. The weld has to be deposited electrically and is subject to

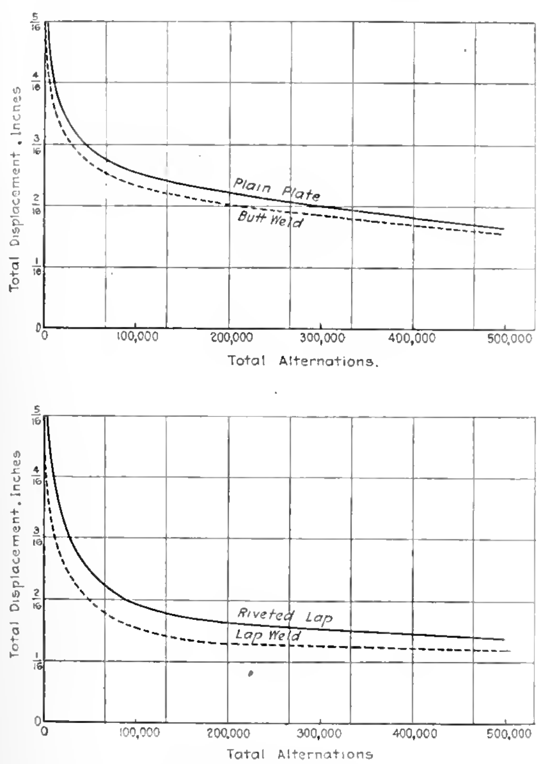

Fig. 8 Alternating-Stress Tests on Flat Stationary Plates

variations in workmanship; it would consequently be considered satisfactory if the material could withstand a range of stress of say ± 6½ tons. It would appear to be necessary to design the welded joints in such a manner that the amount of work likely to be thrown on the joint is as small as possible, and to meet such a condition a welded joint must be either lapped or strapped.

Lloyd's Rules for Electrically Welded Ships

In view of the satisfactory results of these tests, the Committee of Lloyd's Register of Shipping has decided that, under certain conditions, electric arc welding may be used in the main structure of a vessel and have adopted as a tentative measure, the following provisional rules for classification in Lloyd's Register Book of vessels electrically welded, subject to the notations "Experimental" and "Electrically Welded."

Tentative Regulations for the Application of Electric Arc Welding to Ship Construction

A—System of Welding and Workmanship

1 The system of welding proposed to be used must be approved and must comply with the regulations and tests laid down by the committee.

2 The process of manufacture of the electrodes must be such as to ensure reliability and uniformity in the finished article.

3 Specimens of the finished electrodes, together with specifications of the nature of the electrodes, must be supplied to the committee for purposes of record.

4 The committee's officers shall have access to the works where the electrodes are manufactured, and will investigate, from time to time

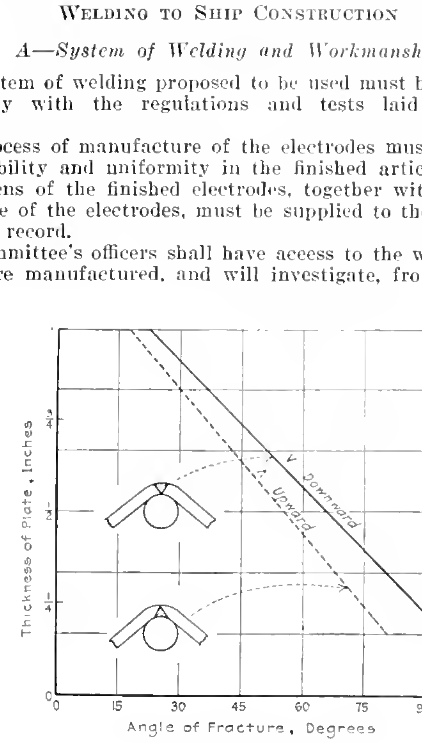

Fig. 9 Bending Tests

as may be necessary, the process of manufacture to insure that the electrodes are identical with the approved specimens.

5 Alterations from the process approved for the manufacture of electrodes shall not be made without the consent of the committee.

6 The regulations for the voltage and amperage to be used with each size of electrode, and for the size of electrode to be employed with different thicknesses of material to be joined, are to be approved by the committee.

7 The committee must be satisfied that the operators engaged are specially trained, and are experienced and efficient in the use of the welding system proposed to be employed.

8 Efficient supervisors of proved ability must be provided, and the proportion of supervisors to welders must be submitted for approval.

B—Details of Construction

9 The details of construction of the vessel and of the welds are to be submitted for approval.

10 Before welding, the surfaces to be joined must be fitted close to each other and the methods to be adopted for this purpose are to be approved.

11 All butt and edge connections are to be lapped or strapped.

12 With lapped connections the breadths of overlaps of butts and seams and the profiles of the welds are to be in accordance with the following table:

Thickness of plate, in.	*Width of overlay seam and butt, in.*	*Throat thickness, in.*
0.40 and under................	2¼	0.28
0.60 and under................	2½	0.38
0.80 and under................	2¾	0.48
1.00 and under................	3	0.50

Intermediate values may be obtained by direct interpolation, and for thicknesses below 0.40 in. the throat thickness is to be about 70 per cent of the thickness of the plate.

13 A "full weld" extends from the edge of a plate for a distance equal to the thickness of plate to be attached, and the minimum measurement from the inner edge of plate to the surface of weld is the throat thickness given in the table above.

14 A "light closing weld" is a single run of light welding worked continuously along the edge of the plate. Such a weld may, however, be interrupted where it crosses the connection of another member of the structure.

15 An "intermittent or tack weld" has short lengths of weld which are spaced three times the length of the weld from center to center of each short length of weld. Such tack welding may vary in amount of weld between a "full weld" and a "light closing weld."

16 The general character of welds is to be in accordance with the following table:

	Inside edge	*Outside edge*
a Butts of shell, deck and inner bottom plating .... *b* Butts of longitudinal girders and hatch coamings	Full Weld	Full Weld
c Edges of shell, deck and inner bottom plating .... *d* Butts and edges of bulkhead plating..	Light Weld	Full Weld
	Toe	Heel
e Frames to shell, reverse frames to frames and floors....... *f* Beams to decks....... *g* Longitudinal continuous angles....... *h* Side girders, bars to shell, intercostal plates, floors and inner bottom..... *i* Bulkhead stiffeners	Tack Weld	Light Weld

17 All bars required to be watertight are to have continuous welding on both flanges with tack welding at heel of bar.

18 The welded connections of beam, frame and other brackets are to be submitted for special consideration.

19 The committee may require, when considered necessary, additional attachment beyond that specified above, and the welding of all other parts is to be to their approval.

The rules are necessarily of a tentative nature and general in character and will be modified as further experience demands. It will be observed, however, that considerable importance is attached to the system of welding, type and process of manufacture of electrode, and to the employment of specially trained operators under supervisors of proved ability.

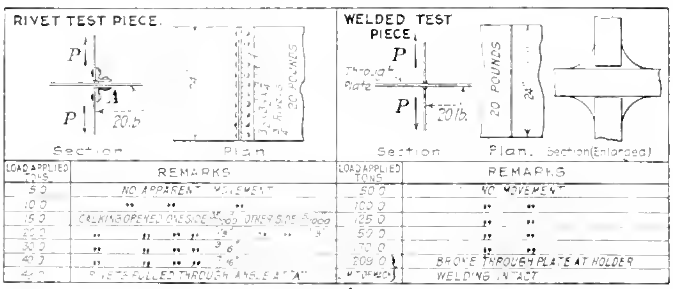

FIG. 10 COMPARATIVE TESTS ON BEARING STRENGTH OF WELDED AND RIVETED LUG ATTACHMENT

ELECTRICALLY WELDED VESSELS

The first vessel to be electrically welded so far as the writer is aware was the *Dorothea M. Geary*, a small launch 42 ft. long and of 11 ft. beam, built by the Geary Boiler Works at Ashtabula Harbor, Ohio, in 1915. The shell, which is of 8-lb. plating, is electrically welded throughout, the joints being butted and metallic-arc bare electrode used. The frames and bar keel are riveted to the shell. This little boat has been in service in the harbor since her completion, and no signs of distress or leakage have yet been noticed in any of the welded joints.

The barge recently completed at Richborough on the southeast coast of England, and referred to in the daily press as "the first rivetless ship," has attracted widespread attention. The construction of this barge was the sequence to a long series of successful tests on electrically welded joints carried out in England at the Admiralty dockyards and elsewhere, and will doubtless prove to be the stepping stone between the laboratory test stage and an actual full-powered ocean-going steamer yet to be built.

The barge in question is a non-propelled standard cross-channel transport barge 125 ft. between perpendiculars and 16 ft. beam, with a displacement of 275 tons. It differs in no way from the standard riveted type with lapped joints excepting that the seams of shell plating are arranged clinker fashion and joggled to permit of horizontal downward welding as much as possible. The hull is rectangular in section amidship with only the bilge plates curved. The shell plates are $\frac{1}{4}$ in. and 5/16 in. thick. It was erected in the ordinary manner with service bolts spaced from 10 in. to 15 in. apart, and after the joints were welded the bolts were removed and pins driven into the holes and welded up as it was desired to complete the structure entirely without rivets.

Five welders of considerable experience were employed on the work, using the "Quasi Arc" process with flux-covered electrodes. After a few initial difficulties had been overcome, an average speed of welding of 7 ft. per hr. was maintained, including overhead work which averaged from 3 to 6 ft. per hr. Altogether there were some 7000 linear ft. of welding and 3066 holes to be filled. The total cost of welding, which was £300 ($1500), was made up as follows: Electrodes, £178; current, £60; labor, £62. It is anticipated that the large proportion of this amount represented by cost of electrodes could be reduced by some 60 per cent with an increased output.

Careful check was kept of the total cost and the total man-hours of work involved, but a comparison with that of a similar riveted barge would be misleading, since the welded vessel was purely an experimental demonstration and no attempt was made to save material or to economize by the substitution of rivets in parts where this might have been cheaper or quicker than welding. Nevertheless it is estimated that 246 man-hours were saved over the riveted barge.

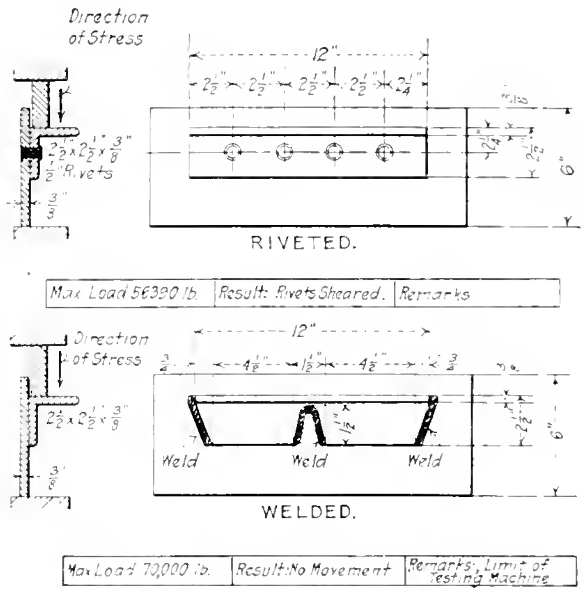

FIG. 11 RESULTS OF TESTS SHOWING RELATIVE VALUE OF CALKING AND WELDING

Since her completion she has been engaged in cross-channel service and with a full cargo of ammunition has experienced some exceptionally heavy weather, but has so far shown no signs of failure in the electrically welded joints.

WELDING AS AN OCCUPATION FOR DISABLED FIGHTERS

Apart from its importance to the shipbuilding and engineering professions, there is an impelling reason why the subject of this paper should at least command the sympathetic attention of all interested in the future of those men who in the defense of civilization have sacrificed their physical fitness to return to their former means of livelihood.

In the application of electric welding to ship construction a vast field of useful and honorable employment is opened up for temporarily or permanently disabled men on their discharge from the service or hospitals. We have seen that welding is not an arduous task; a man maimed by the loss of an arm or a leg can weld as well as the physical giant; it may be that he will weld better, for such work demands the conscientious application usually found among those whose occupations are limited as a result of physical impairment. In developing the welded ship, with all its economical possibilities, we may therefore be helped not a little by the consciousness of directly assisting in the solution of this greater problem of our national industrial economics in particular and of humanity in general.

Some Twentieth-Century Problems

By WILLIAM B. DICKSON,[1] NEW YORK, N. Y.

THE one clearly defined issue which seems to run through all history, is the eternal, irrepressible conflict between autocracy and democracy. And now America, the hope of a world grown weary with the ancient strife between democracy and autocracy, is facing anew the problem of the ages. How will she answer it? This is the theme to which I wish to direct your thoughts this evening, and I desire to say to you frankly in advance that I expect to raise some questions to which I have not been able to find completely satisfactory answers.

Let me read a recent poem by E. E. Miller:

The Question of All Time

Beside the road of time the gaunt Sphinx lay
  Half buried in the dust of cities dead.
  A mighty nation came with ringing tread;
The monster rose; the traveler stood at bay
And heard the riddle: "What is there to say
  When idlers feast and toilers lack for bread?"
  No answer came; a struggling gasp instead

Told that the Sphinx had clutched another prey
Empire on empire fell, the question still
  Unanswered, and today our young land hears
It asked. She hears; her lips half apart with will
  To speak; yet she is silent and appears
To halt in sudden doubt 'twixt two replies.
Still closer draws the Sphinx with baleful eyes.

My grandfather landed in Philadelphia in the autumn of 1830. He had come, in advance of his family, to see if America really was the promised land of which he had heard. He rode horseback to Pittsburgh, the journey requiring fourteen days. After spending some months in the Ohio Valley, he started back to Philadelphia on horseback in the depths of winter and suffered severe hardships in the crossing of the unbridged streams.

Not long ago, while thinking over some of the problems we are discussing this evening, I tried to picture what he would have thought if he could have foreseen the changed conditions in which his grandson would live. Let us suppose that he could have foreseen that in these latter days the journey from Philadelphia to Pittsburgh, which he made with such toil in fourteen days, would then be made in ten hours in luxurious ease. That instead of the single furrow turned by the oxteam, the food of the nation would be grown on farms where great tractors would drag a dozen plows and plow up an acre in seven minutes; and that, when the grain was ripe, it would be reaped, bound, threshed, and sacked by mechanical power, so that one man's labor would be equal to that of fifty men of his time. That instead of the slow hand process of carding, spinning, and weaving of cotton, wool and flax, great mills would be filled with power machinery that would multiply the product of man's labor a hundred fold. That all of the crude appliances of this time had been superseded by the marvelous labor-saving devices with which we are so familiar.

What would have been his conclusions as to the state of society in which his grandson would be privileged to live? Would he not have been justified in looking upon it as a golden age—an age in which the curse of poverty had been finally overcome? An age in which no honest man, willing to do his share in the community life, need ever have any apprehension of want for himself or his family? Has such a state been realized? If not, why?

Justin McCarthy, in his History of Our Own Times, tells of the horrible conditions under which women labored in English coal mines, when the seam of coal was so thin that they had to crawl on all fours for fourteen to sixteen hours a day, dragging after them the trucks loaded with coal. And this condition existed in the enlightened reign of good Queen Victoria.

I remember on my first visit to London, looking out of my hotel window early one morning in May, I saw a crowd of outcasts waiting for the park gates to be opened so that they could get in and throw their exhausted bodies on the damp grass. They had wandered the streets all night, and this was their only place of rest. I was informed that in London, on one night, as many as 35,000 homeless men, women and children had walked the streets —of whom it could be said, as was said of another outcast,—"He had not where to lay his head." And this condition was in the reign of good King Edward, and in the richest capital in the world.

Four years ago, in February 1915, as I sat down to breakfast, I opened the New York *Sun* and saw two headlines on the front page which made a lasting impression on my mind. At the upper left-hand corner was the announcement that a well-known American business man had bought four pictures for $250,000 each, or $1,000,000 in all. At the upper right-hand corner on the same page was the announcement that about 2000 men, women and children had stood in line the previous night in the cold rain to receive from the hand of charity a roll and cup of coffee, to keep them alive till morning. And these were not vicious men and women outcasts from society, but working people unable to obtain employment.

You will recall that this situation was so serious that Mayor Mitchel appointed a committee of prominent New York citizens to deal with this question of unemployment, of which Judge Gary was chairman.

As Louis F. Post says in his Ethics of Democracy—

> Though wealth is abundant, and wealth-producing power emulates Omnipotence, degrading poverty, and the more degrading fear of poverty, are distinguishing characteristics of civilized life. Instead of lifting all to better conditions of opportunity, man's triumphs over the forces of nature enormously enrich a few at the expense of the many.
>
> They have done little to increase the comforts of the toiling masses, even absolutely, but much to diminish their comforts relatively; and industrial liberty they have almost destroyed.
>
> The gulf between riches and poverty has not been filled in; it has been widened and deepened and made more of a hell than ever. So dreadful is the poverty of our time felt to be that it has inspired us all with a fear of it—a fear so terrifying that many more good people than would like to acknowledge their weakness, look upon the exchange of one's immortal soul for a fortune, as very like a bargain.

The Declaration of Independence proclaims as the inalienable birthright of every human being, the right to "life, liberty and the pursuit of happiness." I would like to amend the last expression to read: "the attainment of happiness," or, at least, a reasonable opportunity for its attainment.

James Mackaye has said: "Everywhere we are taught that life is sacred, that liberty is sacred, but where are we taught that happiness is sacred?" And yet, it is only because of their relation to happiness that these other things have a trace of sacredness.

You may be surprised to have me name as one of the causes of social unrest in our day the modern factory system, which we are accustomed to hear extolled to the skies as one of the most notable evidences of our progress toward a higher civilization. I confess approaching this subject with a good deal of hesitation, because it is not easy to reason this problem to a satisfactory conclusion. It is my earnest belief, however, that the man who, day after day, for the best years of his life, is a mere cog in the complex organizations which go to make up our modern factory system, is bound, in spite of himself, to be stunted mentally, morally and physically by the dreadful monotony of his task.

I have in mind such operations as wire-nail factories, where, amid the ceaseless deafening din, a man stands tending automatic machines pouring out an endless stream of nails. How much pride of achievement can be associated with such a task; or, even worse, the workers in the dust-laden, lung-destroying cement, acid, and fertilizer works?

The village blacksmith of our fathers' days who would shoe a horse in the morning and make a chain or build a wagon in the afternoon, was a better all-round citizen than the man who stands

[1] Vice-President Midvale Steel and Ordnance Company, 14 Wall St.

Address delivered before the Philadelphia Section of The American Society of Mechanical Engineers, January 28, 1919.

all day shut out from sunlight and fresh air, feeding some automatic machine, in the product of which he can have little pride. And this is not because the old-fashioned blacksmith was inherently a better man, but because of the inevitably narrowing effect of modern factory work.

I believe this very thing of which we are so proud is full of menace to our civilization, and that there was more of the joy of living among the rural population of 100 years ago than there is among a large proportion of the factory operatives today. The most important raw material of our factories is never mentioned in their system of accounting, namely, human lives and characters, but the finished product is made up of these elements just as really as of wood or steel or cotton. Cheap factory products would seem to be a vital necessity to our civilization, but if in producing them we are debasing our manhood and womanhood,—yes, and oh, the pity of it! that we must include our child workers also,—we are paying a fearful price for them.

In the mechanical arts, the world has progressed more in the past century than in all previous recorded history. If George Washington could have invited the Pharaoh of the Exodus to visit his plantation at Mount Vernon, he could not have shown him any advance in the art of agriculture over his own time, and with the exception of gunpowder, printing and the telescope, he could have shown him little or no advance in the mechanical arts. The steam engine, the cotton gin, the spinning jenny, the power loom, have revolutionized human life since then.

Most of the marvellous advances in applied science have been made in the memory of men still living,—such as the sewing machine, telegraph, telephone, phonograph, electricity in all its branches, internal-combustion engines, dynamite, airplanes and submarines.

In view of this wonderful acceleration in material progress, we should not be surprised to find a tendency toward a similar progress in the domain of human relationship, which, in some of its aspects, is as startling as were some of the inventions I have mentioned.

It is the tendency of the average business man to mistake mere inertia for true conservatism, and it is a sad comment on the power of inertia in human affairs that great advances in the science of human relationship seldom are achieved as the result of calm reasoning, but usually under the pressure of dire necessity or public danger. An English statesman once said that the British Parliament had enacted many just laws; but that it had enacted very few because they were just.

Many wonder at the social unrest which is so much in evidence, but as I contemplate recent history such as I have mentioned, my wonder is—not that men have become aroused, but that they were able so long to remain quiescent under such conditions.

In a completely natural society, every man, by reason of close and continuous contact with land and other natural resources would be an independent, self-sustaining unit. When a man has left this natural condition, whether voluntarily or otherwise, and has become the servant of another man, or other men, he has given up a natural right, and his employer has assumed an equivalent obligation. The fact that neither the employer nor the employee has been conscious of this exchange, and that both may have acted from purely selfish motives, does not alter the elemental fact, which, in the great national aggregate, constitutes the great unanswered problem of modern times: the elemental fact that is at the base of all social unrest.

The saying, "Taxation without representation is tyranny," epitomized the sentiment back of the American Revolution. Whether money is taken from a man by unjust taxation, or withheld from him by an unfair wage system, the principle remains the same. Lincoln, in one of his famous debates with Douglas said: "A house divided against itself cannot stand; this nation cannot continue to exist half slave and half free."

Political thinking has advanced with tremendous strides since then, so that as a result of the war with Germany, the nations seem ready to say: "This world cannot continue to exist half democratic and half autocratic." And while this is true in the domain of politics, it is no less so in industry. Our past history is full of instances where men in control of large aggregations of capital have been guilty of grave abuses against the public welfare and against the most elementary principles of morality. These autocrats of capital have been partly balanced (whether as an effect or a cause, would depend upon your point of view) by equally autocratic and irresponsible labor leaders, who have not hesitated to use force in its vilest forms in order to win their ends.

I do not unreservedly denounce the use of force, as to do so I would have to include in such a sweeping condemnation some of the noblest of mankind, who, as a last resort, and to redress just grievances, have not hesitated to use it. But this, which should be reserved for the holiest uses, has been prostituted by labor demagogues to achieve the most trivial ends. The only way out of this senseless conflict between capital and labor is for employers to realize that the day of industrial democracy has dawned, and that "The establishment of wage rates and other conditions of employment without representation is tyranny" also.

Much has been done by benevolent employers to improve working conditions, but however conditions may be improved, the right of the workmen to collective bargaining must be recognized as a legitimate outgrowth of American ideals. The individual workman, dependent on his own strength and resources, cannot hope to bargain on equal terms with the corporation. If he cannot do so, and is debarred from association with his fellow-workmen, he is no longer a free man but a serf: and the serf has no place in the future of America.

Many years ago a noted steel man was asked which was the most important factor in his business, labor, capital, or management. His reply was in the form of a question: "Which is the most important leg on a three-legged stool?" While the above conclusion as to the equality and interdependence of these three factors has been generally accepted as a theory, in very few instances has it been given practical effect.

I believe that the greatest task to which American employers must address themselves is the devising of practical ways in which labor can be given the full recognition to which, as an equal partner, it is entitled. I make this statement with absolute confidence in the fair-mindedness of the American workingman when he is fully informed and is entirely free to act. If I did not have this confidence, I would despair of the future of our free institutions. I believe that one of the first steps necessary to inspire the workmen with confidence in the sincerity of the employers' recognition of the proper status of labor is the adoption of a fair system of collective bargaining. I am glad to say that the company with which I am connected has recognized this right, and has established what I believe to be the most democratic system of collective bargaining which has ever been devised.

Some of you may ask what is to become of the sacred freedom of contract under such a system? I answer—The same thing which has happened to many other seeming natural rights which the individual has sacrificed for the common good.

Consider for a moment the natural rights which you have resigned as compared with the residents of Philadelphia only two or three generations back. Can you imagine some doughty individualist of those days submitting suddenly and gracefully to all of the laws and ordinances of the municipality, the state, and the Federal Government, to which you give not only obedience, but also assent? Would your great-grandfather have tamely submitted to compulsory vaccination, to restricted child labor, to the haughty traffic policemen and your one-way streets; to all of the restrictions on your personal liberty which you recognize as essential to the common good? None of these questions can be answered separate and apart from the problems of our complex civilization.

I also believe that as a further natural development of democratic ideals, systems of profit sharing with employees must be worked out and adopted. One of the earliest records we have of the employment of one man by another for wages, is that of an Arabian sheik who employed a young man to care for his flocks. It is interesting to note that while at first he was a mere hireling, the relationship eventually changed into one of profit sharing. I refer to the story of Laban and Jacob as recorded in the thirtieth chapter of Genesis. If you look this up and find that the em-

ployee "put one over" on his employer, I hope you will not on that account condemn the principle.

No system could be devised which would be applicable to every industry, but this basic principle would be common to all. Capital can, with reasonable care, be invested so as to return, say, 5 per cent, with little or no risk to the principal. Where it is invested in a business where risk of depreciation or loss of the principal is a constant factor, as it is in most industries, it should have the first call on the profits to an amount in excess of 5 per cent to fully cover this risk. This percentage would, of course, differ widely from that of national bank stock up to the manufacture of explosives. If I were asked to suggest a tentative plan for the average well-established steel company, I would first give the stockholders 10 per cent on their stock and divide the surplus over this amount equally between the stockholders and the employees, including the management.

In other words, capital, management and labor are each entitled to wages at current rates, and to a sufficient share of the profits to insure permanency. Capital, under the example cited, would receive 5 per cent as wages and an additional 5 per cent as insurance. Management would receive salaries which, presumably, would be large enough to enable each person to avail himself of modern life, accident and health insurance. Labor would receive wages at current rates and would be insured by the workmen's compensation law, maintained by taxation of industries. After the payment of these wages and insurance, the remaining profit should be divided equally between capital on one hand and management and labor on the other.

And now, in conclusion, in what spirit shall we deal with these problems—that of class consciousness, or in that broader spirit of human brotherhood which is so gloriously set forth in the writings of the loving-hearted Lincoln—"With malice toward none—with charity for all"?

Herr Ballin, one of the wisest of the former counselors of the Kaiser, in a recently published letter ridiculed the idea that Americans as a nation were mammon worshippers, and expressed the opinion, based on long years of close business association, that we were, on the contrary, above everything a nation of idealists. To prove that this has been true in the past, we need only to point to the Civil War, waged for the great ideal of human freedom; the part we played in the Boxer Rebellion, in returning to China our share of the indemnity exacted from her; the Spanish War, to end the intolerable conditions in Cuba and to establish her as a self-governing nation; and lastly, our part in this great war in the defense of civilization, in which we engaged technically, perhaps, because our legal rights were violated, but in fact because we recognized that it was a death struggle between autocracy and democracy, and one in which the leading democracy must play a noble part or be forever put to shame.

And in this holy war, in which the ideals for which America stands have been so gloriously triumphant, the sons of employers and workmen have marched shoulder to shoulder, and many of them sleep together today in the same patriotic graves in the soil of France, hallowed by their sacrifices. Let us, in the same spirit of brotherhood, grapple with the problems of peace and help to usher in the dawn of an industrial democracy which will give fuller recognition to the thought expressed by Burns:

> The rank is but the guinea stamp,
> A man's a man for a' that.

The speaker prefaced his address with a brief statement of his experience in order to show that he had at least had the opportunity to study certain present-day social problems at close range. Starting when a boy as a manual worker in the Homestead Steel Works, he had been fortunate in receiving rapid and continuous promotion, and eighteen years later had become one of the junior Carnegie partners. He had been vice-president of the U. S. Steel Corporation for the first ten years of its existence. In 1915, after a brief retirement, he had returned to active business life as an officer of the Midvale Steel and Ordnance Company.

He had been reproached for his attitude on social questions by his friends and associates, and had at one time or another been called a socialist, an anarchist, a Bolshevik, a radical. He was glad to be termed the latter, however, provided that Gladstone's definition was accepted:

Conservatism—Distrust of the people, tempered by fear.
Liberalism—Trust of the people, tempered by prudence.
A Radical—A Liberal in earnest.

He wanted to disclaim being a mere sentimentalist. He had had to deal with hard facts all his life, and he believed that he was able to keep his feet on the ground, even if his head might seem to be in the clouds.

Readjustment of Labor

The Readjustment Committee of the Merchants and Manufacturers' Association of Baltimore has rendered a report on the labor conditions in Maryland. A brief summary of their remarks and suggestions, which were classified under 11 different headings, is as follows:

1 *Right kind of man can get a job.* Employers now are not driven to the extremity of submitting to any kind of labor as during the war, and they can expect in return for a high wage an equal measure of productiveness.

2 *No use to look for war wages in normal shops.* Times are normal again and workers cannot in reason expect the excessively high wages of munition and other war plants.

3 *Must beat down the high cost of living.* Alliance of capital and labor is absolutely essential to bring about a reduction in food prices.

4 *How about the soldier laborer? How could he be handled?* Proximity of military places to Baltimore causes many of the discharged soldiers to pass through the city on their way home. They plunge into pleasures and accompanying excesses and find themselves stranded. Then they look for work under conditions to their disadvantage. This demoralizes the labor market.

5 *Must reëmploy resident returning soldiers.* It is suggested that the public, through some community committee, should be apprised of all those employers who turn their backs upon the men who responded to the call of their country.

6 *What to do to take care of the unemployed.* If unemployment becomes ominous, it becomes a community problem, and the state, the city and the counties should work out plans for public improvements and should offer work to those who might otherwise suffer.

7 *Women workers who do not have to work for a living.* If these women were induced solely by patriotic motives to take jobs during the war, why will not the same lofty patriotism, in times of peace, induce them to surrender the jobs in favor of men and other women whose families will go hungry if employment is not found?

8 *Returning munitions and shipbuilding laborers vs. out-of-town soldiers.* During the urgent days of the war great patriotic drives were made all over the country to make workmen understand that it was their primary duty to give up all else in order to promote rapid making of munitions and the speedy building of ships. That being true, the munition worker or shipbuilder who seeks a return to his old employment under terms and conditions commensurate with the peace situation is entitled to consideration ahead of the out-of-town man in uniform.

9 *Not fair to fill the places of local labor with soldiers who belong elsewhere.* The committee is of opinion that when a nonresident soldier makes application for employment to a local United States Employment Service, that Service should endeavor to place him at work in the city or state from whence he came.

10 *Industry should not drive labor into the arms of dangerous allies.* Only a genuine coöperative relationship between industrial employers and labor can prevent a closer alliance of the Non-Partisan League, an organization of radical agriculturists, with industrial labor. Narrow-minded policies of American employers will precipitate the spread of the socialistic tendencies that have gripped North Dakota.

11 *How to make high wages certain.* Employers are willing to pay an average wage to an average worker, but why should not the worker be allowed to progress in the range of his wage earnings in proportion to his individual productive powers?

The Engineer as a Citizen

A Symposium on His Civic Responsibility and Relation to Legislation, to Administration, to Public Opinion and to Production and Distribution

A WELL-ATTENDED meeting of engineers of the metropolitan district was held on the evening of March 26 at the Engineering Societies Building, New York City, the purpose of the gathering being the discussion of the place and duty of the engineer in the community. The meeting was held under the general auspices of the New York sections of the national mining, mechanical and automotive engineers' societies, and the members of fifteen other engineering and chemical societies were invited to attend and take part in the discussion. Gano Dunn presided and introductory addresses were made by Philip N. Moore, Calvert Townley, Nelson P. Lewis, Spencer Miller and Comfort A. Adams. An active and extended discussion followed, one important result of which was that resolutions were adopted looking to the organization of a New York local engineering society composed of the local sections of the national societies and of other local engineering organizations. Abstracts of the addresses and the discussion which followed their presentation are given below.

The Civic Responsibility of the Engineer

PHILIP N. MOORE

The engineer, waking from long sleep of indifference and self-content, satisfied with himself in his professionad successes, has suddenly waked to the fact that he is not politically potent. He has not counted as a class politically because he has not served politically; he has not, save in rare cases, developed in himself the political sense. In the professional heart-searching, momently the dominant mood, he seeks the reason.

Broadly speaking, the answer is plain. He has not cared enough to exert himself personally or professionally to attain an end which now at last seems to him worth while and vital.

Given like heredity and culture, there is no inherent reason why an engineer should react differently from any other citizen to the patriotic call or civic responsibility. But, unfortunately, things have combined to leave him too often unwanted and uncalled. What are these things?

First, lack of local attachments. With few exceptions, the engineer's tasks are scattered countrywide, or worldwide, and mostly are those of construction, which, completed, he goes his way to build again. He works under strain, he has little time to forgather with his fellows, or to think in terms of political or national interest and service, save as great emergencies come, like that of the late war. And without local responsibilities a man feels little sense of civic duty and finds less opportunity for participation in national questions.

Second, a large proportion of the total body of engineers serve the great business consolidations, many of which have interests adverse to the public, or by their very size induce criticism and political attack, and in self-defense they think they must hold their staffs to strict neutrality on all public questions.

Third, the engineer's training has failed to teach that the greatest task of all is the ability to persuade men, and unwillingness or incapacity to enter public discussions, either through modesty or lack of readiness, have held him back. False professional pride, and the same indifference which holds back many high-class men through unwillingness to mingle with and rub shoulders against the great majority, have also deterred him.

Fourth, the past habits of the great organizations which the engineer forms (and which voice his profession) to hold themselves aloof from political affairs as collectively unethical.

What shall be the remedy for the engineer's isolation? It is within himself. He must realize that the duty is in him first and then in his society. By virtue of his exact knowledge of the things which build so large a share of civic affairs, for so much is engineering, he is particularly fitted to render expert advice and service.

We need fearless men who in the market place and from the housetop shall proclaim to the world: That since the beginning of history brains have ruled brawn; that the brain deserves, and in the ultimate will inevitably receive, greater reward than the hand; and that any proposed condition which puts brawn over brains plans the pyramid on its apex and necessarily is one of unstable equilibrium.

These are a few of the things we can preach, and because we fear no political backfire. We have no fences to mend. We can stand in the open and say everlasting truths, and the time will come when some men may believe them.

The Relation of the Engineer to Legislation

CALVERT TOWNLEY

What the attitude of the engineer should be toward legislation is a question that has been debated with considerable vigor for many years. Opinions differ widely, and range all the way from that of the ultra-conservative, who believes that the engineer should have nothing whatever to do with legislation or politics, to that of the ultra-radical, who thinks that he should direct all legislation—in fact, that no government function should be exercised except under his direction.

It may help us to visualize the present situation if we examine briefly one or two of the ways in which engineers have attempted to influence legislation heretofore. In 1911 the American Institute of Electrical Engineers, on invitation from the National Waterways Commission, sent a committee to Washington to appear before the Commission. The committee was assisted by a special advisory committee, and held several meetings before proceeding to Washington in order to determine just what should be their policy and what sort of a presentment they should make. It was decided that the committee should confine itself strictly to a statement of engineering and allied facts which engineers were peculiarly competent to testify and which were beyond the field of controversy. They were instructed to refrain from expressing views as to the wording of any legislation or to give opinions regarding legal matters.

In 1911 a bill was introduced in the New York state legislature to license engineers and which aroused the alarm and stirred up the strenuous opposition of the four national engineering societies. A joint committee was appointed from these societies, and from the Institute of Naval Architects and Marine Engineers as well. This committee sent a strong representation to Albany, which appeared before the Legislative Committee and vigorously opposed and assisted in defeating this attempted legislation. It was found desirable to take somewhat similar action again in 1913. Feeling that it would be advantageous to have some means of coöperation among the national engineering societies, this committee was continued under the title of a Joint National Committee of Engineering Societies and continued to serve for several years, its activities, however, not by any means being confined to legislative matters. One of its functions was to serve with respect to the National Engineering Congress held in California in 1915, and out of it grew the discussion which finally resulted in the organization of the Engineering Council.

The Engineering Council has been in existence since May 1917. It has been in receipt of many requests to favor or oppose legislation, and this legislation is by no means confined to questions of engineering, but covers every sort of subject from the fixing of a minimum wage for labor up to the organization of the Army for the conduct of war.

The Engineering Council was created to speak for its constit-

uent societies on matters of common concern to engineers and to afford a means for joint action when desirable. Its by-laws give it wide latitude, and there have been no limiting instructions issued to its delegates by the appointing bodies. The Council has therefore had to determine upon its own line of action, and it is by no means certain what that should be with respect to legislation.

It has been my lot to have to do with this question for a number of years, and while I have earnestly sought to get the opinions of my engineering friends and to act upon them, I confess that I do not know what engineers want, and therefore what our policy should actually be. Of course, we believe in ourselves. We believe that an engineer's training, designed as it is to make him think clearly, to deal with essential facts and to arrive at logical conclusions regardless of outside influence, peculiarly qualifies him to express opinions on legislative as on other subjects, but we shall have to choose which of two places to occupy. Shall we be a united body of technical men, speaking only with deliberation and a certain amount of proper dignity regarding subjects which the public recognizes us as qualified to speak upon, or shall we be as a body of somewhere from 30,000 to 100,000 citizens who have a common interest and desire to exert political pressure by reason of our numbers?

I would like to think that we could combine these two positions, but my logic tells me that we cannot. Personally I believe we should not try to influence legislation which concerns us only as citizens, but if we undertake the task at all, we should concentrate our efforts on certain specific lines and thereby stand a better chance of having them prove effective.

The Relation of the Engineer to Administration

Nelson P. Lewis

Heads of great industrial enterprises, transportation companies, and all other public-service activities, are required to perform functions which are largely administrative. Such places were once almost always filled by business men or lawyers; later by men who had come up from the ranks, hard-headed men who had begun as boys and passed through the various branches or divisions of the work and had demonstrated qualities of men, leadership and executive capacity, but seldom were they of technical education. During recent years, however, we have seen such places more frequently filled by men who knew the science as well as the art of the business, keeping in mind the old distinction between the two, namely, that science teaches us to know and art to do. There have been many conspicuous instances where spectacular success has been achieved by young men of this type, a success which would only have been gained under the former system through long service, beginning at the very bottom and slowly mastering the details.

But the term "administration," as commonly used and understood, relates more particularly to public business; business of the city, state and nation. From this type of administration the engineer has been more completely excluded than in the case of industrial concerns or public-service corporations. In this exclusion the engineer himself has appeared to acquiesce. He has been so long accustomed to doing things when he is told, as he is told, and because he is told by those whose function he has thought it to be to determine general plans and policies that he is in no small degree responsible for the idea which has been generally prevalent, that the duty of the engineer is simply to carry out the ideas and policies of others. But if it be admitted, as it must, that what is commonly called the administration of public business is largely the formulation and execution of engineering projects, why should not engineers themselves take a conspicuous part in their formulation as well as their execution?

The machinery of municipal administration, as prescribed by city charters, has usually been very cumbersome and ill adapted to meet emergent conditions. In 1900 the city of Galveston was practically wrecked by a violent storm and tidal wave. The city was already in a bad financial condition and the municipal government was unable to cope with the situation. In order to meet existing conditions, a form of commission government was adopted under which the entire management of the city's affairs was placed in the hands of five men. So successful was the plan that within a dozen years it had been adopted by about four hundred cities and towns within the United States.

In 1913 the city of Dayton went a step further and adopted what is known as the commission-manager plan. This also consisted of a commission of five citizens, elected at large, who constituted the governing body, but they appoint a chief administrative officer, designated as the city manager. It will be noted that these two forward steps in municipal government were taken by cities which had suffered great disasters.

Thus was developed a public office which the engineer with executive capacity is especially well qualified to fill, and that this opinion is held by those responsible for the selection of the managing executives is evidenced by an examination of the list of city managers who have been appointed. Of the 124 cities now operating under some form of the city-manager plan, the speaker has been able to secure information as to the previous experience and training of 88 of the managers, the classification being as follows:

50 professional engineers
9 merchants
6 minor city officials
5 general business
3 superintendents of construction
2 journalists
13 miscellaneous (these including one each of contractor, railroad president, railroad purchasing agent, public-utility manager, professor of government, training school for public service, office manager, league secretary, real estate, lawyer, physician, broker and plumber).

But what about the training of the engineer to fit him for such positions? Business sense is certainly an essential qualification for success in such work as the management of a city, a public-service corporation or an industrial enterprise. Are the courses given in our engineering schools calculated to fit him for these most attractive fields of activity? We will be told that all of the time of the student is required to enable him to cover the strictly technical curriculum, and that if such things as culture and business courses are to be added, the period of training will have to be lengthened or some of the technical courses will have to be curtailed or omitted. Perhaps this would not be as serious a loss as professional educators imagine, while it would broaden the student and might account for the difference between success and failure in administrative positions.

The Relation of the Engineer to Public Opinion

Spencer Miller

The engineer is assuming an ever larger position in public life, and in spite of himself he is at the very center of life. The more we realize this great truth, the more seriously do we contemplate our responsibilities. This thought fills some with pride and others with humility. Eliminate the engineer from the world and civilization would soon pass through other Dark Ages comparable with savagery and barbarism. It is clear, therefore, that we, individually and collectively, should make every possible effort to mold public opinion in the right direction, especially at present to counteract the propaganda of those stirring up class hatred. Even today the engineer stands, with all law-abiding citizens, facing the dark cloud of Bolshevism—not timidly, not indifferently, but in full strength, courage and faith that Bolshevism cannot survive in America because it stands squarely against the code of morals upon which our civilization was founded.

We observe that the engineer is successful in public life because of his technical training and his upright character. But who may say that a well-trained lawyer with upright character to his credit would not make an equally good public servant? Is it not evident that both engineer and lawyer are needed in public and political life and are any comparisons advantageous?

A Congress half lawyer and half engineer surely would be superior to one all lawyer or all engineer. Do we not also recognize

that experienced business men, manufacturers and farmers of upright character are also required to serve the nation in Senate and Congress?

What is the relative importance of the training of an engineer as one element and his upright character as the remaining element? Let us look for an answer in the recent struggle to find that element which President Wilson so aptly called "the very stuff of victory."

The program for the United States involved billions upon billions of money. Ships by the thousands, airplanes by the thousands, guns by the hundreds of thousands, shells by the millions, tanks in hundred thousand lots, and several million men besides. A small fraction of these materials of war ever arrived in France, and yet both France and England frankly acknowledge that our troops turned the scales against Germany. What, then, is the answer? Who won the war? What won the war? The answer to the riddle is the same that Napoleon announced one hundred years ago: "The relation of morale to materials of war is as three to one." And Marshall Foch only last week said, "Faith won the war." Both faith and morale are things of the spirit. If the stuff of victory at arms is largely a thing of spirit, why is it not also true of any victory in engineering. Are not the greatest engineering victories due more to perseverance, industry, good habits, courage, pluck, steadfastness than to simple engineering training? Is it not the spirit, after all, that wins all victories?

If the engineer finds that in the complete fulfillment of his life work about one-quarter is material and the remainder spiritual, should not engineering societies make adequate recognition of this important fact? Is not morale as important to the engineer as to the soldier? Is it not as important to an engineering association as it is to a military division? If these facts are conceded, then can we refuse to give the fullest and most complete consideration to the development of these traits among engineers?

The Relation of the Engineer to Production and Distribution

Comfort A. Adams

Two of three of the speakers have spoken of engineering education, and the last speaker spoke of matters of character and spirit. I have long been concerned with engineering education, and certain things have been impressed very vigorously on my mind, and one of them is that it is not the curriculum and the subjects that are taught that count; it is absolutely and solely the way in which they are taught. That is really a conviction so strong in my mind that I am not concerned with the subjects that are taught, but vastly concerned with the men who teach them.

Coming now to the subject assigned to me on the program, let me say that the civilized world is today facing a crisis second to none within the memory of this generation or of many preceding generations. Discontent is rampant throughout the proletariat in many European countries, and is spreading rapidly in our own.

The situation may be stated roughly as follows: Labor feels that in the past it has not had its fair share of the wealth it has helped to create; it wants, is beginning to demand, and in some instances is getting so much, that the balance will soon be a minus quantity.

What are we going to do about it? Shall we sit tight, and because we are comfortable satisfy ourselves by criticizing vociferously the discontented because of their unreasonable demands, or shall we use our brains and training and at least to try to remove the cause, and to meet the situation intelligently? We are engineers, and the machinery of production and distribution is largely of our making and largely in our hands; is it not possible that this machinery can be so improved as to increase the productivity of labor and thus make possible a really living wage and still have a fair return for capital?

"But," I hear you say, "that is our normal job—we are doing that all the time, and as rapidly as possible; moreover, the United States already leads the world in that direction."

In answer may I point out a few facts: First, our industrial success has been due in considerable part to our enormous natural resources, the cream of which we have been squandering in prodigal fashion, and also in part to our exploitation of cheap foreign labor, for which exploitation we may have to pay a very high price, as it is in that group that most of the active discontent is found.

Second, in many of our old established industries there still remain many grossly inefficient, almost traditional, processes which we accept without thinking, because "it has always been done that way."

Third, and this is my chief point, there still remains an almost untouched field of possibilities in the elimination of our present excessively expensive system of competition.

One instance of this wastefulness which has come under my close observation during the past year is in the field of electric welding. Here a dozen or fifteen manufacturers were each found selling welding apparatus under claims relating solely to the characteristics of the electric machine which supplied the current. The claims were so conflicting that no ordinary purchaser or customer could possibly come to any sane conclusion as to the best apparatus to purchase. And, as a matter of fact, even of all the factors which go to make up a good weld, the characteristics of the electric machine are practically of the least importance.

I can cite specific instances in this field where the cost of accomplishing a certain result was two or three times as great as the reasonable cost might well have been, and others in which the whole expense involved was practically thrown away; and although the problem of the electric weld is not a simple one, still information was available and knowledge was available of the art which, if collected together, under any reasonable coöperative system, would have largely eliminated the wastefulness mentioned. In other words, the answer to this problem is well covered by the one word "coöperation"—coöperation in research, in standardization, and even in some cases in design.

The chief obstacles to this are traditional fears as to the loss of independence and initiative, and the distrust of our competitors. I only wish that I might by some telepathic process convey to you my firm conviction after some experience, much thought and study, that these fears are largely ungrounded, that the result of such thorough-going coöperation as here urged is sure to be a gain to all concerned, and that under such a system real merit would prevail even more than now.

Finally, may I add a plea that we engineers, whose normal work is so much concerned with organization in industry, accept as a part of our responsibility as citizens the broader problems relating to the organization of society, that we face the facts fairly and prepare to take an intelligent step forward, rather than wait until the great tank of discontent has gained momentum enough to crush us and all that we represent.

DISCUSSION

S. N. Castle, who opened the discussion, said that the speakers had truly voiced the feeling instinctive to the engineer—the desire to serve. But to enable him to serve others, he must first serve himself. At present a hedonist in his individualism, he must learn to present, as an engineer, a single and united front.

This must undoubtedly come through organization; but how? what? Highly differentiated though the engineer might be, the lawyer was far more so; yet he spoke as with one voice—as a lawyer, and with and through his bar association. Soo, too, did the merchant who also had his associations and chambers of commerce. The engineer, however, still talked confusedly, with many tongues.

The problem, he believed, was susceptible of four general solutions: (1) A merger of the existing societies into a single national organization (with such local sections as appear desirable) capable of serving equally all technicians, whether artisans, mathematical engineers, applied scientists, or research scientists; in other words, create definitely an Institute of Industrial Sciences; (2) a New York engineering society or metropolitan association of engineers, comprising the New York section of the national societies and local engineering societies; (3) a joint engineering council, to be composed of definite delegates from

the New York sections or local societies; and (4) interlocking committees in the national societies.

Daniel Turner, in discussing Mr. Castle's recommendations, urged that no new organization be formed, inasmuch as a suitable organization already was in existence.

"Why not let the American Association of Engineers become the standard bearer of the affiliated and united engineering societies?" he said. "Why not help to establish its destinies? Why start another organization, which means more differentiation and still further dispersion of our energies? Service is one thing, being servants in the situation is quite another thing. The logic of the situation points inevitably in one direction—there is only one answer: In squads, all of our efforts, just as in the past, are doomed to fail; as a great army of engineers we would be irresistible."

Frank Skinner believed that the national and local methods proposed by Mr. Castle could be combined. There were already several hundred different organizations for the 50,000-odd accredited engineers of the country, and he urged a federation of these rather than the formation of a new body in which the rivalries and just pride of the now existing societies would be lost. The engineer was he who actually carried to successful fruition the work of the designer, the mathemetician and the pure scientist, and the Association of General Contractors of America, recently formed in Chicago, he believed was better adapted to deal with their necessities than any precedent organization.

J. E. Johnson, Jr., made a plea for a change in the curricula of the engineering schools in order that more attention might be paid to the human side of engineering and to the subject of finance. In the matter of organization he believed that both the national and local societies had their proper place in the scheme of things. The Engineering Council was an associated activity that should be endowed with greater power, made more national in its scope and composed of men who would do their full share of the work.

H. A. Pratt told of the effective work carried on by local associations of engineers of all branches in San Francisco, Cleveland and Philadelphia, and urged strongly a similar organization for New York City.

Lieut. George S. Van Gilder expressed the opinion that the whole situation could be analyzed as a feeling of unrest. No doubt, he said, the engineer had occupied a very insular position toward society, and the crisis of the past two or three years having gone by, he was now confronted with a new crisis which he feels intensively, but is hardly able to express.

The unemployment problem might easily become a menace, and his suggestion was that each engineering society organize a unit for the purpose of studying sociological questions from an engineering standpoint, and that a council of these units be formed for the discussion of the problems arising at the different local branches.

In order that some definite action might be taken as a result of the meeting, C. F. Scott offered the following resolution, which was later adopted:

Whereas, All engineers, as citizens, should invite the fullest coöperation; and

Whereas, Complete coördination of the engineering profession, as a whole, is essential for the best interests of the community; and

Whereas, It is the sense of this meeting that some program be formulated whereby closer coöperation between engineers may be obtained; therefore, be it

Resolved, that the Secretary of this meeting be and is hereby directed to so notify the secretaries of the several societies or local sections of the societies here represented tonight with the request that the several secretaries transmit this resolution to their respective local membership, together with an invitation to said local membership to appoint a delegate to attend a joint conference, with a view to organizing so as to obtain closer coöperation between engineers, particularly between the engineers resident in the Metropolitan District, whereby they may become more potent in fulfilling their responsibilities as citizens.

C. A. Doremus, a member of the Société de Chimie Industrielle and the Society of Chemical Industry, while not officially representing these societies, was nevertheless of the opinion that they would coöperate in any movement to make the engineering professions and scientific pursuits of more weight and greater influence.

Jesse M. Smith, one of the charter members of the American Institute of Electrical Engineers and a past-president and one of the earlier members of The American Society of Mechanical Engineers, spoke of the constantly increasing coöperation of the four national societies brought together in close relations through the United Engineering Society. Up to the present time this society had been scarcely more than a holding corporation, but its constitution was such that engineers of all branches might come together under its organization. A single society for the engineering profession seemed to him inevitable.

At the request of the chair a letter from H. H. Vaughan, of Montreal, Canada, was read, which briefly outlined the organization of the Engineering Institute of Canada. This society is composed of engineers belonging to all branches of the profession, and is the only national engineering society in Canada. Its organization is such that the society can represent the engineers with equal ease in city, town or province, or, if necessary, all the engineers in the Dominion.

Farley Osgood thought that the principal reason why engineers were not more generally accorded recognition was their own individual lack of interest in outside things. This was particularly true of young engineers, and he believed if educators were to teach them as much of a curriculum as was necessary, and also find out what the minds of the various young men might be adapted to other than engineering, that they would help them broaden themselves along these lines also, so that when they started out in the practice of their profession they would carry in parallel with it some civic work, some outside interest.

As an indication that the subject of the evening was one receiving nation-wide consideration, Philip N. Moore called attention to the work of the National Service Committee of the Engineering Council. "This Committee," he said, "has taken as its first task one which is unanimously welcomed by the engineers of the country as a great public need, namely, the establishment of a National Department of Public Works, where under one head the different engineering functions of the United States can be correlated and which today are scattered under twenty-two bureaus and six cabinet officers. In undertaking that task, the National Service Committee has called a meeting of delegates from all the engineering societies of the United States of which they can learn the existence, and requested them to send delegates to a meeting in Chicago, April 23 to 25, prepared to discuss a concrete, definite plan for the establishment of a National Department of Public Works. Through one of the secretaries of one of the organizations a questionnaire has been issued to all of the organizations interested on which they request organization action.

"Further, I happened to learn in Washington that the idea itself will be more than gladly welcomed. That meeting of engineers in Chicago will probably be the most representative meeting of engineers ever gathered together in this country. From it your speaker personally feels that there will come great good, and it is a great deal of pleasure for him to tell you of it in advance of the public statement of the meeting, because it may have some influence on your decision in the matters now here before you."

Louis C. Marburg, Chairman of the A.S.M.E. Committee on Aims and Organization, said that the problems under discussion were so great that the four national societies had appointed committees on development and on aims and organization to secure, if possible, a crystallization of opinion as to what the ideals of the engineering profession and the ideals of the engineering societies should be. There were hundreds of engineering societies in the country and an utter lack of coördination between them as to their efforts along lines of public service and public uplift. The discussion of the evening should be spread everywhere, it should be taken up by all the national engineering societies and by all the local engineering societies. The crystallization of ideas as to what the purposes and aims are to be must be secured before the machinery for carrying them out can be proposed. To this end he offered the following statement and resolutions:

Around us is a world on which, during the past two generations,

(*Concluded on page 496*)

ELECTRIC ARC WELDING

By F. A. ANDERSON,[1] SAN FRANCISCO, CAL.

It is only a few years ago that the subject of electric arc welding would have aroused but little interest, and yet today the art is engaging the attention of many men standing high in the engineering profession.

At the present time electric welding may be divided into two general classes, resistance welding and arc welding. The former had its inception some thirty years ago, and has been practiced more or less continuously ever since, gaining in popularity as its many applications have proved themselves valuable.

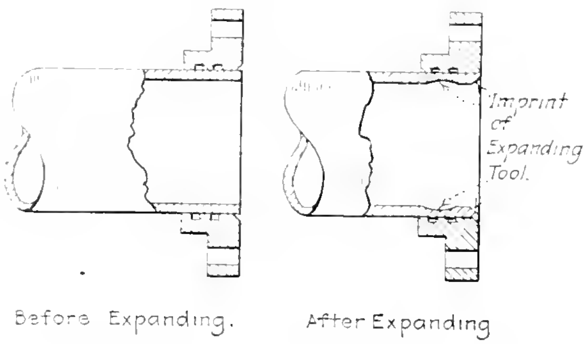

Fig. 1 Method of Expanding Pipe into Flange

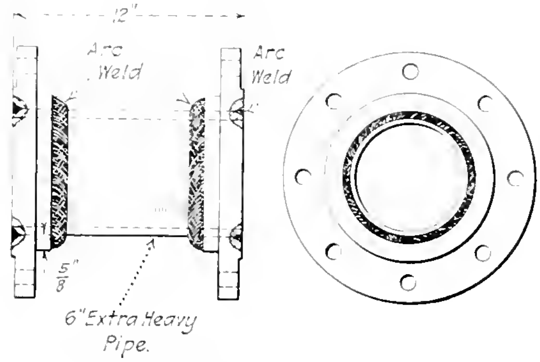

Fig. 2 Welding Required on 6-in. Steel Flange

In this process the necessary heat is produced by current flow through the high resistance of metals in contact, and when the proper heat is obtained the completion of the weld is accomplished by the application of pressure sufficient to unite the molten masses into one. This is the fundamental principle of the many spot- and butt-welding processes in use today.

Arc welding is about twenty years old and was probably first introduced by Zerener, who devised the means of holding two carbons of opposite polarity in a V form and employing an electric magnet for forcing the arc toward the work. The desired heat was thus obtained directly on the metal to be welded, and welding wire was fed into the arc, filling the void and completing the work. This early process resembled that of the acetylene torch and is rarely used today.

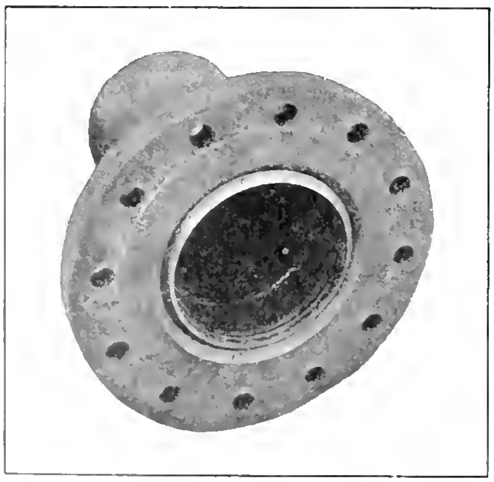

Fig. 3 Pipe End and Flange, Ready for Welding

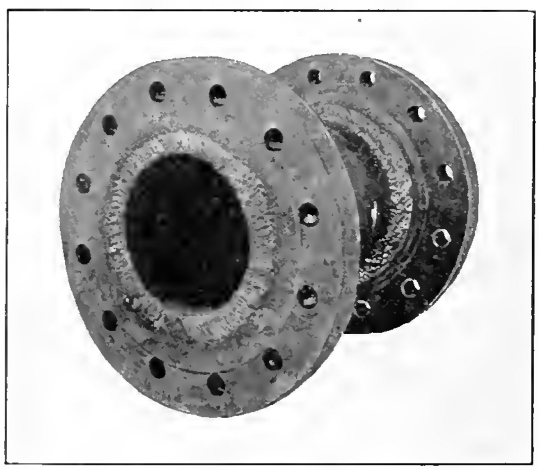

Fig. 4 Pipe and Flange with Weld Complete

The next improvement in the art was due to Bernardos, who dispensed with the electromagnet and one carbon, using instead the work as one side of the circuit and a carbon as the other. The arc was struck directly on the work, immediately producing the desired heat, and at the same time the welding wire was fed into the work. This process is still extensively used and lends itself most advantageously to many phases of modern practice. It is generally referred to as carbon welding.

A further development was made by Slavianoff who introduced the method of using the welding wire for both striking the arc and feeding it into the work. As a result the welding wire became known as the electrode, and the process as metal-electrode welding. It is one of the most generally used today and whenever discussing it the term "electrode" refers to the metal added in the operation and the term "parent metal" to the metal to be welded. In recent years the term "arc welding" has been understood to mean metal-electrode welding, and it is generally customary to qualify the phrase when referring to carbon welding.

In the past a great many failures of welds have been largely due to the operator, who did not manipulate the electrode so as to bring the parent metal to a molten state. This resulted in the electrode being deposited on but not uniting with the parent metal, since no pressure is added to complete the union.

As an example of one such failure, the following may be of interest. A short time ago the writer was connected with ar enterprise where difficulty had been experienced in successfully expanding 6-in. extra heavy pipe into steel flanges. Fig. 1 show a section through a flange, with the pipe in place before an after expanding.

This method, however, proved unsatisfactory. Both th screwed flange and the Van Stone or flanged joint had also bee

Abstract of a paper presented at a meeting of the San Francisco Section of The American Society of Mechanical Engineers, February 13, 1919.

[1] Electric Inspector, U. S. Shipping Board

disapproved, and when arc welding was suggested the writer was asked to make a sample for test.

Fig. 2 shows the welding required and Fig. 3 the pipe with one flange in place and the end of pipe beveled to form half the V for the arc-welding operation, the other half of the V being formed by the original bevel provided on the flange for the intended expanding process. Fig. 4 shows the welding operation completed. It will be noticed that the operator has overfilled

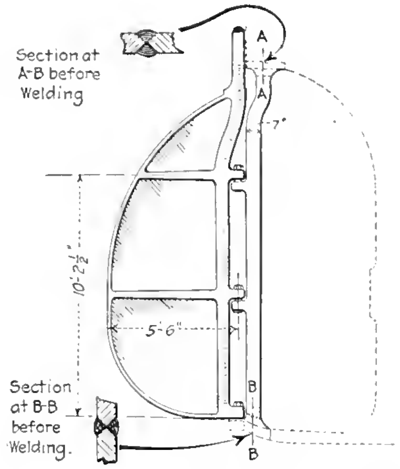

Fig. 5 Rudder Post Repaired by Welding

the V on the face of the flange, thus making it necessary to machine the fitting.

It is still generally believed that the metal in passing through the arc loses all its ductility and elasticity and assumes characteristics wholly those of cast iron or steel. The turnings of this weld, however, presented an appearance similar to good machine steel, and when analyzed showed the following: Silicon, a trace; sulphur, 0.075; manganese, 0.23; phosphorus, 0.0018; carbon, 0.25.

While it was essential that this weld be able to stand a steam pressure of 200 lb., the sample was tested first at 500 lb., then at 800 lb., next at 1000 lb., and finally the pressure allowed to go the available limit of 1400 lb.

This test was witnessed by a number of interested parties, but one skeptical member asked that the specimen be given a hammer blow with the full pressure on. This was readily agreed to, and, since the workmen refused to strike the blow, the writer secured a 14-lb. hammer and struck twelve blows on the face of the flange, after which examination was made and no damage whatsoever was apparent. Six blows in the reverse direction were also given without producing any failure of the weld.

Fig. 6 Engine Frame in Course of Repair by Welding

The weld was then tested. It was believed the weld was not more than 25 per cent efficient, for the operator had not given his best efforts to the work, and as the welding material was only of about 50,000 lb. tensile strength the effective area of welded material would probably show about 250,000 lb. This, however, was greater than the strength of the twelve ¾-in. flange bolts, which was perhaps 150,000 lb. The weld was then pulled in an ordinary testing machine at 119,000 lb.

Although the test had proved the weld capable of sustaining a strain greater than ever likely to be met in service, it was completed by breaking the weld. To do this the flanges were enlarged, and when the piece was again pulled, the weld gave way at 208,000 lb., but before this the flange on each end had dished about ½ in.

The results of these tests, while showing that such a weld might be serviceable, nevertheless justify the statement that the weld was a failure, for the broken specimen showed that only about 1/5 of the welded material united with the pipe and flange. This was most apparent from the specimen itself, which thus justified the previous estimate, since 208,000 lb. is practically 20 per cent of the amount which it was assumed the weld would hold when figuring the 25 per cent weld at 250,000 lb.

In passing, it is of interest to note that in one of the large manufacturing plants near Philadelphia, Pa., there is a 2000-lb. hydraulic pipe system installed, every joint of which is arc-

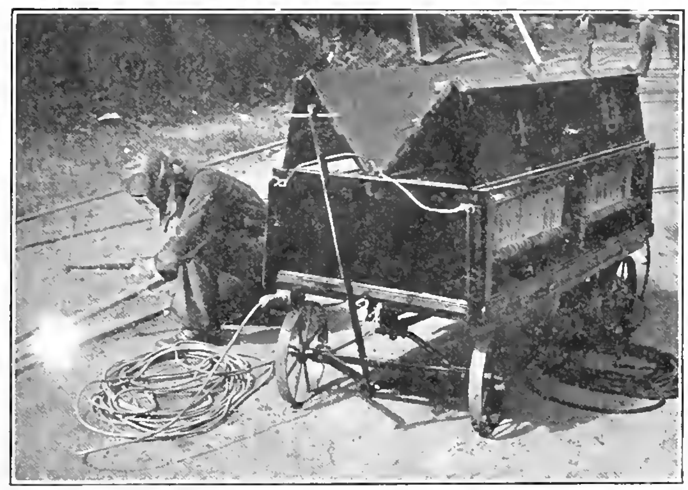

Fig. 7 550-Volt Railway Arc-Welding Set

welded, and although it has been in service a year and a half no joint has developed a leak or given any trouble. There are a number of firms today who are using electric arc welding for securing flanges to pipes and making T and other connections on steam lines, and their excellent records testify to the ability of arc welding to withstand the many strains of time and service.

Many other examples could be presented. The following is one of particular interest, as it shows the service to be expected under severe conditions.

On the large 16-wheel articulated locomotive it is necessary to have a ball joint in the steam pipe between the two trucks, and one manufacturer has, for about six years, used the arc welding process to fasten in place the ball of this joint. This weld must stand vibration from the jar of the locomotive over track and joints, tension and compression from the forward and backward movement of the train, reverse strain as the curves from right to left are made, and an internal steam pressure of about 100 lb. Six years' service has brought no reports of failure.

As an illustration of the saving in time and money often resulting from arc welding, the following incidents are typical. The Italian ship *Titania* had a badly damaged rudder, but it was successfully repaired by arc welding at a saving of $10,000 and 4 months 2 weeks of time. One part of the weld was completely through the 6-in. by 9-in. rudder post. This vessel was repaired in August 1916 and has since seen constant service.

Another case of a broken rudder successfully repaired is

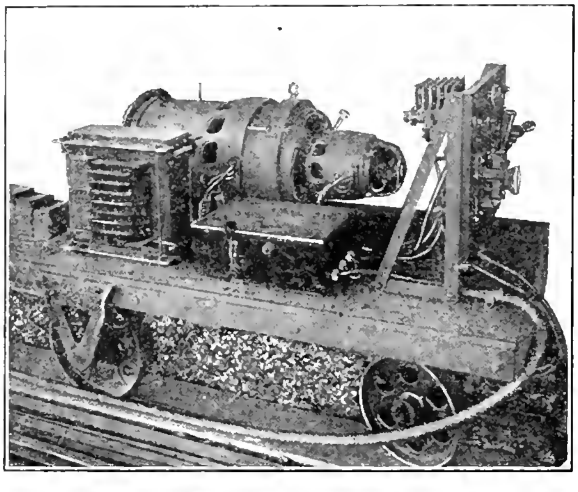

FIG. 8 PORTABLE MOTOR-GENERATOR ARC-WELDING SET

shown in Fig. 5. Here the rudder post was welded into place, the sketch clearly showing the operation. This work was done in May 1916, and if installed in the usual manner would have occasioned a delay of at least 6 months, with the necessity of using a dry dock. Instead, arc welding saved 10 per cent in cost and restored the vessel to service 5 months sooner.

An illustration of the use of arc welding in railroad practice is shown in Fig. 6. This is an engine frame broken at a place most inconvenient to weld. In this case, however, the repairs are being made with the frame still in place. Notice the V groove filled by arc welding, also the ingenious method used by the operator to obtain the desired fillet. He has used the half of an old brass lining to which the welding material will not readily adhere.

A report of the electrical engineer of one of the great middle-western railroad systems accredits to arc welding a saving of about $200,000 in one year. This saving was computed from economy in this method over others previously used on the same class of work, and also from the saving effected by the restoration to service of otherwise useless apparatus. Since that report this road has increased its number of welding units about 300 per cent.

Developments in welding equipment are shown in Figs. 7 and 8. Fig. 7 is a resistance grid for use on a 550-volt railway circuit, and it is a type in present-day service. For welding with a ¼-in. electrode it requires an approximate imput of 200 amperes at 550 volts or 110 kw. to produce 200 amperes at about 18 volts or 3.6 kw. at the weld, resulting in a total loss in wasted energy of 106.4 kw.

This type of apparatus is chiefly used for street-railway work, and the process has proved so successful that even the high cost of wasted electrical energy has failed to eliminate it as a most profitable and satisfactory investment.

A motor-generator of the type shown in Fig. 8 would accomplish the same result with an input of 6 kw., or 11 amperes at 550 volts. The weight of this unit and portable truck is about 1800 lb.

Among the great lessons which the recent war has taught us are economy and the conservation of our time, energy and raw material, and arc welding presents a veritable storehouse of opportunities ready for the engineer who will adapt them to his own requirements.

In the course of the discussion which followed Mr. Anderson's paper the following interesting facts were brought out. Since 1906, the Pelton Water Wheel Co. has used arc welding for very heavy work, in building up large steel castings. In making these castings the shrinkage stresses are so severe that the reinforcing ribs are often pulled apart and ruined. The reinforcing ribs are therefore cut to allow for this shrinkage and then welded.

In discussing the relative merits of alternating and direct current the consensus of opinion seemed to be that direct current is the more suitable for arc welding. Alternating current can of course be used, but it takes a more experienced man to maintain the arc, and in practice there are very few that are able to weld with any degree of satisfaction.

In discussing the question, What, in general, is the effect of the weld on the character of the metal? it was brought out that metallurgists and chemists are trying to arrive at some standard for electrodes. It must be remembered, however, that the parent metal has certain constituents that become molten. The electrode also becomes molten and it has certain constituents. These two commingle and form other elements which disappear in the heat of the arc, are carried off in the oxide, and sometimes, strange to say, form a new composition. The advocates of the covered electrodes claim one thing, others use fluxes, and still others metals in various proportions, and every one is claiming certain results for the particular method he uses.

Classical Education for Engineers

Dean Mortimer E. Cooley, in two articles published by the *Evening Sun* of New York, April 14 and 15, advocates the broadening of engineering courses by teaching young engineers three or four years of Latin and Greek, some political economy, considerable history, philosophy, a good knowledge of English and a speaking knowledge of at least one foreign language, preferably Spanish. He said that "the one great need today from our educational institutions is training for responsible citizenship" and rather than give our youth "a smattering of this and that so-called practical thing as a preparation for college" it were better to prepare them "to be of maximum use to themselves and their fellowmen."

The study of Latin and Greek, Dean Cooley remarked, sets forth before the mind the civilization and wars of early times and the characteristics of the people who developed that degree of culture which even in this time of tremendous achievements surprises us for its advancement.

He further emphasized the necessity for broadening the technical man by citing "the relation of the engineer, in the different branches of his science, to the worker . . . who typifies the constructive half of our civilization known as 'Labor,' and his equal and important intimacy with the other, the provisioning and directing half, usually termed 'Capital.'" Thus it is that the engineer being the connecting link between capital and labor, "there is one phase of the engineering profession . . . which is of even broader value to the nation than that of material advancement." And yet in spite of the "need of engineering skill in the direction of executive matters of state and national problems," engineers are unwilling to enter political life, precisely because "our technical institutions are specializing too much" and "vision, background, knowledge of life and the 'humanities' suffer at the expense of an almost selfish concentration on laboratory methods."

A new system is being set up in the world, continued Dean Cooley, and "our international leadership in industry, commerce and political idealism demands superior training for the young men who are to continue the administration of our affairs," because "no longer is government simply the administration of a system of statutes, the collection of taxes and duties and the maintenance of a military system," but "it is a complicated machine by which the citizens themselves drive forward the great industrial, social, commercial, aesthetic and idealistic entity of the State." And so it is that "our future engineers should stand head and shoulders above the present professional man of today to fulfill their full duties to the nation and to themselves as citizens."

Dean Cooley concluded with an exposition of the forces which inevitably led the German military machine to its complete destruction. The German war diplomacy "could not grasp the psychology and spirit of other peoples" and "the specialist . . . without his schedule, prepared and learned by rote, was nonplussed and conquered when his carefully built plan went wrong and found unexpected obstacles."

Relative Corrosion of Wrought-Iron and Steel Pipe

AT the last Annual Meeting of this Society a paper was presented by Dr. William P. Gerhard of New York on the Relative Corrosion of Cast Iron, Wrought Iron and Steel Pipe in House Drainage Systems. The paper was based on the examination of the pipe-drainage systems in 78 tall buildings of New York City along the line of Broadway, beginning at Bowling Green and ending at Forty-second Street, a distance of approximately four miles. Numerous illustrations were given, taken from photographs of roof pipes which had corroded, in order to illustrate the effect of corrosion and to show its relative effect on different kinds of material.

There were also tables in which were tabulated in very complete form the data relative to the various installations and with respect to the observed conditions. Dr. Gerhard's conclusions with regard to welded steel pipe and welded genuine wrought iron pipe, a report upon which constituted the main part of his paper, were as follows:

Welded Steel Pipe. The investigation showed conclusively that *steel pipe* is *much inferior* to both *cast-iron* and *wrought-iron pipe* when exposed to corrosive action. In many cases the black steel vents showed scaling to a considerable depth after only ten years' use. Generally speaking, galvanizing was observed to be somewhat less of a protection against corrosion on steel pipes than on wrought-iron pipes. It appears that the galvanized coating does not adhere so firmly to the smooth surface of steel pipes as to the comparatively rougher surface of wrought-iron pipes. The galvanizing on steel pipes showed signs of disappearing within 10 to 20 years, after which time the life of such pipe may be assumed to be merely equal to that of ordinary black steel pipe.

Welded Genuine Wrought-Iron Pipe. The investigation has furnished an almost overwhelming evidence *in favor of genuine wrought-iron pipe* and *against steel.* To mention only one example, contrast the black wrought-iron vent pipes of the Mail and Express Building, installed 27 years ago, with the black steel vents in the Townsend Building, put in 22 years ago. It was also found that the galvanized coating lasts a little longer on the wrought-iron than on the steel pipes, but that ultimately the rust resistance of the base metal is of far greater importance than that of the coating.

Conclusions were also drawn with regard to the use and durability of cast-iron pipe having calked joints and screw-jointed pipe systems. Concerning these, it is stated that while it is freely admitted that cast-iron pipe, as such, is a satisfactory material for house-drainage purposes, and that many of the cast-iron roof vents inspected showed a much better condition as regards corrosion than anticipated, the objections to a cast-iron system, well-known heretofore and corroborated by this investigation, are the unsafety and unreliability of the calked joint. A calked joint can never be considered a permanent one as long as expansion and contraction cannot be eliminated.

An abstract of the paper was published in The Journal of the Society for November 1918, and the paper in complete form has been issued as a pamphlet.[1]

The discussion upon this paper was extended, and the account which follows is in abstracted form with duplicate matter omitted and the whole condensed in so far as possible without changing the intent of the writers.

Discussion

GEORGE SCHUHMANN. The discussion of the relative corrosion of wrought iron and steel started about twelve years ago, and to those who have kept informed on the subject the question has undoubtedly been decided in favor of wrought iron when used under ordinary working conditions. Unfortunately, the matter has been much befogged by the investigations of many experimenters who have based their conclusions on so-called accelerated corrosion tests such as acid tests, etc.

I made the same error a number of years ago after some steel pipe had been in use for a few years and the practical evidence pointed in the direction of a more rapid corrosion of steel pipe than of wrought-iron pipe. I found, by testing with diluted sulphuric acid, that while the steel pipe had been somewhat reduced in thickness, the immersed portion of the wrought-iron pipe had been completely ruined. Many other similar experiments were tried with practically the same results; but as the evidence of both wrought-iron and steel pipes that had been in use many years showed decidedly in the opposite direction, it led to further investigations in relation to the structure of the metal itself.

Chemical analysis did not lead to any practical results, as there is really not much difference between the chemical composition of wrought iron and low-carbon steel. There is, however, a decided difference in their physical structures, due to the great difference in their methods of manufacture.

The temperature in the puddling furnace in which pig iron is converted into wrought iron is about 2300 deg. fahr., not enough to melt wrought iron. After the pig iron is melted, the stirring up of the molten mass under the influence of the flame and the material composing the lining of the furnace causes the pure iron to separate from the impurities and solidify because the temperature of the furnace is not high enough to keep the purified iron liquid. The carbon in the pig iron is burned out and the other impurities form a liquid cinder in which the pure-iron globules float around like sugar crystals in molasses in a vacuum pan. When this spongy mass is removed from the furnace and compressed by squeezing, hammering and rolling, much of this fluid cinder is expelled, but a thin coating of each globule remains, and when the mass is rolled out the iron fibers become coated with minute capsules of cinder. This cinder consists principally of silicate of iron, and because silicate of iron resists ordinary corrosion much better than pure iron, the presence of the silicate in wrought iron causes it to resist corrosion better than steel.

Steel, on the other hand, is made at a much higher temperature, which keeps the whole mass liquid, and the cinder generally floats to the top, where it is removed. After the steel melter has finished his work the metal is still in a liquid state—too hot for rolling—and it must be allowed to cool, during which process soft impurities which remain flock together in a liquid mass by what is technically known as "segregation."

While silicate of iron resists corrosion due to ordinary exposure much better than pure iron, it readily dissolves in a strong acid, which explains the results obtained by means of the accelerated corrosion tests. Further evidence that cinder or slag with which wrought iron is impregnated affords resistance against slow corrosion has been demonstrated by observations upon the durability of sheet-iron roofing reported by Mr. R. C. McBride, of Youngstown, Ohio.[1]

Another important factor to which I will call attention is that corrosion acts very capriciously, sometimes concentrating itself on certain spots (pitting), while at other times and under apparently the same conditions it will diffuse itself over larger areas. Several years ago, in the Indiana gas belt, two parallel pipe lines were taken up on account of the gas giving out. Each line was 25 miles long, and the two lines had been laid side by side in practically the same soil and had transported the same kind of gas. The wrought-iron pipe was 8 in. in diameter and had been in service 18 years, while the steel pipe was 6 in. in diameter and had been in service only 11 years. While 24¾ miles (over 99 per cent) of the wrought-iron pipe was still in good condition after being taken up, 1200 ft. (nearly 1 per cent) was corroded so as to make it unfit for further use. On the other hand, 14 miles (56 per cent) of the steel pipe was thrown aside for the above reason, 11 miles, or 44 per cent, being still in good condition.

WM. W. WALKER[2] expressed the opinion that the author's investigation was too fragmentary to warrant his broad generaliza-

[1] The Relative Corrosion of Cast-Iron, Wrought-Iron and Steel Pipe in House-Drainage Systems, Wm. Paul Gerhard. Price, 15 cents to members, 30 cents to non-members.

[1] Corrosion Tests, *Engineering Record*, May 20, 1911.

[2] Professor of Chemical Engineering, Mass. Inst. of Technology, Cambridge, Mass.

tion as to the superiority of genuine wrought-iron pipe over steel pipe. He further said:

In Par. 48 the author speaks of his investigation as having afforded . . . "an excellent comparison of the life of wrought-iron and steel pipe under equal conditions to service." . . . Inasmuch as in no single case were samples of wrought iron and steel taken from the same continuous structure, I can state from my experience that the conditions of comparison were very inadequate and the results can be entirely misleading. The factors which control speed of corrosion are so many and so difficult of determination that unless two pieces of metal have been subjected to *identically the same conditions* a comparison as to durability is worthless.

The broad statement that genuine wrought-iron pipe "has shown itself in actual service and under a variety of conditions. . . to be much more resistant to corrosion than steel pipe," I must most emphatically deny. I can state with conviction that whether the wrought iron outlasts the steel, or the steel outlasts the wrought iron, depends upon whether one is dealing with good steel and poor wrought iron, or good wrought iron and poor steel.

JOHN L. ROBBINS[1]. The author's conclusion that genuine wrought-iron pipe is far more durable than steel pipe for house drainage purposes does not seem to me to be proved at all. Most of the tests, the results of which showed the wrought-iron pipe to be in better condition than the steel, were made on piping which was installed when wrought-iron pipe was at its best and steel pipe was at its worst. The author's conclusions are based on the inference that the pipe of today is of the same standard as that used in most of his tests, and make no reference to the great improvement in the steel pipe of recent years. In buildings erected eight or nine years ago, such as the Fifth Avenue Building and the Martine, the steel pipe in the author's tables shows up as "as apparently good," or as "good as new."

A. E. HANSEN[2] devoted considerable attention to a discussion of the merits of the screw-pipe system of wrought iron or steel pipe, and of the use of cast-iron pipe with lead-calked joints for drainage and vent pipes.

Much controversy has existed among engineers about the relative value of cast iron compared to wrought iron or steel pipe in house-drainage systems, but it has been heretofore generally conceded, and Dr. Gerhard also concludes that the life of extra heavy cast-iron soil pipe is fully as great as that of genuine wrought-iron pipe. Mr. Hansen's own observation was that the life of cast-iron pipe for drainage systems has been proved for about 60 to 70 years, whereas proof exists that wrought iron has outlived a period of but 30 to 35 years in drainage systems. The criticisms against the use of cast-iron pipe consist of the alleged weakness of lead-calked joints; the possible existence of sand or blow holes; and the greater number of joints required.

He said that while the weakness of the calked joints as pointed out by the author is true to some extent, the very fact of possible expansion and contraction of cast-iron soil-pipe systems at their leaded joints is a distinct advantage, especially in tall buildings.

One of the chief objections to the use of screw pipes is the combination of screw pipe with galvanized cast-iron fittings. The galvanizing hides serious defects and the fittings are easily cracked by the expansion and contraction of the rigidly connected screw pipes. He considered other objections to be a reduction of the thickness of the metal at the threaded ends; the peeling off of the galvanizing at the ends where the threads are cut; the difficulty of making repairs; the use of steel-pipe nipples which, if it is admitted that steel pipe itself is unsatisfactory, are still less desirable because of the cutting away of the metal in threading; and obstruction to flow in the pipes due to neglect on the part of the workman in reaming the ends or in allowing red lead to enter the pipe when making the joints, where it hardens.

As to the question of the higher cost of completed wrought-iron drainage systems over completed extra heavy cast-iron soil pipe, the author secured comparative estimates of cost of a genuine wrought-iron galvanized Byers pipe stack, 100 ft. long, with a galvanized cast-iron drainage branch fitting every 10 ft., and a similar extra heavy cast-iron soil-pipe stack. The quotations furnished cover stacks, 2 in., 3 in., 4 in., 5 in. and 6 in. in diameter. The excess cost of galvanized wrought-iron stacks is as follows:

Stack diam., in.	2	3	4	5	6
Excess cost, per cent:					
W. G. Cornell & Co.	0	25	55	70	85
Lasette & Murphy	23	65	74	97	119

Referring specifically to the question of corrosion in the discussion in the author's paper, Mr. Hansen said:

"I believe that the opinion of engineers who are competent to judge, favors the use of wrought iron for plumbing water-supply pipes even though its cost is somewhat in excess of steel pipe."

Engineers, architects and contractors have frequently questioned the wisdom of using genuine wrought-iron pipe because of this additional expense. No specific proof had been brought which would warrant them in spending their clients' money in this manner. It is of the greatest interest, therefore, to find that Dr. Gerhard draws the conclusion from his investigations covering an inspection of the pipe drainage systems in 78 tall buildings, that genuine wrought-iron pipe is far more durable for house-drainage purposes than a steel pipe. A careful study of his detailed report indicates that this conclusion is correct.

It should be understood, however, that the author's investigation did not cover main and branch vent pipes in the building, which, of course, are difficult of access. Roof vents are exposed to the corrosive action of both the atmosphere and rain water, and the oxidizing agents which they contain, as well as to the corrosive influences of the sewer air.

W. H. KENERSON.[1] The paper is interesting because of the very definite conclusion reached as a result of the author's investigations. For a great many years I have followed the discussion of this subject with much interest and have made many investigations myself but without being able to arrive at any such positive conclusion as the author. Prior to ten or fifteen years ago, before steel pipe was made as well as it is today, it was rather easy to find many examples where wrought iron was distinctly superior to steel, but of late years this condition has changed. Evidence collected at random is so very contradictory that it would not be at all difficult, by properly choosing data, to "prove" that either wrought iron is superior to steel or that steel is superior to wrought iron, whichever seems desirable for the moment.

Sometime ago I was asked by the National Tube Company to secure various kinds of iron and steel pipe and determine their relative corrosion in a hot-water line in one of the dormitories at the University. I installed two series of pipes of identical size and length, including genuine wrought iron, black "wrought," black copper alloy, galvanized "wrought," and galvanized copper alloy. After about a year of use all of the pieces were in such poor condition that they were practically useless. No very great difference existed between them. The tests indicated the slight superiority of the black "wrought" or steel pipe over the others, but it might not be unlikely that another similar series of tests would reverse the conclusion.

For many years I investigated personally, or caused to be investigated, the relative corrosion of pipe lines of various kinds, and it is my experience that with modern steel pipe and well-made wrought-iron pipe there is very little if any difference in behavior under corrosive influence. One of the most convincing evidences to me is the fact that while practically all pipe lines, both steel and iron, include wrought-iron couplings, I never have seen myself nor has anybody reported to me any difference in the condition of the couplings and pipe in any given line. I have found many individual cases where wrought iron appeared superior to steel, and many cases where the reverse is true. I am inclined to believe that Mr. Gerhard's positive "proof" of superiority of wrought iron over steel may hold for the cases he instances, but is not completely convincing as a general proof.

J. O. HANDY.[1] The author's investigation, to have been conclusive, should have included every precaution to avoid errors in distinguishing wrought iron from steel. A qualitative test for manganese, such as was used, is not sufficient to distinguish between wrought iron and steel, particularly when the amount of metal used varies to an unknown degree. The manganese content of wrought iron is known to be very variable, and that in steel of the kind used for pipe is by no means constant.

In our own practice, we do not consider that we have proved pipe to be steel or iron until we have determined carbon, manganese and silicon *quantitatively*, and also made a microscopic examination.

A second source of error was not taken into account by the author, viz., that small percentages of copper, such as are sometimes found in wrought iron, cause it to be very resistant to corrosion by atmospheric influences. Extended tests have shown that wrought iron free from copper is no more durable than steel. On the other hand, when both the wrought iron and steel contain the same amount of copper, they are equally durable.

I have personally taken part in a number of very thorough tests of wrought-iron and steel pipe under the most severe service conditions in hot-water systems. For the purpose of securing results in a shorter time, ungalvanized wrought-iron pipes were purchased in the open market, cut to the same lengths, and exposed in the same hot-water line with steel pipes. After 14 months the line was taken down and it was found that the pitting of the wrought-iron pipe and of the steel pipe had been equally deep and extensive. The amount of roll scale adhering to the pipe was the controlling factor in determining the degree of pitting. Steel pipe free from scale did not pit, and the corrosion in general was much less. A detailed report of Part 1 of the corrosion test of steel pipe to which I have just alluded may be found in the Journal of the American Society of Heating and Ventilating Engineers, page 159, volume for 1917. The tests showed that genuine wrought-iron pipe of the two best-known brands was no more durable than steel pipe having the usual roll-scale covering. On the other hand, steel pipe freed from scale by a special process of rolling was far more durable than either of the kinds of pipe just mentioned.

Bearing on the relative durability of steel and iron containing small percentages of copper are the following references:

D. M. Buck: Keystone Copper Bearing Steel. A Discussion on Corrosion, July 1914. (Jl. Am. Iron & Steel Inst., May, 1915.)

D. M. Buck and J. O. Handy: Research on the Corrosion Resistance of Copper Steel. (Jl. Ind. & Eng. Chem., 1916, p. 200.)

The author's conclusions, which are based on insufficient evidence as to the composition of drainage pipe which failed, are not convincing to one who has taken part in scientifically conducted researches in the corrosion field. His observations upon vent pipe also are not dependable, because the identity and composition of the pipes were not established beyond question.

[Mr. Handy transmitted with his discussion a copy of a report upon tests made by the Pittsburgh Testing Laboratory to determine the comparative resistance to corrosion of wrought-iron and steel pipe when used in a system supplying hot water to shower baths. The tests were made upon ungalvanized pipe in a hot-water system during a period of 14 months. No significant differences were discovered in the depth or extent of the pitting as between the steel or wrought-iron pipe. Both had corroded rapidly. The main factor in its influence upon corrosion appeared to be the roll scale. Where this was removed by mechanical processes the rate of corrosion was diminished to about 20 per cent of the rate for pipes carrying the usual covering of roll scale. Inasmuch as Dr. Gerhard specifically states in his paper that his "investigation was restricted to the drainage and vent system, and the hot- and cold-water pipes were excluded from consideration," the report will not be given here in detail.—EDITOR.]

F. N. SPELLER.[2] The author's statement that "Steel pipe is vastly inferior to genuine wrought iron pipe" is based, as he says, on inspection of roof vents, the relative condition of the drains (the important part) being mainly based on the assumption:

1. That all vents examined were subject to the same kind of service.
2. That his observations of corrosion in vents were representative of wrought iron and steel as a class and that the same conditions of corrosion prevailed in the drains as in the vents.
3. That material in the drain pipe which failed is the same as the vents or other pipes in the system.

No evidence is given to warrant the first of these assumptions, but granting this for the present, the investigation on the vents is interesting only as a comparison of metals under atmospheric corrosion—the air evidently being the most important factor, as the corrosion of these vents is always more pronounced near the top.

The results would be more valuable if the method of identification had been more conclusive and had the copper and other elements been determined. Those who have gone into this subject are now almost unanimously agreed that in atmospheric corrosion certain elements, particularly copper, have a controlling influence regardless of whether iron is made in a puddling furnace or in the bessemer converter. Some steels are so low in manganese as to pass as wrought iron under the rough qualitative test used in this investigation unless fracture or etching tests are also applied. Several references are given below, containing general information on the influence of copper in iron under atmospheric corrosion.[1]

It has been proved by tests in service to destruction that 0.1 per cent to 0.3 per cent copper (or even less) has a very marked effect in prolonging the life of iron in air, so much so that bessemer copper steel has been found to be practically as good as new after reworked wrought iron and ordinary steel had been entirely destroyed.[2]

"As further evidence of the influence of copper content, we have lately taken down some tests which were started seven years ago with a view to determining the effect of small additions of copper to pipe steel exposed to impure air. The results are shown in Fig. 1. After some consideration it seems that this should offer a solution and a remedy for the trouble experienced with vent lines and drains, although it should be understood that it is not suggested as a remedy for corrosion in water pipes and under other conditions as the copper does not seem to have much influence except under gaseous corrosion. We have found that iron pipe is protected by a small percentage of copper steel, so that it is quite probable that if Dr. Gerhard had made a complete analysis of the iron pipe and determined the copper he would have found a relation between the copper content and the corrosion.

"The sulphur and silicon contents should also be considered, so that one should be careful in concluding from the data presented in the paper that vent lines of wrought iron are necessarily superior to steel. Moreover, the size and thickness of these vents are not given nor how each one is used. Condensation in the upper portion above the roof is obviously responsible for the greater corrosion of these vents near the top and this would depend largely on what kind of fixture the vent is attached to. Also, no information is given as to the relative corrosion inside and outside nor how often these vents were painted."

"As direct evidence on genuine wrought iron and steel under severe atmospheric corrosion, the following is submitted:

"Portions of a pipe fence on a river wall at McKeesport, Pa., were constructed alternately of 2-in. black wrought-iron (puddled without steel scrap) and bessemer-steel pipe. This was erected October, 1906, and removed August, 1917, after nearly eleven years. The arrangement of test, condition of the wrought iron and steel and analyses of pipe are shown in Fig. 2 and in Table 1 which follow. The depth of pitting and general condition

was practically the same on both materials when the fence was removed. Some pieces of each material had corroded through at the posts. It will be noticed that the worst corrosion on the steel is in the bottom row, as would be expected. The bottom row of wrought iron, however, does not show this increase, probably due to the copper contents. This fence was given one coat of black paint after erection, with no further attention."

In the course of his discussion Mr. Speller called attention to a number of the author's comments which he contended were inconclusive or misleading. One of these, typical of three or four others, states that two main drainage lines in the Home Life

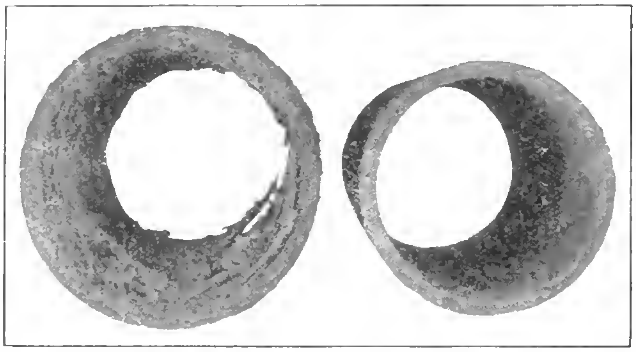

Fig. 1 Corrosion of Steel Pipe Exposed to Moist Mill Atmosphere for Seven Years. First View, Pipe without Copper Content; Second View, Pipe with Copper Content

Building failed after 25 years and that "*these were probably steel because other lines in the cellar were tested and found to be steel.*" He considered such evidence to be inconclusive, particularly in view of the fact that nearly all piping in buildings constructed during the past 30 years has consisted of mixed steel and wrought-iron construction, as confirmed by the author's investigations. Another objection, he said, is that "*relative* corrosion varies with conditions especially as between gases and liquids, so that any conclusion as to corrosion in the drains should be based on a direct

[4] Analyses of iron pipe below all showed a trace of carbon.

"Of course it would have been more desirable had there been more evidence of this kind and especially from more pipe from the drains of the same buildings. However, the data given certainly do not support the author's conclusion as to the inferiority of steel pipe for drains, but on the contrary indicate surprisingly little trouble, and what there is, according to the data, is at least equally divided between wrought iron and steel.

"Most of the steel pipe included in this report was made over 10 years ago before 'Full weight' became standard, and before improvements in the manufacture of modern steel pipe had been developed and put into practice. Much of the drain and vent pipe in use at that time was light merchant weight with no protective coating."

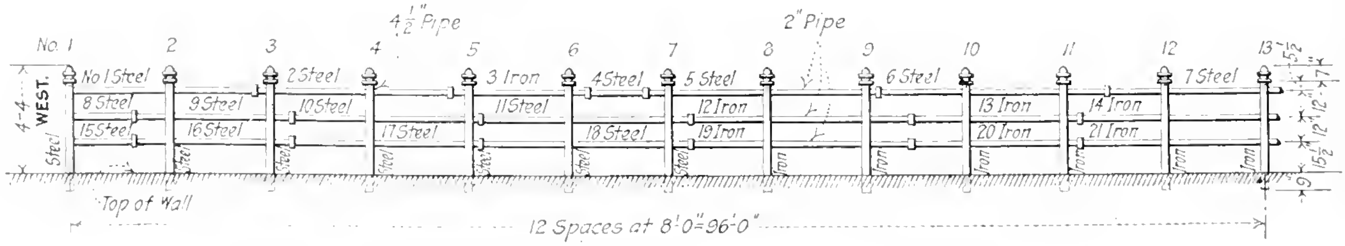

Fig. 2 Harbor Wall Pipe Fence Subjected to Corrosive Action for Eleven Years

examination of these drain pipes and not by assumption and inference from material exposed mainly to atmospheric corrosion.

"However, taking all the results of examination of drainage pipes, as reported in Table 1, as the basis of comparison, but eliminating such cases as No. 58 where the house drains are reported as 'Wrought iron; could not inspect; no trouble,' as incompetent and immaterial, and including in the first place only those buildings where the author was able to examine the pipe which had failed or where there had been no trouble, and it had been possible to make tests on the drains, we find from the author's notes, Table 1:

Pipe material and service given, as reported in Table 1	Investigation in which replaced pipe was examined and tested or where no trouble had been experienced with drains, the kind of pipe determined from tests on drains.		Including additional cases where the kind of pipe is inferred from examination of other pipe in building.

	Total	19	Final total	29

Note.—Nos. 58 and 61, in which report apparently favors wrought iron, and 62 and 70, apparently favoring steel, were left out for lack of any evidence as to material involved.

James Aston, in comment on the four references given by Mr. Speller, and as joint author of one of them (Burgess and Aston), sent the following analysis of these investigations:

The work of Burgess and Aston covered tests upon small samples only, and was not a test to destruction but solely upon the weight lost in a one-year interval. Again, it did not refer to comparative tests of steel and wrought iron but dealt entirely with the influence of different alloying ingredients upon the corrosion loss in the atmosphere; among these was copper-bearing material. Wrought iron played no part in the test or in the discussion of results.

The paper of Storey covered an examination of old barbed-wire fence, and he noted that where the steel wire was in good condition it carried copper, whereas wires which had been destroyed were free from copper. While practically all of the samples were steel, it is significant that there were a few wrought-iron samples; these were in as good condition as the copper-bearing steel and they contained no copper.

The tests of the American Society for Testing Materials deal with sheets exposed to the weather. Among these are all classes of steel and some wrought iron sheets with and without copper. While some of the steel sheets, especially bessemer steel, have failed, the tests have not progressed far enough to be conclusive,

particularly with regard to the relative durability of wrought iron and copper-bearing steel.

The paper of Buck and Handy cites only steel and ingot iron products, the tests including full-size sheets exposed to the weather, and accompanying exposure of small samples 2 in. by 4 in. in size for record of loss of weight. No mention is made of wrought iron.

Author's Closure

Mr. Hansen refers in his discussion to the question of the relative merits of steel and genuine wrought iron pipes for water supply lines. As this is a subject by itself, which was not involved in the author's investigation, no reference need be made here. But further on Mr. Hansen agrees with the author "beyond the shadow of a doubt" that for house drainage purposes genuine wrought-iron pipes are far more durable than steel pipes.

The question raised, as to whether atmosphere and rainwater or the sewer air produced the larger percentage of corrosion, appears to the author to be one of small significance in view of the fact that *all* vent pipes examined and tested were subject to identical conditions of service, regardless of whether they were of steel, wrought iron, or cast iron.

As regards cast iron pipe, Mr. Hansen concedes the weakness of the calked joint, which was the principal point brought up by the author against the use of cast iron in house drainage.

As to the higher cost of screw-jointed pipe systems, this is, to some extent, conceded, especially for small installations. In large installations, however (both in tall buildings and in extensive groups of low buildings), contracting firms equipped with the required pipe-cutting machinery have frequently made but a slight difference, and sometimes none at all, between the cost of a cast-iron calked and a welded screw-joint pipe system. I prefer disregarding the comparative estimates of cost submitted by Mr. Hansen, which I understand to be recent figures, and not figures based upon "pre-war" conditions. Prices of material and cost of labor or both, at the present time are factors of considerable uncertainty, and no definite or important conclusions should be based on them.

Mr. Schuhmann maintains that the question of relative corrosion of wrought iron and steel pipe has "undoubtedly been decided in favor of wrought iron pipe, when used under ordinary working conditions." The author's investigation was based solely upon roof vents in use under ordinary or normal conditions, and no accelerated corrosion tests were considered.

In preparing his paper, the author was not unaware of the fact given by Mr. Schuhmann that some of the discussions before the American Society for Testing Materials, and many experiments made by individuals, confirm the superiority of wrought-iron pipe.

In reply to Professor Walker's statements, it is to be regretted that he could not bring himself to look upon the author's investigation as more than a "fragmentary" investigation and "a statement based upon inadequate data." Professor Walker indicates his belief that there is practically no difference in the corrosion of steel and wrought iron; the author is convinced, nevertheless, that if he had had Professor Walker's assistance or company in his examination of these numerous New York roof vents, he could hardly have escaped changing his opinion.

It would be useless to try to refute Professor Walker's assertion that the data gathered were "inadequate."

Professor Walker is obviously in error when he says that "in no single case were samples of wrought iron and steel taken from the same continuous structure (!)" What fairer proceeding could there be than to take samples and record conditions of corrosion from both wrought-iron and steel pipe standing alongside of each other, *on the same roof, under equal conditions, serving the same class of fixtures, and of equal length of service,* as was done at every opportunity?

In view of this, Professor Walker's contention that the conditions of service were not identical and therefore that no comparisons as to durability can be made is quite incomprehensible.

From his knowledge of the manufacture of wrought iron pipe, the author contends that Mr. Robbins is mistaken when he asserts that wrought-iron pipe made twenty or thirty years ago was a better article than it is to-day, nor does the author believe that there has been in recent years such "a great improvement in the manufacture of steel pipe" as he claims. Five years of service is apparently not a sufficient exposure to corrosive conditions for vent pipes, and for this reason, neither wrought-iron nor steel pipe of such limited age of service was taken into consideration in this investigation.

Professor Kenerson intimates that some of the data on roof vents may have been "properly chosen" to prove that wrought iron is superior to steel. The facts, however, are these: The investigation was begun at the lower end of Broadway and extended to 42d Street, taking in the buildings on both sides of the street in consecutive order, omitting only those which were of very recent date, and buildings of minor importance. In not one case, on entering the buildings and proceeding to make the examination, did the investigators know what kind of pipes they would encounter on the roofs, or in the cellars. The author neither collected his evidence "at random" nor did he aim to chose only data to prove wrought iron superior to steel.

Mr. Handy claims that the qualitative manganese test is not sufficient to distinguish between wrought iron and steel. It is distinctly stated in the paper that fracture tests were made in a number of cases; and where any doubt existed, larger samples of the pipes were submitted for further physical test and qualitative analysis to the metallurgical and chemical departments of Columbia University.

But it must be obvious that where so many hundreds of pipes were under investigation, it would have been both too expensive and too slow a process to have a complete quantitative analysis made of every single pipe. Mr. Handy is, to my knowledge, the only person broadly claiming that the so-called "manganese test" is insufficient and unreliable.

As to the claim that the "copper content" of wrought iron causes this to be very resistant to corrosion, I will refer to the tests of a harbor wall railing, introduced in the discussion by Mr. Speller. The deepest pits, according to these tests, were found in wrought iron pipe, having respectively 0.10%, 0.06% and 0.08% of copper, and where the wrought iron pipe contained no copper the deepest pits were less in extent according to this very table. The further contention that "where wrought iron and steel contain the same amount of copper they are equally durable" is in exact contradiction of what Mr. Speller shows in his table, as evidence that steel pipe without copper content is more durable than wrought-iron pipe with copper.

In Mr. Speller's discussion there are certain inconsistencies and inaccuracies to which attention should be called.

The main purpose of the writer's investigation was to find if commercial wrought-iron pipe purchased in the open market and installed in house drainage systems is superior in rust resistance to steel pipe obtained and used in the same way. Neither steel nor wrought iron pipe has ever been marketed according to their copper content, hence this and other questions as to complete analysis, brought up by Mr. Speller, are not of interest. Moreover, a careful perusal of reports and other literature on *pipe corrosion* fails to reveal the slightest mention of copper content in pipe. Assuming, however, that copper does retard corrosion, about which point metallurgists do not seem to be agreed, it seems absurd to the author to assume that all the iron pipes of this investigation contained copper, and that all the steel pipes were free from it.

Mr. Speller's arguments as to copper content in the wrought-iron pipes having a marked effect in the prolonging of the life of iron in air, are inconsistent and unconvincing, for the very table which he introduces to prove that copper content reduces liability to corrosion shows that wrought-iron pipes with copper content showed a deeper average pitting (0.053) or corrosion than those which did not contain copper (0.045). If this is quoted to prove anything at all, the author's interpretation would be that *copper-bearing wrought iron* is *inferior* to wrought iron without it.

Furthermore, it seems ridiculous to assume, as Mr. Speller apparently does, that among the hundreds of vent pipes tested, all of these of steel should happen to have been installed so as to be subject to severe corrosive conditions, whereas all the wrought

iron ones, in many cases interspersed at random, should have been so placed as to be shielded from corrosive attack.

The fact is, these hundreds of pipes inspected were all installed, practically in the same manner, in the same kind of service, in the same locality, hence the operation of the *law of averages* applies, and minor differences as to composition, original thickness, service conditions, etc., can be disregarded. It is not an *assumption*, as claimed by Mr. Speller, but a *fact* that all the roof vents examined and tested were subject to the same kind of service, for such *roof extensions of soil, waste as well as vent lines are always intended for the removal of sewer gases from the house drainage systems, and all of them without exception are subject to the corrosive action of not only sewer air, but also of the outdoor atmosphere and at times of rain water.*

Mr. Speller expresses a doubt as to the validity of the methods of identification of the pipes, contending that some steel pipe has such a low manganese content as to pass as wrought iron, whereas the author distinctly stated that in many cases the chemical tests were supplemented by fracture tests, also that in *doubtful* cases larger pipe samples were referred to the metallurgical and chemical departments of Columbia University for chemical and microscopical determination.

Mr. Speller further contends that the author's conclusions as to the drains were based on the condition of the roof vents, whereas the author distinctly stated that "the information as to corrosion of drains *is not supported by direct evidence* as in the case of the roof vents," because it was found impossible except in the few isolated cases mentioned to obtain samples of drain pipes which had been removed on account of having corroded through. Yet the fact remains that in those cases of drain failures, where information could be obtained, the evidence, even though circumstantial, pointed to the fact that the corroded pipes were of steel.

The author agrees with Mr. Speller that it would have been desirable if more evidence had been obtained from the drains of such buildings, but he found this either impossible or impracticable. It is to be hoped that when Mr. Speller continues his research on drain pipe he may have better luck.

In making a plea for the better quality of steel pipe made in recent years, Mr. Speller states that formerly the steel pipe manufacturers were in the habit of delivering light, i.e., short-weight pipe, but is not this likewise true of some of the wrought-iron pipe formerly made? And if true, wherein lies the difference?

In spite of Mr. Speller's conclusion that the condition of the steel pipes indicated "surprisingly little trouble," the author believes that one cannot carefully examine the photographs accompanying his paper without becoming strongly impressed with the great difference in the corrosion of wrought-iron and steel pipe, and without noting the fact so clearly brought out, of the *vastly better average condition* of the wrought iron pipes as compared with that of the steel pipes.

Airship Development

In 1910, the average endurance of the German rigid airship at a cruising speed was under one day, and the maximum speed about 50 miles an hour. In 1918, with the German L70 class of 2,195,000 cu. ft. capacity, the endurance at 45 miles an hour rose to 177.5 hours, and the speed to 77 miles per hour. The British R38 class, a contemporary of the German L70, has a capacity of 2,720,000 cu. ft., and an estimated cruising endurance, at 45 miles per hour, of 211 hours. In a note on the possibilities of the commercial airships, issued recently by the British Air Ministry, it is predicted that future airships will have a capacity of 10,000,000 cu. ft., a propelling apparatus of 6000 hp., and a maximum speed of 85 miles per hour. These ships would be 1000 ft. in length, 150 ft. in overall height, possess a range of 20,000 miles, and could stay aloft for three weeks without requiring refilling. The crew would consist of three officers and 26 men, and the freight capacity would be 200 tons. The cost of a 10,000,000-cu. ft. airship is estimated at between \$1,000,000 and \$1,500,000. From *Aviation*, February 1, 1919.

WORK OF THE BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation in the form of a reply is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering, The Journal of the Society, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 215-227, inclusive, as formulated at the meeting of April 1, 1919, and approved by the Council. In this report, as previously, the names of inquirers have been omitted.

Case No. 215

Inquiry: Is it permissible under the requirements of Par. 257 of the Boiler Code to remove the caulking edges of plates, butt straps and heads by burning them off by the oxy-acetylene process instead of planing, milling or chipping,

Reply: Removing the calking edges of plates, butt straps and heads by the oxy-acetylene burning process will not be in compliance with the intent of the Boiler Code in Par. 257.

Case No. 216

Inquiry: An interpretation is requested of the relation between Section *A* of Par. 275 of the Boiler Code and Sections *B* and *C*. Section *A* would appear to allow 12 per cent additional relieving capacity to a valve than either Section *B* and *C*.

Reply: The Committee purposely limited the requirements for rating of safety valves to 3 per cent increase over that at which the valve is set to blow, that is, one-half the maximum allowable increase in pressure of 6 per cent, so that a margin of safety represented by the difference between 6 per cent and 3 per cent would be provided.

Case No. 217
(Annulled)

Case No. 218

Inquiry: For material to be used as headers and manifolds of superheaters, does that of the open-hearth, extra-heavy, lap-welded steel pipe meet the requirements of Par. 11 and the material specifications of the Boiler Code? It is found that the average analyses of such lap-welded pipe appear to meet the physical and chemical requirements of either the boiler plate steel specifications, or the specifications for steel castings of Class B Grade, although they do not conform fully to either one separately.

Reply: It is the opinion of the Committee that, under the requirements of Pars. 9 and 11, headers and manifolds of superheaters must be constructed from material which in its initial form of plate or skelp, conforms to one or the other of the specifications given in the Boiler Code for wrought steel, or they may be constructed of cast steel of the Class B Grade. See reply in Case No. 208.

Case No. 219

Inquiry: *a* Is the intention under Par. 184*c* of the Boiler Code

to deduct the rivet holes when figuring "the full strength of the plate corresponding to the thickness at the joint"?

b An interpretation is requested of Par. 201, as regards the constant in the formula for staybolts. This paragraph requires that "the spacing of the rivets over the supported surface shall be in conformity with that specified for staybolts," but we fail to find a constant which seems to fit the case.

c An interpretation is requested of the last sentence in the last paragraph in Par. 299 of the Boiler Code which is not quite clear.

Reply: *a* It is not the intention under Par. 184*c* of the Boiler Code to deduct the rivet holes when figuring "the full strength of the plate corresponding to the thickness at the joint."

b The constant *C* used in the formula for rivets shall be that given in Par. 199 for stays screwed through the plates with the ends riveted over. This means that *C* shall be 112 or 120 depending on the thickness of the plate.

c The sentence referred to is intended to convey the idea that fittings on pipe connections or in other fittings that are used between the main steam nozzle of the boiler and the boiler itself need not conform to the dimensions given in Tables 16 and 17.

CASE NO. 220

(In the hands of the Committee)

CASE NO. 221

Inquiry: Is it necessary under the requirements of the Boiler Code that small vertical tubular boilers such as are used for clothes-pressing, vulcanizing and laundry service, shall be fitted with gage cocks when a water gage glass is attached?

Reply: It is the opinion of the Committee that a boiler of this type that is operated with a fixed water level, should be fitted with both water gage glass and gage cocks; or two gage glasses as indicated in Par. 294.

CASE NO. 222

Inquiry: What is the application of the limitation of length of staybolts given in Par. 200 of the Boiler Code, that must be drilled with tell-tale holes in their outside ends? Does this length of staybolt apply to inside distance between plates stayed, or to the outside length of the bolt over all?

Reply: Par. 200 of the Code specifies that "staybolts used in waterlegs of water-tube boilers shall be hollow or drilled at both ends irrespective of their length." Par. 220*d* specifies that "the length of a stay between supports shall be measured from the inner face of the stayed plates."

CASE NO. 223

Inquiry: Is it necessary under the requirements of the Boiler Code to provide staying in a single flue boiler 19½ in. in diameter by 43 in. high, having a 16½ in. furnace, crown sheet of which is connected to the top head of the boiler by a 6-in. flue?

Reply: Inasmuch as the diameter of the furnace is less than 18 in., it is evident that under the requirements of Par. 239, the furnace will not require staying. There remains, therefore, only the crown sheet, top head of the boiler and the flue to be considered. Par. 203*d* or the latter part of Par. 216 are applicable to the crown sheet and top head, if formed from flat sheets. If, on the other hand, the crown sheet and top head are dished, the maximum allowable working pressure is calculated from Par. 195. Par. 241 applies to the flue.

CASE NO. 224

Inquiry: Is it necessary that fire-box steel of lower tensile strength than specified in Par. 28*a*, the use of which is sanctioned in Par. 28*c*, shall have a minimum carbon limit of 0.12 per cent as specified for fire-box steel in Par. 25?

Reply: The minimum carbon limit of 0.12 per cent given in Par. 25 applies to fire-box steel having a tensile range of 55,000 to 65,000 lb. per sq. in. and does not apply to steel of a lower tensile strength, the use of which is sanctioned in Par. 28*c*.

CASE NO. 225

Inquiry: Is it necessary under the requirement of Par. 185 of the Boiler Code to plane down to ½ in. the thickness of the shell plate and heads at head seams, or does this requirement apply to girth seams in shell plates only?

Reply: It is the intent of the Code that Par. 184 shall apply to the plates at all circumferential joints on the shell of a horizontal return tubular boiler where exposed to the fire or products of combustion. It therefore applies to a joint between the shell and the head where the joint in the shell is exposed to the products of combustion, in which case the plate is reduced in thickness if over 9/16 in. in thickness, but the flange of the head is not so reduced.

CASE NO. 226

Inquiry: Is not the basis of determination of the relieving capacity of pop safety valves given in Par. 274 of the new edition of the Boiler Code a misprint? The bases of 6 lb., 5 lb., and 3 lb., of steam per hour per sq. ft. of boiler heating surface for the different types of boilers, do not seem to be in line with the other data given in the Boiler Code and not in line with good practice.

Reply: The decision to base the required minimum capacity of safety valves on heating surface was made by the Committee as a result of investigation of general average of operating duty for boilers in practice, it having been found that water-tube boilers rarely exceed a condition of forcing which will evaporate more than 6 lb. of steam per hour per sq. ft. of boiler heating surface, whereas 5 lb. per hour seems to be the limit for high pressure boilers of any other type; similarly practice with boilers operated at pressures of 100 lb. and under, indicated that 3 lb. of steam per hour was a reasonably high figure. These relieving rates were therefore adopted; the provision of Par. 270 limiting the rise of pressure to 6 per cent above the maximum allowable working pressure, being ample for protection against any boiler emergency, as in case the evaporation is over the figure specified additional safety valve capacity must be added to meet this requirement.

CASE NO. 227

Inquiry: *a* Is Par. 12 of the Boiler Code intended to prohibit the use of cast iron on boiler nozzles, flanges and supporting lugs for any temperature or pressure?

b How far from the boiler are the Rules of the Boiler Code intended to apply? That is, do they cover beyond the second stop valve and do they extend indefinitely along the header and steam pipe?

Reply: *a* Par. 12 is not intended to prohibit the use of cast iron for supporting lugs or for boiler nozzles or flanges, provided such nozzles or flanges are not attached directly to the boiler, or used for temperatures in excess of 450 deg. fahr.

b The rules are intended to apply to the boiler structure only as far as and including the nozzles or flanges attached directly to the boiler and to the various accessories and appliances as specified. In Par. 305 of the Code, provisions are made to allow for expansion and contraction of steam mains and for the use of steam reservoirs on the steam mains in case there are pulsations of the steam currents that might cause vibration of the boiler shell plates. This paragraph is included for the protection of the boiler and is not intended to have a bearing on the general subject of design of steam mains.

Circular 79, issued by the Bureau of Standards and prepared by G. W. Vinal and H. D. Holler, summarizes the available information on dry cells as to materials and methods of construction, and presents an elementary theory of their operation.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of MECHANICAL ENGINEERING by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

Pumping Machinery Used by Service of Supply of American Expeditionary Forces in France

TO THE EDITOR:

On the writer's return to America you asked for a statement regarding the nature of the work upon which he was engaged in connection with water-supply problems in France. The following account is therefore sent for your consideration:

The Water Supply office of the Headquarters Lines of Communication was first located in Paris, where it continued until January 13, 1918, when it was removed to Tours. There were changes in nomenclature during the war and finally the office was under the Headquarters Service of Supply, Service of Utilities, Department of Construction and Forestry.

The work included all the water-supply problems except those at the front, which were under another closely coöperating office at the Headquarters of the Chief of Engineers, A. E. F.

I was assigned to duty in the Water Supply office late in October, 1917, shortly after arriving in Paris, and continued the work until the end of the year 1918, when I left Tours en route to the United States. During this time I was largely responsible for the general policy regarding pumping machinery. The following information on the scope of the work is based on a report submitted by an assistant, Oscar G. Goldman, First Lieutenant of Engineers:

On the entry of the United States into the world war and on the dispatch of troops to France, the question of the water supply became of great importance. This included the supplying of camps and hospitals, as well as the railroads, in many cases necessitating the development of new supplies, in some, increasing the already existing French supply, while in others, simply assuring the French supply.

The necessity for the immediate delivery of the water to the point in question meant the development of the nearest supply, either by the sinking of deep wells or by developing the supply from the nearest stream or canal.

This required the use of pumps, the type depending upon the supply utilized and the elevation to which the water had to be delivered. Another feature affecting the pump installation was the size of discharge main available, it being necessary in many cases to install two discharge mains in default of the proper size of pipe for a single line.

Pumps which were expected to be used were estimated in a general way in regard to type, quantity of water to be pumped per minute, and head against which they were to operate. These pumps were tabulated and placed on order in the United States and supplied on monthly priorities, the number requested being estimated according to expected use.

The pumps were placed in two main classes, centrifugal and piston. Several other types were also ordered such as deep-well, steam, and air-lift pumps. The following was the general list of pumps placed on order in America:

CENTRIFUGAL PUMPS		PISTON PUMPS	
Gal. per min.	Head, ft.	Gal. per min.	Head, ft.
200	40	50	150
100	75	60	175
200	75	100	200
100	150	40	460
200	150	175	460
350	250	...	...

Pending deliveries from America, orders were placed with several French manufacturers for pumps for immediate use. Also, where special pumps were required, it was intended to obtain them from French sources.

With the French manufacturers were placed orders for the following centrifugal pumps:

Capacity, gal per min.	Head, ft.	Capacity, gal per min.	Head, ft.
100	50	200	250
100	100	350	50
100	150	350	100
100	200	350	150
200	50	350	200
200	100	350	250
200	150	350	300
200	200	...	...

Piston pumps were also ordered with capacities of 25 gal. per min. (260 ft. head) and 44 gal. per min. (60, 100 and 130 ft. head, respectively).

At the beginning of the war, the pumping machinery used by the American Army was either sent to the depot at Gievres or to Is-sur-Tille and from there shipped to the various jobs. Later it was decided to concentrate all this material at Gievres for distribution.

Nearly all requisitions for pumps were handled by the Water Supply Section of the Division of Construction and Forestry, and as each one was filled a card index was kept showing the type of pumps shipped and also the conditions under which they were to be operated. The pumps thus sent out were later tabulated and in this way a fairly good estimate was arrived at showing the pumps needed or which would be required, as well as the number of each such type, assuming of course that the future demands would be similar to those of the past. It was found that 25 piston pumps and 50 centrifugal pumps were required per month, in the following quantities and sizes:

CENTRIFUGAL PUMPS			PISTON PUMPS		
No.	Gal. per min.	Head, ft.	No.	Gal. per min.	Head, ft.
15	150	100	15	60	175
7	225	100	4	25	300
15	225	150	3	50	300
13	150	200	4	100	300

Of the thirteen 150-gal. centrifugal pumps, three were used in series with another pump, thereby requiring it to be of the reinforced type. The ordinary French pump was built to stand a static pressure of 200 ft. while in the reinforced type castings were made for a static head of 500 ft.

Not many steam pumps were used for water-supply work as it was almost impossible to obtain boilers. Those of the smaller capacities were used by the Forestry Section for boiler feed pumps as a standby to injectors in the operation of the sawmills, and practically all of these were of American make. In several cases triplex pumps were used as boiler-feed standbys when steam pumps were not available.

In several of the deep wells, air-lift installations were made, in many cases of the ordinary type. In some cases a special air-working cylinder was installed, known as the Weber subterranean pump, thereby making it possible to force the water directly into the supply tank, located a considerable distance and at a higher elevation from the well. Direct-connected, straight-line, gas-driven compressors were used, mounted on wheels, with a capacity of 90 cu. ft. of free air per min., against a head of 100 lb. per sq. in.

The majority of the pump installations were belt-driven. At first fiber belting was furnished, but due to the high belt velocities it was found very difficult to keep the lacings from cutting through the holes. Later, leather belting was furnished and no further trouble was experienced.

Belt velocities on French installations usually varied between 4100 and 4500 ft. per min., with a few cases as high as 4875 ft. per min. These velocities are not considered high by the French manufacturers and it was stated by the Rateau Company that they usually signed for velocities of between 4900 and 5700 ft.

Wherever electric power was available, it was desirable to install electric-motor-driven pumps. This was not always possible, as electric motors and apparatus were very difficult to obtain in

France and those from the United States had not been received until late. When American motors were available it was not always possible to use them, due to their lower speeds. Many of the French motors supplied ran at 2850 r.p.m., full-load speed, while others were rated at 1425 r.p.m. The electric motors obtained from America had a speed of about 1000 r.p.m. and with the difficulty of obtaining pulleys it was almost impossible to use them with the French pumps.

For railroad water supply the usual installations consisted of gasoline-engine, belt-driven pumping units. In most cases these plants consisted of two or more units, an extra unit being installed as a standby, all units being of the same capacity, so that should one unit have need of repairs, the plant could still supply the needed amount of water. Where electric power was available but found to be unreliable, gas-engine standby units were installed, not of the total capacity of the entire plant, but of such capacity as to have a certain percentage of water available.

The gas engines used for most of the installations were of the high-speed automobile type. The French engines had a range of speed of from 1200 to 1500 r.p.m., while those of the stationary type had a range of 600 to 1000 r.p.m.

The French manufacturers claimed these high-speed engines had been in continuous service, being used by the armies of England and France throughout the period of the war, and had given good service, yet whenever possible the heavy-duty, or low-speed, American-made gas engines were used.

Having thus far discussed in general terms the type of pumps and power used by the American Army along the lines of communication, a few special installations will now be explained.

The number of trains, including freight and troop, passing over the roads having increased many times that before America entered the war, it became necessary to increase the railroad water supply, and in some cases install new watering points.

One of these pumping stations was located at Foecy, Department of Cher. This plant contained two centrifugal pumps made by the Rateau Company, Paris, of the PFP-28-R type, belt-driven by a Chapuis-Dornier automobile-type 15-hp. gas engine, with 4-in. single-ply leather belting, rawhide lacing being used. The amount of water required was 140 gal. per min. against a total head of 150 ft., the discharge being two 4-in. cast-iron pipe lines with a length of about 4300 ft. The water was discharged into a 50,000-gal. railroad water tank, and supplied to the locomotives through two 10-in. standpipes.

The centrifugal pumps were single-stage, diffuser type, running for the condition mentioned above at 1890 r.p.m. and requiring about 10.5 hp. at the shaft.

At Perigueux, Department of Dordogne, the pumping station located on the Dronne River consisted of two Dumont centrifugal pumps direct-connected to 15-hp. Chapuis-Dornier gas engines. Each pumping set really consisted of two pumps bolted together on the same shaft, with special fittings, so that they could either be operated in series or parallel. Operating in series at 1300 r.p.m. each pump would supply 264 gal. per min. against a head of 98 ft., while in parallel the pumps would deliver 528 gal. per min. against a head of 49 ft. In this station these pumps were operated in series. The water was supplied to a 100,000-gal. concrete reservoir through a 6-in. discharge line about 700 ft. in length and then through a 10-in. line of about 1000 feet to the reservoir. This 10-in. line was also used as the supply line to two 10-in. standpipes for supplying water to the locomotives.

For hospital supply, the pumping station usually contained more pumping units than that installed for railroad purposes. Several of the larger stations will be hereafter described.

At Allerey, Department of Saone et Loire, the maximum amount of water needed was figured at 460,000 gal. per day, the hospital being one of 10,000 beds with a crisis expansion to 20,000. Test wells were sunk in a gravel pit located about 8500 ft. from the extreme end of the hospital and it was at first expected to get all the water from this location by sinking an additional well about 200 ft. from the first. Two centrifugal pumps of the PFP-28 type, single-stage, made by Rateau Company, Paris, rated at 189 gal. per min. against a head of 207 ft., running at 2100 r.p.m., belt-driven by 20-hp. Charron automobile-type gasoline engines, were installed. Later it was determined that the needed amount of water could not be obtained from the two wells, and it was decided to install another station on the Saone River about 2200 ft. from the wells. In this station two Rateau centrifugal pumps of the PFP 28-R single-stage type were installed, rated at 150 gal. per min. against a head of 200 ft., running at 2160 r.p.m., belt-driven by a 30-hp. Bignan automobile-type gasoline engine.

The water was pumped to a 100,000-gal. concrete reservoir through a 6-in. cast-iron main as far as the hospital and from there on through an 8-in. main, which was part of the hospital distributing system, with a length of 5500 ft. In each station the pumps were to be operated so as to give 190 gal. per min. against a head of 200 ft. This necessitated speeding up the pumps of the station located on the river to about 2300 r.p.m.

At Joue-les-Tours, Department of Indre et Loire, a 2000-bed hospital was erected. Here the water was pumped from an 8-in. well about 600 ft. deep by means of compressed air to a 11,000-gal. storage tank at about 85 ft. above the top of the well, a Weber subterranean cylinder being used. The amount of water delivered was about 100 gal. per min., through a 4-in. main about 300 ft. long, the compressor used being one of the Chicago straightline 15-hp. gas-engine-driven type, rated at 90 cu. ft. of free air per min. at 100 lb. per sq. in. The cylinder was set at about 265 ft. from the top of the well. When the well was not operating the water stood at about 25 ft., but as soon as the pump was started the water level receded to about 50 ft. from the surface of the ground. The starting pressure was about 125 lb. per sq. in. at the well, while the running pressure dropped to about 108 lb.

In another deep well, driven about 25 ft. from the other to a depth of about 500 ft., an ordinary nozzle-type air lift was installed with a 2-in. discharge and a $\frac{1}{2}$-in. air line. The air was supplied from a gasoline-engine belt-driven Worthington compressor rated at 30 cu. ft. of free air per min. against a pressure of 100 lb. per sq. in. A rough test showed that about 20 gal. per min. could be obtained at the tank, and it was proposed to use this installation as a standby.

Bassens, located near Bordeaux, was one of the ports developed by the American Army. The work there consisted in building new wharves, railroad yards, camp sites, as well as a large refrigerating plant.

The supply for the docks, railroad yards and camps was supplied from two artesian wells. At the first well, two direct-connected electric-driven 26-hp. centrifugal pumps of the PFP-28-S type were installed for 395 gal. per min. against a head of 130 ft., running at 1430 r.p.m. The "S" type pumps are two single-stage pumps bolted together on the same shaft.

At the second well two PHP-20 direct-connected, electric-driven, single-stage centrifugal pumps were installed, rated at 395 gal. per min. against a head of 130 ft. at 2800 r.p.m.

The distributing system consists of 8-in. and 6-in. Universal cast-iron pipe. The first station was located almost 8000 ft. from the docks, the discharge main being 8 in. in diameter, while the second was about 5000 ft. distant, the discharge main consisting of 6-in. pipe.

For the refrigerating plant the pumping station was situated on the banks of the Garonne River, and consisted of three direct-connected, electric-driven, single-stage centrifugal pumps of the PFP-36 type, rated at 500 gal. per min. against a head of 160 ft., running at 1430 r.p.m., the motor being one of 36 hp. The discharge line was of 12-in. cast-iron bell-and-spigot pipe with a length of about 3000 ft.

The elevation of the water level varies about 21.5 ft. between extreme high and low water, and it was therefore necessary to set the pump in a concrete pit about 9.5 ft. deep, so that at extreme low water the suction lift would be about 13 ft.

The pumps used at Bassens were among a large number especially designed for each condition by the Rateau Company of Paris.

W. B. GREGORY,
Major of Engineers.

New Orleans, La.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

The Thermal Testing Plant of The Engineering Experiment Station, The Pennsylvania State College

THE Thermal Testing Plant of The Pennsylvania State College is one of the best-equipped plants of its kind. It consists of two buildings, the generating plant and the calorimeter building.

The generating plant is a brick building 50 ft. by 18 ft. Its equipment consists of a complete 3-ton experimental refrigerating system of the compression type, and a variable-speed circulating pump for carrying the brine to the calorimeter building. The installation is such that the plant can be driven either by electricity or by steam. The observer's bench is located in this building and contains the necessary voltmeters, ammeters, rheostats, etc., for measuring the electrical heat supplied to the test box and switches and a wheatstone bridge for measuring the temperatures registered by the resistance thermometers in the calorimeter building. In addition to the apparatus listed there are two experimental house-heating boilers located in this building.

The calorimeter building is a brick building 32 ft. by 32 ft. and contains, centrally located, an outside calorimeter room of corkboard construction, 20 ft. by 20 ft. by 10 ft. high. This room is fitted with 550 ft. of 1¼-in. brine coils distributed over three sides of the room and the brine flow can be regulated by means of the circulating pump in the generating plant, to hold the temperature to within a variation of about 1 deg. fahr. The test box which has been used in the room is a 5-ft. cube of 3-in. cork board, with one side removable. Within this calorimeter room a second calorimeter room 10 ft. by 7 ft. by 10 ft. high has recently been built and since its completion it has been used for all the testing work. It is of somewhat similar construction and is fitted with 690 ft. of 1½-in. brine coils located on the four side walls and the ceiling. This inner room is so located that space is afforded in the large room for experimenting with large test boxes. This small calorimeter room is fitted with a Tagliabue thermostat which so regulates the flow of brine that the room temperature can be held within 5 deg. fahr. and in several cases no difficulty has been experienced in maintaining a temperature which has not varied a tenth of one degree for as long as three hours. The thermostat can be adjusted from the outside of this room, so as to regulate at any desired predetermined temperature. The compressed air necessary for the operation of this instrument is supplied from an adjoining engineering building. To avoid as much as possible the evaporation of the condensed moisture from the brine coils, drip pans and drain pipes have been suspended under the various coils. The test box being used at the present time is one of wood and felt construction 32 in. by 32 in. by 16 in. It has removable blanks 2 ft. square for which similar-sized blanks of the material to be tested can be substituted. The electrical heat is furnished to the inside of the box by means of a coil of manganin resistance wire which is located near the bottom of the box. A very small electric fan is used for circulating the air inside of the box. A "sandwich" heating element is also available and can be substituted for the one now in use. It consists of coils of manganin wire placed between two perforated asbestos boards 2 ft. square, and is designed to be set vertically in the center of the box and to be used without the circulating fan. Another test box is available. The heating element of this box is an asbestos cube whose six faces are mounted with manganin resistance wire, the cube being encased in a tight-fitting galvanized-iron box. Over this heating element a casing of the material to be tested is constructed, the cube being entirely encased in the "unknown" material.

Both live current and storage-battery current are available for heating the various resistance coils. Temperature measurements are taken by means of specially designed electrical resistance thermometers. Flat nickel spirals (about 1/50 in. thick and 1¾ in. in diameter) are used for temperatures near and on surfaces, and small nickel coils encased in cylindrical cases of polished metal are used for all other temperatures. These thermometers are connected to the wheatstone bridge in the generating building.

For determining the humidity in the calorimeter room a wet-and-dry-bulb thermometer is available, and so located that readings can be taken through a triple-sash glass window, and to have the readings compare with those of a sling psychrometer a current of air is blown over the bulbs by means of an electric fan until the readings become constant, a period of about three minutes being sufficient. If it is desired to determine the effect of air velocity, electric fans are available for forcing air against the surfaces of the test box.

In heat-transmission studies the method of testing finally adopted as combining rapidity and accuracy in such degree as to be consistent with the limitation of the apparatus is to raise the temperature of the test box as quickly as possible to several degrees above the required equilibrium temperature as predetermined by an approximate calculation for a given wattage. The current is then lowered and adjusted to give the required input of heat and when the temperature drops no faster than 2 deg. fahr. per reading (20 min.) the voltage is dropped about 10 per cent for one interval and then raised to the required voltage. The current from the storage battery being subsituted for the 110-volt d.c. current at this time to maintain a constant heat input. If the temperature drops slightly and then rises and practically holds its former value, there is reason to believe that the box is "saturated" and that the equilibrium value has been reached. The test is then continued for about two hours, further testing being unnecessary. Voltage, amperage and temperature observations are made every twenty minutes and humidity and brine observations every hour.

The Engineering Experiment Station of The Pennsylvania State College will be glad to coöperate in the testing work incident to the development of new insulating materials and methods and the more efficient use of those already available.

Results of tests performed in the Thermal Testing Plant of The Pennsylvania State College appear in the following publications:

Preliminary Report from the Thermal Testing Plant of The Pennsylvania State College, by J. A. Moyer, at the Third International Congress of Refrigeration. 1913.

The Effect of Velocity and Humidity of Air on Heat Transmission Through Building Materials, by J. A. Moyer, J. P. Calderwood and M. P. Helman, Bulletin 16, The Engineering Experiment Station, Pennsylvania State College; also *A. S. R. E. Journal*, November 1915.

Determining Heat Transmission of Compound Walls with Tests on Insulated Steel Car Sections, by A. J. Wood, *A. S. R. E. Journal*, January 1917.

Report on A Study of Surface Resistance with Glass as the Transmission Medium, by H. R. Hammond and C. W. Holmberg, at the annual meeting of the A. S. M. E., December 1917.

Some Recent Studies in Heat Transmission, by J. A. Wood and R. B. Fehr, *A. S. R. E. Journal*, March 1918.

Report on The Thermal Testing Plant, by R. B. Fehr, Bulletin No. 24, Engineering Experiment Station, Pennsylvania State College.

The present work of the Thermal Plant concerns a study of the comparative insulating values of the various building materials and of air spaces. The future plans include a further study of this work and a study of the insulating values of various numbers and sizes of air spaces.

Steel Research Laboratory Planned for the Carnegie Institute of Technology

Contributed by Thomas S. Barker

THE decision of a number of officials of the leading steel and engineering companies manufacturing rolling-mill machinery, to install an experimental rolling mill and Bureau of Rolling Mill Research under the auspices of the Carnegie Institute of Technology at Pittsburgh, marks not only the beginning of a radical advance in the art of rolling steel and other metals in this country, but an equal advance in the spirit of coöperation among American manufacturers which the industrial leaders have long strived to obtain, and which they recognize as absolutely necessary if this country is to retain its industrial supremacy during the coming period of reconstruction. This Bureau of Rolling Mill Research will have four distinct functions:

1 To investigate and study the physical and mechanical changes taking place in steel and other metals, and the power consumed, during the process of being rolled at various temperatures and speeds.

2 To distribute the information obtained by means of these experiments among the coöperating firms in order that they may put it into commercial use.

3 To provide laboratory facilities in which the contributing companies may conduct experiments and investigate designs of rolls for the production of new sections which they wish to place on the market.

4 To offer courses of instruction to students employed by the contributing interests and to those students who are to specialize in this field and are registered at the Carnegie Institute.

As planned at present the mill will consist of three stands of three-high rolls driven by a 500-hp. variable-speed electric motor. The drive and change-speed gears will be so arranged that any number of revolutions between 4 r.p.m. and 1000 r.p.m. may be obtained. This wide range of speeds will enable a careful study to be made of the effects of speed on power consumed, and physical properties of the steel when rolled and treated under varying conditions.

Both the mill and the drive will be equipped with a complete set of automatic recording instruments and changes in their reading under the varying conditions of rolling mill be recorded. The special stand for measuring the spreading force on rolls is to be equipped with hydraulic cylinders so arranged that the work done to overcome friction at the roll is automatically separated from the work done in rolling the steel.

Another feature of the mill will be a quick-action stop clutch. By means of this clutch the mill may be instantly stopped while a bar is passing through the rolls.

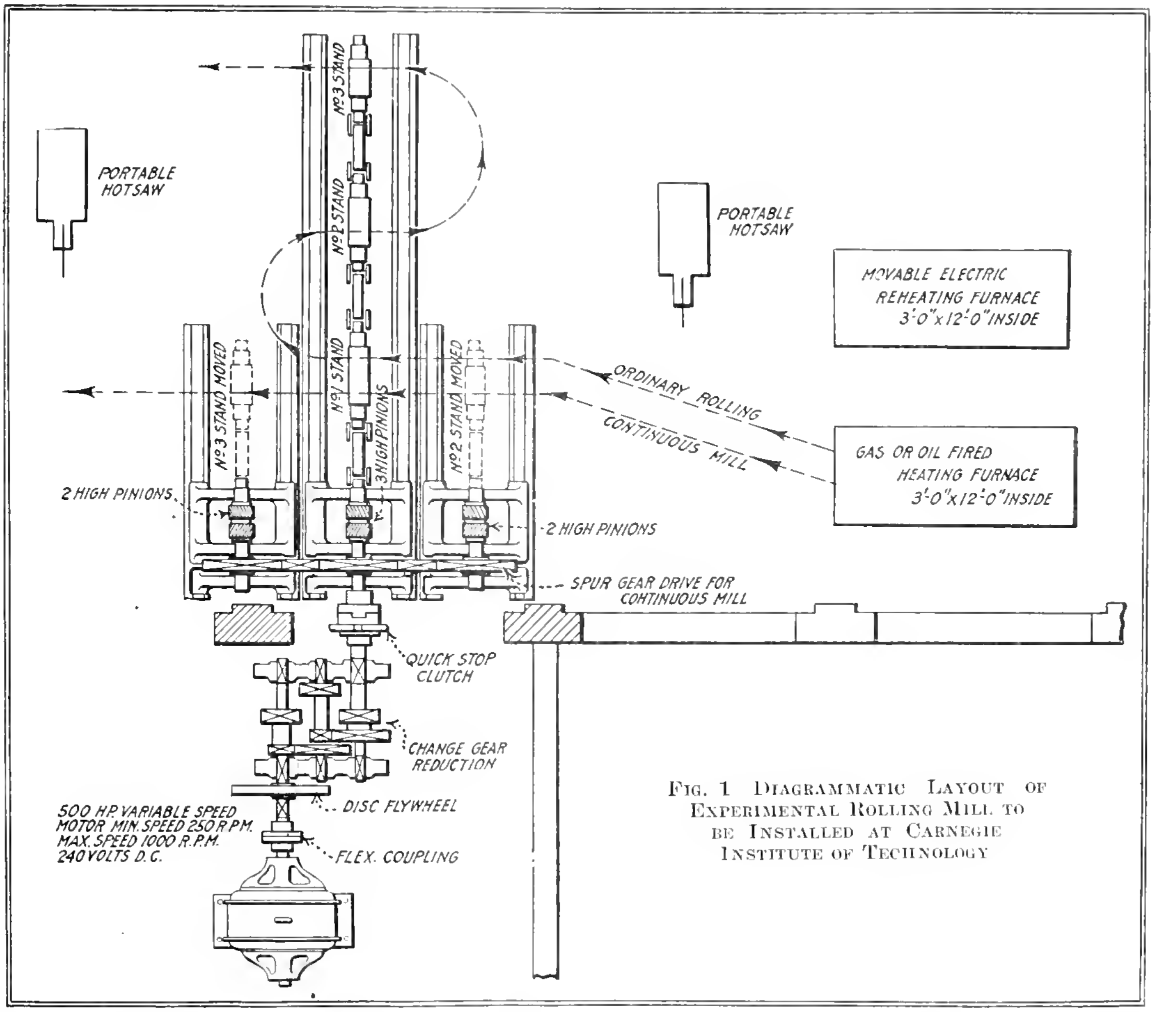

Fig. 1 Diagrammatic Layout of Experimental Rolling Mill to be Installed at Carnegie Institute of Technology

In practical mill work a roller often has to wait days and sometimes weeks before he can catch this condition, as he could not consider the stopping of production while he made a cobble in some particular roll pass that was giving him trouble, and it is mainly by studying the cobbles that the action of the steel can be observed and studied.

By stopping the mill and catching a bar in the rolls the exact action or flow of the steel in that particular pass and with the particular set of conditions under which the mill is operating, will be permanently recorded in the section of bar being pinched by the rolls.

The rolls will then be opened and the bar withdrawn and studied. By this means a student can gain more experience in the rolling of steel and knowledge of the flow of steel during rolling in one year on the experimental mill than could possibly be gained in many years' work on a commercial mill.

Fig. 1 shows a diagrammatic layout of the mill and drive. As will be seen, the three stands may be mounted on one shoe and used as a Belgian train with No. 1 as a rougher, No. 2 stand as

strand or leaders, and No. 3 stand as finishers; or No. 2 and No. 3 stands may be moved as indicated in dotted lines so that all three housings are placed in tandem and the mill will operate as a continuous mill.

When operating in this manner only the upper two rolls would be used, the lower ones being left out and the space for their neck bearings filled up. In order to drive the continuous mill a train of gears is located just outside the pinion housings, the large driving gears being mounted on an extension of one of the pinion necks. Idle gears between are carried by separate adjustable bearings.

By means of a spur gear instead of the usual bevel-gear drive used on continuous mills, the reduction ratio between the stands may be altered by changing only one gear instead of two.

In this manner it is hoped that the actual conditions existing in the mills of the contributing members of the Bureau may be easily duplicated in the laboratory, thus enabling any member to experiment on problems arising in his business under conditions which duplicate those in his mills, without excessive expense or without the losses incident to tying up a producing department.

The Bureau will be under the control of a Research Committee who will be composed of members appointed by the contributing interests, and representatives of the Carnegie Institute of Technology. This Research Committee will lay out and oversee all work and transact all business in connection with the Bureau. The entire Department is to be operated on a no-profit basis and all funds subscribed for this work and not used, will be returned to the subscribers.

Among the many problems where research work can be done and on which the information is badly needed by rolling-mill engineers, are

a Separating forces acting on rolls and housings
b Influence of speed on separating forces and on roll-train resistance
c Ratio of roll-neck friction to total roll-train resistance
d Influence of roll diameter, steel temperature, roll velocity and form of projected contact area on spreading
e Greatest deformation which plastic material can undergo without injury while being rolled.

It is planned to demonstrate to students who are studying rolling-mill engineering and roll-pass design the following phenomena:

1 Effect of separating or closing the rolls
2 Effects of "crossing" the rolls
3 Metallurgical effects of many light passes
4 Metallurgical effects of a few heavy passes
5 Rolling of shapes and merchant material
6 Study of plastic deformation and lines of flow
7 Forward slippage in rolling.

Reports Upon Research

A—Research Results

Apparatus and Instruments A1-19 Thermometers for Aeroplane Use. Describes types of construction, design, nature and amount of errors. Aeronautic Instrument Circular No. 39. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments A2-19 Aeronautic Instruments. A complete mathematical theory on elastic fatigue. Circular No. 39. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments A3-19 Altitude Tables. Tables for determining altitude corresponding to various atmospheric pressures, giving results in millibars and other units. Aeronautic Instrument Circular No. 3 Supplement. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments A4-19 Standard cement samples for standardizing 200 mesh sieves. 180-gram containers will give enough material for three tests. These may be purchased at 25 cents each. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

B—Research in Progress

Properties of Engineering Materials A1-19 Concrete Molds of Paper. Tests of 1:2:4 concrete made in steel molds and paper molds. Comparative tests gave similar results, showing that paper mold can be used for test samples. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Air B2-19 Coefficient of Friction in Air Ducts. University of Michigan, Ann Arbor, Mich. Address Dean M. E. Cooley.

Apparatus and Instruments B1-19. Profile projecting lantern with short screen distance for magnification. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments B2-19 Thread-angle measurements by three-wire method. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Automotive Vehicles and Equipment B2-19 Car Performance Curves. The determination of values, curves of acceleration, fuel economy at various speeds and speed ranges in accordance with specifications of the Research Division of S. A. E. University of Michigan, Ann Arbor, Mich. Address Dean M. E. Cooley.

Cement and Other Building Materials B1-19 Marble. Permanent increase in dimensions due to alternate heating and cooling. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Cement and Other Building Materials B2-19 Plaster "Popping." A study to determine the cause of "popping" in plaster. The investigation includes the use of overburned lime, underburned lime, improperly hydrated lime and unclean sand. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Cement and Other Building Materials B3-19 Sand-Lime Bricks. An investigation of the time of curing of sand-lime bricks. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Heat B3-19 Thermal Expansion of Glass, Dental Alloys, Cements, Human Teeth and Johannsen Gages by Interference Methods. Permitting measurements within 0.06 micron (about 2 millionths of an inch). Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Heating B1-19 Radiators, Hot-Water. Test of hot-water radiators. University of Michigan, Ann Arbor, Mich. Address Dean M. E. Cooley.

Heating B2-19 Radiators. Heating Effect as Influenced by Type, Style and Location. University of Michigan, Ann Arbor, Mich. Address Dean M. E. Cooley.

Insulation B1-19 Magnesia Heat Insulation. A continuation of the work reported at the December meeting of The American Society of Mechanical Engineers, 1918. Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa. Address Director R. F. Bacon.

Internal-Combustion Motors B2-19 Combustion Efficiency of Automobile Engines. University of Kansas, Lawrence, Kan. Address Dean P. F. Walker.

Internal-Combustion Motors B3-19 Delivery of Power from Multi-Cylinder Engines. University of Kansas, Lawrence, Kan. Address Dean P. F. Walker.

Properties of Engineering Materials B2-19 Concrete Floor Surfaces. A test of 31 slabs subjected to actual traffic for five months, testing out magnesium fluosilicate, varnishes and paints, waxes and three other hardeners. To date the greater part of the slabs are almost free from dust and those treated with magnesium fluosilicate compounds are very hard. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Properties of Engineering Materials B3-19 Bearing Metals. Ex-

perimental study has been planned and submitted to manufacturers for consideration and suggestions. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Textile Manufacture and Clothing B1-19 Asbestos Textiles. An investigation for the purpose of standardizing specifications for asbestos textiles. Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa. Address Director R. F. Bacon.

Textile Manufacture and Clothing B2-19 Investigation of Tautness of Airplane Fabrics by Means of Special Meter. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Transmission B4-19 Universal Joints. A study of problems of the universal joint used in automobile transmissions. University of Kansas, Lawrence, Kan. Address Dean P. F. Walker.

C—Research Problems

Apparatus and Instruments C1-19 Study of Gaging Systems in Manufacturing Plants. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments C2-19 Heat Treatment and Chemical Composition of Steel for Gages. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments C3-19 Screw-Thread Gages. Possible errors in screw-thread gages and discrepancies in fit of plug and ring thread gages. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments C4-19 Gages. Utility of flush-pin gages and built-up snap gages. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments C5-19 Gage Marking. The proper method of etching lines on gages for correctness and distinctness. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments C6-19 Indicators for Machine Work. The design of indicators more sensitive and constant than those in present use. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments C7-19 Gage Salvaging. The possibility of salvaging gages by electrically nickel plating gage surfaces. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Metal Manufactures C1-19 Lapping. A Study of Lapping Compounds to Determine Suitability for Certain Purposes. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Metal Manufactures C2-19 Cutting Oils. The effect of different lubricants on cutting quality of taps. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Metal Manufactures C3-19 Thread Grinding. The correct principles of thread grinding. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Metal Manufactures C4-19 Rusting of Small Steel Parts. A method to prevent rust in small steel parts, as those in a watch, without destroying the finish. Elgin National Watch Co., Elgin, Ill. Address G. E. Hunter, Gen. Supt.

D—Research Equipment

Air D1-19 Compressed-Air Plant. Large air compressor equipped for study of air through orifices and nozzles and under cooling. Johns Hopkins University, Baltimore, Md. Address Prof. A. G. Christie.

Air D2-19 Vacuum Cleaners. Equipment to test one type of vacuum cleaning machine for power, air handled and vacuum required for vacuum cleaning. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Air D3-19 Air Compressor for Studying Problems in Air Compression. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Apparatus and Instruments D3-19 Devices and Instruments for Measuring Radii of Profile Gages. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments D4-19 Balanced Micrometer Holder for Making Diameter Measurements of Thread Gages. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Apparatus and Instruments D5-19 The Hoke Precision Gage Disks. Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Carnegie Institute of Technology D1-19. Steel Research Laboratory. See Mechanical Engineering for May, 1919. Carnegie Institute of Technology, Pittsburgh, Pa. Address Thomas S. Baker.

Fuels—Gas, Tar and Coke D1-19 Gas By-Products Laboratory. Complete laboratory for studying gas production and by-products. Equipped to study all kinds of problems arising in ovens, such as low temperature, distillation of coal, coking properties, by-products and gas-forming capacities of various coals and lignites. Johns Hopkins University, Baltimore, Md. Address Prof. A. G. Christie.

Heat D1-19 Heat Transmission Through Building Materials. Cube 6 ft. on one side equipped with heating elements and thermocouples to determine heat transfer. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Heating D1-19 Direct and Indirect Radiators with Fans, Air Washers and Thermostats. Instruments for studying problems of heating and ventilation. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Heating D2-19 Warm-Air-Furnace Testing Plant. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Heating D3-19 House-Heating Boilers. Several types of sectional heating boilers equipped to study problems in heating water and generating steam. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Heating D4-19 Thermal Testing Plant. Pennsylvania State College. See Mechanical Engineering for May, 1919, page 464. Pennsylvania State College, State College, Pa. Address Prof. A. J. Wood.

Internal-Combustion Motors D1-19 Diesel Engine of 80 Hp. For investigation with different types of oil-spray nozzles and other devices for injecting fuel. Johns Hopkins University, Baltimore, Md. Address Prof. A. G. Christie.

Internal-Combustion Motors D2-19 Plant for Testing Gas Engines, Producers Using Bituminous Coal, Automobile Engines and Other Problems of Such Motors. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Internal-Combustion Motors D3-19 Four-Cylinder Gas-Engine Direct-Connected to 75-Hp. Sprague Electric Dynamometer. Complete equipment. Apparatus arranged for testing motor fuels. Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa. Address Director R. F. Bacon.

Johns Hopkins University D1-19 Mechanical Engineering Laboratory Equipment.

1 Gas by-products laboratory equipped to study problems in gas manufacture and the by-products thereof.
2 Spray Pond. Apparatus to study cooling of water.
3 Compressed-Air Plant. Equipment to study flow of air through orifices and nozzles.
4 Refrigeration. Fifteen-ton refrigerating system with provisions for measuring fluids.
5 Buckeyemobile. A 75-hp. buckeyemobile unit for heat-transfer tests.
6 Diesel Engine. An 80-hp. Diesel engine for studying fuel oils. Address Prof. A. G. Christie, Johns Hopkins University, Baltimore, Md.

Mellon Institute D1-19 Unit Plants. The Mellon Institute has installed small-scale complete equipments to study process development by the construction of unit plants in which the process was carried out commercially, although of smaller size than the final commercial installation. Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa. Address Director R. F. Bacon.

Metallurgy and Metallography D1-19 Furnaces, ovens, grinders, crushers, vacuum dryers and filter presses. Mellon Institute of Industrial Research. University of Pittsburgh, Pittsburgh, Pa. Address Director R. F. Bacon.

Metallurgy and Metallography D2-19 Steel Research Laboratory, Carnegie Institute of Technology. See Mechanical Engineering for May 1919, page 465. Address Thomas S. Baker, Secretary, Carnegie Institute of Technology, Pittsburgh, Pa.

Pennsylvania State College D1-19 The Thermal Testing Plant of the Engineering Experiment Station. See Mechanical Engineering for May, 1919, page 464. Pennsylvania State College, State College, Pa. Address Prof. A. J. Wood.

Refrigeration D1-19 Refrigerating Plant for Accurate Determination of Ammonia and Brine Used in Refrigeration. Fifteen-ton refrigerating system equipped for weighing ammonia and measuring brine. Johns Hopkins University, Baltimore, Md. Address Prof. A. G. Christie.

Refrigeration D2-19 Compression and Absorption Apparatus for Experimental Work. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Steam Power D1-19 Spray Ponds. Spray pond equipped with nozzle to determine the laws of cooling water by such means. Johns Hopkins University, Baltimore, Md. Address Prof. A. G. Christie.

Steam Power D2-19 Buckeyemobile of 75 Hp. for Heat-Transfer Tests. Johns Hopkins University, Baltimore, Md. Address Prof. A. G. Christie.

Steam Power D3-19. Engines and Turbines for Use with Saturated and Superheated Steam. University of Illinois, Urbana, Ill. Address Dean C. R. Richards. See University of Illinois, *D1-19.*

Steam Power D4-19 Boiler Experimental Work. Water-tube boiler equipped with chain-grate stoker with independent superheater and economizer for experimental work. University of Illinois, Urbana, Ill. Address Dean C. R. Richards.

Textile Manufacture and Clothing D1-19 Machinery for Wool Manufacturing, Including Spinning and Weaving. Installed for experimental purposes at the Bureau of Standards, Washington, D. C. Address Director S. W. Stratton.

Transmission D1-19 Belt-Testing Apparatus. Two Sprague electric dynamometers of 100 hp. each. Mellon Institute of Industrial Research, Pittsburgh, Pa. Director R. F. Bacon.

E—Research Personal Notes

Apparatus and Instruments E1-19 Gage Section—Bureau of Standards.

During the last few months the Gage Section of the Bureau of Standards has developed several new methods of making measurements of gages and gaging instruments. These include:

1 Simple methods of measuring effective pitch diameters of taper pipe-thread gages using three wires.

2 The use of light-wave interference methods for making length comparisons and for testing flatness and parallelism of surface of flat end standards.

3 Application of sliding taper parallel for measuring snap gages.

4 The use of mechanical indicator for testing plain ring gages. Address S. W. Stratton, Bureau of Standards, Washington, D. C.

Apparatus and Instruments E2-19 Gage Section—Bureau of Standards.

The Gage Section of the Bureau of Standards has made several communications which may be had under certain conditions by application to the Bureau. For the information of those interested, the following list is given:

B462—Test of Micrometer Calipers. (To be revised before distribution.)

B466—Procedure of Tests and Explanation of Reports of Munition Limit Gages by Bureau of Standards.

B467—Gage Tolerances Used by Ordnance Department, U. S. A.

B500—Inspection of Pipe Thread Gages in the Fields. (To be revised before distribution.)

B503—Course of Instructions Covering Measurement and Use of Munition Limit Gages. (Obsolete but available.)

B505—Questionnaire for Information on the Standardization of Screw Threads.

B506—Important Screw-Thread Systems.

B507—Dimensions of Briggs Standard Pipe Gages.

B511—Reminders Regarding Microscopes. (Not intended for general distribution, but obtainable on request.)

B513—Service Available at the Bureau of Standards Gage Laboratories.

B515—Formula for Determining Effective Diameter of Buttress Threads. (Not ready for distribution.)

B516—Tables of Dimensions of Foreign Threads. (Not ready for distribution.)

B517—Thread Form and Clearance of U. S. Standard Thread Gages. (Not ready for distribution.)

Address Director S. W. Stratton, Bureau of Standards, Washington, D. C.

Cement and Other Building Materials E1-19 Concrete Shear Tests.

The Editor of *Engineering News-Record* calls attention to the fact that the question of shear in concrete is in a most unsatisfactory state in spite of the number of tests which have been made on this subject. He calls attention to a series of tests described in the *News-Record* for Feb. 27, 1919, by Slater, and states that these investigations should be carried further. The Bureau of Standards is willing to carry on this work if funds may be provided for the work, and those interested might take up this matter with members of Congress for support.

General E3-19 Steel Treating Research Society.

The Steel Treating Research Society, with headquarters at Detroit, Mich., W. P. Woodsie, President, and H. G. Kiefer, Chairman of the Detroit Section, is desirous of coöperating with the Research Committee. The work of the Society is outlined from its By-Laws relative to its Standards Committee as follows:

> The duties of the Standards Committee shall be to adopt as standard, steels having the composition of the Society of Automotive Engineers Standard Steels, and to compile in suitable form all existing data regarding the physical properties and heat treatment of the same, or by the supervision of original research work, to establish as standard the heat treatment for the above steels. It shall also be the duties of the Standards Committee to collect all information regarding methods of manipulation and heat treatment and equipment with which to conduct heat treatment, and to adopt as standard the most uniform and desirable methods to obtain the standard physical properties. The work of standardization is not to be limited to automotive steels entirely, but in time may be extended to cover all types of steels and their heat treatment which are known to the art.

Heating E1-19 Heating Researches.

The American Society of Heating and Ventilating Engineers has just begun a comprehensive program of research costing $20,000 per year. Most of the work will be done in connection with the laboratories of the Bureau of Mines at Pittsburgh. No definite information has been received by the Committee on the plans for this research, but as soon as information is received it will be communicated to the Society.

University of Michigan E1-19.

The research personnel of the mechanical engineering department includes Prof. J. E. Emswiler, H. E. Keeler and H. J. Watson in general mechanical engineering and Prof. W. E. Fishleigh and W. E. Lay in automobile truck and tractor investigations.

F—Bibliographies

Petroleum, Asphalt and Wood Products F1-19 Distillation of Oils and Latent Heat of Vaporization. Short bibliography. Address Library, United Engineering Society, 29 West 39th St., New York City.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

AERONAUTICS (See Internal-Combustion Engineering)

BUREAU OF STANDARDS

Physical and Chemical Tests of the Commercial Marbles of the United States, D. W. Kessler. This paper is the first report of the Bureau of Standards in connection with an extensive coöperative program for investigating the building stones of the United States. The other Government departments participating in the work on different phases of the investigation are the U. S. Geological Survey, Bureau of Mines, and Office of Public Roads.

The paper comprises the results of strength tests, water absorption, porosity, specific-gravity, freezing, thermal-expansion, electrical-conductivity and chemical tests on 52 different types of marbles produced in this country. The purpose of the work is to determine the relative value of the different types for building purposes and other special uses.

Compressive-strength tests were made on specimens in the original condition and on specimens after being soaked in water for two weeks. The dry specimens have strength values ranging from 7,850 to 50,205 lb. per sq. in. As a rule the soaked specimens gave lower compressive strengths than the dry, and in a few cases the loss due to soaking was over 25 per cent.

Transverse- and tensile-strength tests are included and show the strength of the specimens when broken perpendicular and parallel to the bedding planes.

The freezing tests made for this report consisted in determining the loss in weight and strength due to 30 freezings and thawings. While these losses were considerable in most cases, some samples showed practically no loss and occasionally a gain in strength was indicated. Hence it was decided that 30 freezings were not enough to give a trustworthy indication of the durability of such materials. An apparatus has been installed which automatically shifts the specimens back and forth between a cold chamber and warm chamber at certain intervals. With the use of this apparatus it is possible to make a great number of freezings which will correspond to several years of exposure to the weather. It is proposed to make extensive weathering tests with this apparatus to determine more definitely the relative effect of frost action on the different marbles as well as other types of building stones.

Electrical-resistivity tests were made on a number of different types to determine their relative value as insulators and resistivity under different conditions of moisture. The results show a considerable range of values, indicating that there is a choice of marble for use in switchboards and allied purposes.

Measurements of the thermal expansion made on a few samples of marble in this investigation show that this material does not expand at a uniform rate even at ordinary temperatures. As the temperature is increased the rate of expansion increases, hence it is not possible to state a coefficient of expansion for marble that will hold good for any very great range of temperatures. Another peculiarity brought out by these tests was the fact that marble when expanded by heating does not contract to its original dimensions as the temperature is lowered, but retains a part of the increase permanently. A number of successive heatings show the same effect, each adding an increment of length to the specimen.

A few cases of warped marble slabs are illustrated and a discussion is made of the causes which may be instrumental in bringing about this warping. (Abstract from Bureau of Standards Technologic Paper No. 123.)

The Viscosity of Gasoline. The short-tube viscosimeters which are in ordinary use for determining the viscosity of lubricating oils cannot be used with gasoline, for which it is necessary to employ an instrument with a much longer outlet tube. The Ubbelohde viscosimeter, primarily designed for kerosenes, appeared suited to the purpose and two instruments of this type were used in determining the relation between time of discharge and viscosity in poises. By a large number of runs with water and ethyl alcohol solutions, liquids of known viscosity, it was found that:

$$\text{Kinetic viscosity} = \frac{\text{viscosity in poises}}{\text{density, g. per cc.}} = 0.0000887\ t - \frac{1.438}{T}$$

where t is the time of discharge in seconds. The published standard dimensions of the instrument give 0.125 cm. as the inside diameter of the outlet tube, and this was found to be 0.129 in the instruments tested. The time of discharge for 100 cc. of water at 20 deg. cent. (68 deg. fahr.) was found to be very close to the specified value of 200 sec. It is therefore suggested that 200 sec. should be retained as standard, but that the diameter of the outlet tube should be changed to 0.129 cm.

In dealing with highly fluid liquids such as gasoline, it is convenient to use the fluidity, or reciprocal of the viscosity in poises, in place of the viscosity. The temperature-fluidity curve is very much more nearly a straight line than is the temperature-viscosity curve. Fluidities were found for thirteen samples of gasoline and one kerosene over a temperature range from 5 deg. to 55 deg. cent. (41 deg. to 131 deg. fahr.). These tests showed that kerosenes have a lower fluidity or higher viscosity than water, while gasolines, though varying greatly among themselves are all more fluid than water. This is in agreement with the published data in regard to kerosene; the available information in regard to the viscosity of gasolines is very meager.

It is generally recognized that the gravity test is an uncertain guide to the quality of kerosene or gasoline, if taken by itself without information as to the source of crude oil. This was confirmed by the tests on gasolines, their order when arranged according to densities being quite different than when arranged according to fluidities. A fractional distillation is often used as a substitute or supplement to the gravity test, and this gives valuable information. It requires, however, more complicated

apparatus and greater skill than needed to test fluidity. Furthermore, the close relation between fluidity and vapor pressure, to which attention has been called by E. C. Bingham, points to the conclusion that fluidity may be an extremely good criterion for volatility.

Bingham gives tables for fluidities of various pure chemical compounds over a wide range of temperatures, and these tables were used to compare the fluidities of the thirteen gasolines with those of the aliphatic hydrocarbons. It was found that ordinary commercial gasoline, as now sold for use in automobiles, has a fluidity slightly less than octane. Most of the special gasolines, intended for use in airplane motors, have a fluidity between that of heptane and hexane. The temperature-fluidity curves of these gasolines were nearly straight and parallel, so that the order of the different gasolines, arranged according to fluidity, would be nearly independent of the temperature considered. It is suggested that the specification of fluidity at two temperatures might serve to define a desired grade of gasoline. (Abstract from Bureau of Standards Technologic Paper No. 125)

The Constitution and Microstructure of Silica Brick and Changes Involved Through Repeated Burnings at High Temperatures, R. Insley. With the coöperation of many of the principal American manufacturers of silica brick, petrographic and microscopic studies were made of the raw quartzite, the finished brick, and brick which had received repeated burns by actual use in kilns, coke ovens, etc., for the purpose of determining the original constitution and also components of silica brick stable under conditions of repeated burning such as it would undergo in the industries. Test cubes were also prepared in the laboratory of the Bureau of Standards according to a standard commercial mix and burned at 50-deg. intervals from 1200 deg. to 1500 deg. cent. in order to trace out the mineralogical structure changes with increasing temperature.

Quartz, critobalite, tridymite, pseudo-wollastonite (α — $CaO.SiO_2$), and glass are found to be present in silica brick. Pseudo-wollastonite and glass are never present in anything but small amounts. The proportions of the other constituents vary according to the heat treatment undergone.

Microscopical quantitative analyses of the relative proportions of the three predominant minerals were made of each brick examined. These analyses show that the longer a brick is burned at high temperatures but below 1470 deg. cent., the greater will be the amount of tridymite present.

Silica brick are usually found to have a porphyritic-like structure made up of phenocrysts and groundmass. This structure is not due to any chemical or physical action which takes place during the heating or cooling of the brick but is caused by the method of grinding the raw material, the phenocrysts being the coarsely ground pieces while the ground mass is made up of finely ground material and rock flour.

Microscopic examination shows that the first inversion is from quartz to cristobalite and begins in the groundmass. The material which is broken up in the phenocrysts by shattering due to expansion on heating is then transformed into cristobalite and rims of cristobalite form around the phenocrysts similar in appearance to the reaction rims seen around minerals in natural rocks. After long heating tridymite begins to appear in the groundmass. The crystals are at first very small and rather poorly developed but increase in size with successive burnings. Tridymite is usually present at wedge-shaped and more complicated interpenetration twins. In reburned brick the quartz phenocrysts are occasionally entirely transformed to cristobalite and sometimes even tridymite crystallites begin to appear in the phenocrysts.

The lime added in the grinding of the raw materials does not appear to aid in the bonding of the brick by the compounds which it forms but rather by hastening the inversion of the silica through its fluxing action. Most of the bonding action seems to be due to the interlocking of the cristobalite and tridymite crystals. Any glass present aids but little in the bonding.

Permanent expansion is caused by the inversion of quartz to cristobalite and tridymite. A large proportion of tridymite is desirable in silica brick since it has the larger permanent expansion and subsequent buckling of the furnace walls is reduced to a minimum.

The investigation has verified the prediction of Fenner: that with a comparatively small amount of flux quartz inverts to cristobalite, then to tridymite at temperatures where cristobalite is the unstable and tridymite is the stable modification. In the case of every brick examined cristobalite was the first inversion product to form, whether the conditions had been such as to promote much or little inversion. Moreover, the final inversion product reached after many reburnings to the temperature range where it was the stable modification, resulted invariably in the formation of tridymite. (Extended abstract from Bureau of Standards Technologic Paper No. 124)

The Ultra-Violet and Visible Transmission of Eye-Protective Glasses, K. S. Gibson and H. J. McNicholas. Many glasses are on the market and extensively advertised to protect the eyes from injurious radiant energy. Unfortunately, but little authoritative information concerning the properties of these glasses has been available. The public and even oculists and physicians have had little to guide them in selecting such glasses except the claims of makers and agents. One purpose of such glasses is to absorb the injurious radiant energy which is emitted along with the light from certain lamps as well as from welding arcs and industrial furnaces, while transmitting sufficient light for vision. They thus act as filters. Another purpose in certain cases may be to absorb part of the light so as to reduce a blinding brilliance. Glasses of different types are required for different needs. The degree to which these glasses actually fulfill their avowed purpose can only be determined by measurements of their "transmission" (i.e., the ratio of transmitted energy to the energy falling on them) for the various forms of radiant energy in question. The Bureau of Standards has made such measurements on a great number of glasses now on the American market and the results are published in this paper. (Abstract from Technologic Papers of the Bureau of Standards, No. 119)

ENGINEERING MATERIALS

Fiber. Fiber was originally developed as an insulating material and as such was widely adopted in electrical work. Since then, however, it has also found wide applications in other fields, both of mechanical equipment and such non-mechanical uses as baskets, barrels, boxes, etc.

It possesses most of the properties of the flexible and semi-flexible materials and at the same time some of the desirable qualities of hard materials and metals, and as a material of construction may be considered as an intermediate between the two groups.

There are three kinds of fiber in general use, viz., two kind of vulcanized fiber—known as hard and flexible, and horn fiber. Vulcanized fiber is made by treating specially prepared vegetable fiber (usually cotton) with strong chemical reagents, afte which it is manipulated with heavy machinery to produce th two commercial forms. During the passage of the so-calle paper through the chemical bath the cellulose base is hydrolize and the surface is gelatinized to such an extent that on bein passed through the laminating machines a homogeneous produ is produced. Horn fiber is somewhat similar to vulcaniz fiber but has hemp twine (instead of cotton as in vulcanized fibe as its base is not chemically treated. The hydrating effect pr duced by chemical action in the case of vulcanized fiber is a proximated in the case of horn fiber by prolonged heating. is not quite as hard and can not be made as thick as vulcaniz fiber and has, therefore, a more limited field of application.

Vulcanized fiber is made in two forms, hard and flexible; latter being restricted to such uses as pump valves, washers a gaskets. Fiber should be clearly distinguished from such insul ing materials as bakelite, condensite and others which have ma properties similar to those of fiber but are not fiber.

Vulcanized fiber possesses great strength, elasticity and du bility. Its tensile strength varies from 10,000 to 20,000 lb. per sq. in. (as compared with 3000 to 6000 lb. for leather). Its

resistance to compression varies from 40,000 to 60,000 lb. per sq. in. (for wood it varies from 3000 to 11,000 lb.). Its resistance to shearing varies from 9000 to 13,000 lb. per sq. in. (compared to wood, with the grain, 225 to 906 lb., to aluminum casting 12,000 and to aluminum forgings 16,000 lb.). There is no clearly defined elastic limit, but it approximates 4000 lb., and there is no permanent set even at rupture point. The specific gravity is about 1.3, varying from 1.2 to 1.5 (sp. g. of pure aluminum in a cast state is 2.58; of cork, 0.24; of wood, 0.35 to 1.33). It possesses the strength and density of a metal, yet is elastic and nearly as light as hardwood. A square foot of 1/8-in. fiber weighs about 7/8 lb., and the same area of 1-in. stock about 7 lb.; i.e., about 20 cu. in. to the pound. Fiber is usually sold by weight and the present article gives the average weights of standard sheets.

Vulcanized fiber is insoluble in all the ordinary solvents and is not affected by immersion in alcohol, ammonia, benzine or any of the animal, vegetable or mineral oils. It absorbs water freely and swells when wet but is not otherwise injured.

When heated, fiber does not melt or soften, but at a high temperature it chars and loses its elasticity. Vulcanized fiber is not brittle and will stand a great amount of pounding and rough usage. It can be machined and will take a fine polish but cannot be molded.

The original article describes and illustrates many applications (mechanical and electrical) of this material. (*Raw Material*, vol. 1, no. 1, new series, March 1919, pp. 115-120, illustrated, *d*)

New Methods of Etching Show Hitherto Undiscovered Characteristics of Rail Steel

Rail Steel. Abstract of a report of an investigation carried out under the direction of the Rail Committee of the American Railway Engineering Association, the following points of which are of special interest:

The discovery of the value of deep etching with strong acid is bringing out hitherto unrecognized defects in the interior of the rail head. The Altoona Laboratory of the Pennsylvania Railroad has for some time suspected that chemical analyses of samples from different parts of the cross-section of the rail do not give sufficient information as to its quality. Further, the usual micrographic etching solutions employed have proved unsatisfactory and definite results have been secured only when the specimens were etched for two hours in a mixture consisting of nine parts hydrochloric acid, three parts sulphuric acid and one part water, kept at 200 deg. fahr. This brought out a remarkable number of longitudinal, transverse and irregular marks or depressions, and these marks, representing streaks of more soluble materials, proved the existence of serious non-homogeneity, which hitherto could not be discovered otherwise.

In a rail that had never been in service the deep etching with strong mineral acid mixtures brought out indications of irregularity of structure, whereas picric acid etching has failed to develop anything unusual. In this connection an observation is reported by J. B. Young, chemist of the Philadelphia and Reading Railroad, whose tests indicate the likelihood that flaws and cracks may exist in new rails which have been subjected to no strains except those developed in the rolling.

The second point brought out by the research of the Rail Committee is that statistics prove that about all transverse fissures occur in rails rolled directly from the ingot, while rails from reheated blooms virtually never fail in this way. If true, this would prove that defects of the ingot rather than excessive stresses are responsible for transverse fissures. As an editorial in *Engineering News-Record* (March 27, 1919, p. 599) remarks, it may be deduced from these data that there seems to be more promise in metallurgical studies of rail steel and examination of furnace and mill conditions than in the study of track service.

Tests of rails by a magnetic tester to detect internal flaws were made by Dr. P. H. Dudley of the New York Central Lines. He gives no details as to results obtained, but states that the leakage curves of rails obtained with this apparatus furnish much information about the physical properties in rails and about the disturbance of the metal by the gag press employed in straightening it.

For acceptance tests on the Pennsylvania Railroad rails are subjected to a press bending test in addition to the regular drop test. The press is in a hydraulic machine operated by an intensifier standing alongside, and capable of exerting a pressure of 378 tons. The main ram is 16 in. in diameter and has a 12-in. stroke. The machine weighs 11 tons. The supports for the rail, under the pressure ram, may be set at various spacings; tests have been made with supports 24 in. to 51 in. apart. A hydraulic pressure indicator records on a drum turned by a connection with the main ram, so that an autographic diagram is produced.

Deflections at ultimate load of rail specimens bent in this machine are found to be an indication of the ductility of the material, just as well as is the elongation in the drop test of the rail. It is also believed that the deflection is in a measure an indication of the toughness of the rail, or rather its capacity to resist shock.

Tests made up with the head down (in tension) gave more satisfactory and uniform results than those made with the head up. In the former, breaks were obtained in nearly all cases, while with the head up the breaks were apt to be branching or irregular. Furthermore, the tests made with different lengths of span of the rail showed closer agreement between the test results and theoretical curves, for the tests with head down than those with head up.

One of the striking results of tests with the bending machine brought out in a report on the subject submitted by W. C. Cushing, chairman of the subcommittee on the quick-bend tests, is the distinct superiority in quality of the rails produced by one mill as compared with those of another. A large number of tests of 130-lb. rails from three mills, plotted to show elastic limit as ordinates and ultimate deflection as abscissæ, placed the rails from one of the three mills in a group distinctly above and to the right of the groups representing the other two mills. This comparison shows greater ductility and strength, on the average, for the rails of the first mill, though all were rolled to the same specification and the same section and weight.

In another experiment, a rail that failed in the bend test at a small deflection—in other words, was brittle—was retested after annealing, and the deflection was increased more than four times, indicating a curing of the brittleness by the heat treatment. (*Engineering News-Record*, vol. 82, no. 13, March 27, 1919, pp. 610-611, *eA*)

FOUNDRY

Necessary Properties of Molding Sand and Their Determination

The Practical Analysis of Molding Sand, P. Albert Hayes. The paper discusses sieve tests and the methods of selecting sand, and attempts to give a definition of the best usable sand. Molding sand must satisfy the three major requirements of rigidity, permeability and refractoriness, which the author further subdivides as follows:

Rigidity:

a Bond of clay; *b* Size, and shape of grain.

Permeability:

a Porosity; *b* Quantity of clay; *c* Size and shape of grain.

Refractoriness:

a Quality of clay; *b* Quantity of clay; *c* Size of grain.

Rigidity and Bond. The ability of molding sand to resist strain after forming is dependent on the shape of the sand grains and also bears a very close relation to the bond of the sand. Sharp, angular and flat-sided grains interlock and form a stronger mold than rounded grains; but, on the other hand, such interlocking reduces the freedom of escape of gases and also gives a less evenly packed mold than do round grains. Hence rigidity should be secured by the bond of the clay rather than by dependence on sharp sand.

The power of clay to keep the grains of sand together depends on its content of fatty or sticky clay. The necessity of sufficient bond in worked floor sand is often neglected. The fatness of

the clay is destroyed by contact with the hot iron in the molds and care should be exercised in shaking out the castings to see that the minimum of burned sand is returned to the pile.

Porosity and Permeability. The proper venting of sand depends both on the porosity and permeability of the sand, the former referring to the spaces existing between individual grains of sand and the latter to the shortest linear distance through the pore spaces between the grains from one side of a unit volume of sand to the other. In this connection the tempering water and amount of clay are important since a large clay content will tend to fill the pore spaces and diminish the venting qualities, while water tends to reduce the permeability. Experiments indicate that 4 per cent of water is the average requirement to give maximum strength, and increasing the tempering water 50 per cent decreases the strength 35 per cent. In this connection, the original article cites tests made from several floors on which the very much lower temperatures and thereby form fluxing materials. As a result such alkali silicates may reduce the fusing point of the mixture so that cutting of the mold takes place with excessive loss of sand and poor casting surfaces. It may also cause sintering and sticking of the material to the mold. A good check on this factor is the determination of the amount of sand used per ton of castings of a given classification. This figure varies a great deal in foundries showing that either the sand is deficient or the practice is poor.

The grain size of the sand bears a relation to the size of the casting poured, a small casting taking a finer sand than a large one.

The writer recommends the use of the so-called rational analysis which would cover the percentage of clay, quartz and feldspar, and the relative fatness or bond of the clay together with a sizing test (cp. Table 1).

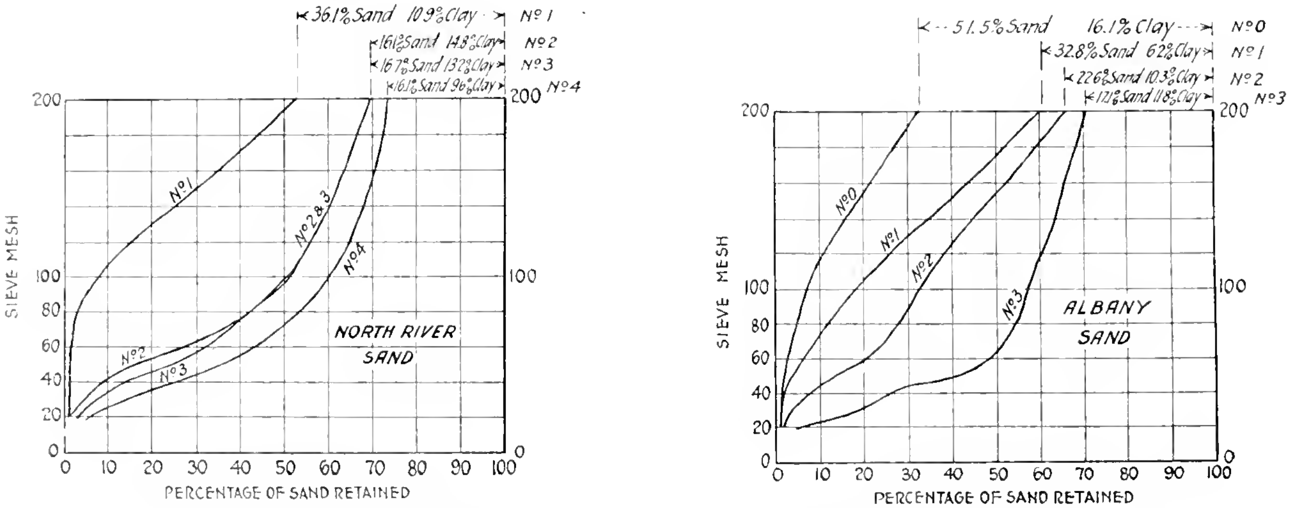

FIG. 1 GRAPHICAL STUDY OF THE RELATIVE GRAIN SIZE OF VARIOUS SANDS WHICH FACILITATES THE SELECTION OF FOUNDRY MOLDING SAND FOR THE PARTICULAR WORK IN HAND

same sand was used and the same general class of work was molded. All the sand was mixed by a sand cutter, but each individual molder tempered his own sand. The results have shown that the water content was very irregular.

Refractoriness. Refractoriness affects the ease with which the mold is broken down after use and the damaged sand is reclaimed.

TABLE 1 ANALYSIS OF SANDS, DRY BASIS

Moisture as received.	10.5	6.5	9.1	7.3	8.6	8.2	7.8	10.0

The molding material consists of silica sand which is practically infusible, while fat clay and aluminum silicate are unchanged by the heat of molten iron except at the inner mold surface, and residual mica and silicates of the alkalies fuse at

The sieve test indicates the size of the casting for which the sand is suitable, while the other data will show the sand that will give the most rigid mold with greatest permeability and ability to stand the cutting action of the hot iron.

The accompanying curves (Fig. 1) are found by plotting the percentage of sand that will be retained by a given mesh. The perfect sand would be a straight sand parallel with the abscissa, and the nearer this condition is approached, the better the sand. Practically a sand never gains the ideal, but the graph affords very ready comparison. Many founders can grade sand to a certain extent by feel, but the writer has seen many instances of false judgment on the part of experienced men. For instance, the same sample of sand presented at two different times was graded as 1 and 2. Reference to the curves gives explanation, as the No. 1 and No. 2 sands are very similar; but the decision as rendered determined the use on certain floors. (*The Iron Age*, vol. 103, no. 12, March 20, 1919, pp. 739-741, 1 fig., *p*)

FUELS AND FIRING

STOKERS TO BURN COKE BREEZE. Description of mechanical stokers designed to burn coke breeze. These stokers contain a nonsifting grate which the designer (Joseph Harrington, Mem.Am. Soc.M.E.) emphasizes as a feature fundamentally new.

The stoker consists of cast-iron side frames carrying the driving gear, hopper, front shaft and feed gate. The grate bars overlap, giving a tortuous air passage and preventing the falling of fine fuel into the air compartment below. The bars are made of gray iron and the overlapping is secured by causing one bar to project under the overhanging part of another.

The following conditions were considered as necessary to be met before forced draft could be successfully used with coke breeze:

1 The stoker must allow the fuel to remain quiet during the

combustion period in order to avoid the formation of clinkers that cause any disturbance of the fuel bed when the ash content is in a plastic condition.

2 To avoid the accumulation of refuse in the furnace and consequent fouling of the grate surface, it must be discharged as formed, so that the ash remaining on any unit section of the grate is that which results from the burning of a single unit of fuel.

3 There must be no air spaces that are not periodically and completely cleaned by the automatic operation of the adjacent parts and disengagement of clinker which may have entered the air spaces during the previous passage through the furnace.

4 Inasmuch as the fuel bed does not require the same volume or pressure of air throughout its extent, the stoker of the future must be divided into compartments in such a manner that the air pressure and volume in each compartment are suited to the requirements of the fuel passing over the compartment.

5 To avoid the wasteful use of steam-driven auxiliaries, the stoker must be readily converted to the natural draft type during the low-load periods.

6 Parts subjected to the heat and fusing action of direct fuel contact must be readily replaceable and subjected to no mechanical stress other than its own support and the support of its portion of the fuel bed. (*Iron Age*, vol. 103, no. 13, March 27, 1919, pp. 816-817, 3 figs., *d*)

New Fuel Developed by Submarine Defense Association

Colloidal Fuel. Two articles describing experiments on colloidal fuels developed under the auspices of the Submarine Defense Association. This association was organized in June 1917 by companies representing the shipping and marine insurance interests of this and other countries to assist in developing effective anti-submarine measures and had its offices at 141 Broadway, New York City.

According to the report pulverized coal can be successfully held in suspension in fuel oil so that the colloidal liquid flows freely through pipes, preheaters and burners equipped to burn fuel oil. Months after mixing the composites showed little or no deposit. A "fixateur" which comprises about 1 per cent or 20 lb. per ton acts to stabilize the particles of pulverized coal in the oil. The fixateur and fixated oil are readily made and may be shipped anywhere. On burning, the combustion is so complete that with fair coal there is no slag and very little ash left.

Regarding the saving of cost involved in the use of this fuel, the report of the association states that, for example, with coal at $4 per ton and oil at $4 per 50-gal. bbl. the saving is $2 per ton. With coal at $5 per ton and oil at $7 per bbl. the saving is close to $6 per ton.

An interesting feature of the new development is that plants and railroads may buy from refineries any grade of colloidal fuel they desire to the prescription wanted, or they may obtain the appropriate fixated oil and make a final composition themselves. No change in oil-storage or burning equipment is required.

Another development is represented by colloidal fuel made with pressure-still residuals which hitherto have been quite neglected. From these residuals a fuel is prepared so low in sulphur that it is expected to command a premium for making higher-grade alloy steels.

A further research was started in blending petroleum oils and coal tars to see if it was practicable to stabilize the mixture so that free coke and asphaltic substances would not settle out but would produce a stable liquid fuel that could be shipped, piped and stored. The quest was well worth while because could it succeed one might so create annually here and in England up to 20,000,000 bbl. of superior liquid fuel without an increase in oil-well production. Success is now confirmed. Thus countries without oil like Australia, France, Italy and England may themselves produce over half of the substances to make liquid fuel, and as the gas-house and coke-oven tars are usually cheaper than fuel oil they will average down the cost of oil in the composite.

The experiments in making colloidal fuel were conducted at the Brooklyn plant of the Standard Oil Company. No information is given as to the nature of the fixateur besides saying that it is a heavy, black, pasty substance of the consistency of axle grease.

The fixateur, to the amount of 1 per cent of the finished product, is placed on the top screen of four horizontal screens which extend through the entire diameter of a tank, about 20 ft. high and 12 ft. diameter. The oil is entered through the top of the tank and seeps through the fixateur. The lower screens catch that part of it which oozes through the first screen, thereby holding it up where more oil can encompass it. When the oil has thus been fixated, it is introduced by pumps into the mill, which is a cylindrical tank about 2 ft. high and 3 ft. in diameter, inside of which are the mixers, consisting of arms with balls upon the ends. After the fixated oil and coal dust have been thoroughly compounded, the new mixture is pumped into storage tanks, ready to be forced into the burners.

Different grades of coal have been experimented with, ranging in ash content up to 25 per cent. An especially good carbon material has proved to be a coke containing, it is stated, 98 per cent carbon, no ash and no sulphur. The mobile paste, which is about half oil and half coal, is said to develop the largest number of heat units per unit volume of any proportion. With higher coal percentage the total B.t.u. content per gallon diminishes gradually.

Though the first experiments were conducted for marine purposes during the submarine menace, it is believed that varied uses will be found on land as well as sea in many peace-time pursuits. It is thought that colloidal fuel will be the fourth major fuel, on a par with existing solid, liquid and gaseous burning substances. Experiments are soon to be conducted in steel plants. One advantage claimed is that waste coal will be utilized with profit by the new process. (*Iron Age*, vol. 103, no. 13, March 27, 1919, p. 824, *eA*)

HOISTING MACHINERY

Gearless Tractor Elevator and Its Safety Appliances

Gearless Tractor Elevator, R. H. Whitehead. Description of an installation using the 1:1 gearless tractor-type elevator machine.

The particular feature that characterizes this type of installation is that the driving sheave and brake wheel are pressed directly on the armature shaft of the motor and hence rotate at the motor speed. The motor, therefore, must be built for very slow speeds and generally has six or eight poles wound with shunt field only. The armature is series-wound with rectangular conductors to get the largest amount of copper into the armature slots. The result is that the dimensions of the motor are several times larger than those of a machine of the same power built for a greater speed.

The matter of slippage is taken care of in the following way. The counterweight, which includes the counterweight buffer, is adjusted so that it equals the total weight of the car and sling, plus 40 per cent of the car load. Thus, for a duty of 2500 lb. the counterweight would weigh 1000 lb. more than the car and sling. With compensation as obtained by compensating ropes (Figs. 2 and 3), the maximum difference between the tension on the counterweight and the car side of the hoisting rope is 1500 lb. As the total load on both sides exceeds 16,000 lb. and as slippage does not occur until the load on one side is twice that on the other, the traction is positive; in fact, as positive as if the ropes were wound on a spirally grooved drum, which in this case would be impossible on account of the large amount of rope required due to the high rise.

The hoisting ropes are so adjusted that if the car should overrun the bottom landing the counterweights will not run into the overhead work. If either the car or the counterweight bottoms in the pit, the traction between the driving sheaves and ropes is lost, so that even if the machine continues to run, neither the car nor counterweights can be drawn into overhead work. This makes this type of machine very safe.

Compensating ropes compensate for the variation in the net load on the driving sheaves due to the shifting of the weight of the hoisting ropes from one side to the other which occurs during motion of the car up and down the hoistway. The weight of the

compensating ropes must be such per foot that they will with the electric cables leading to the car compensate for the net shifting of the load due to the weight of the hoisting ropes regardless of the position of the car in the hoistway. In addition to this a special oilspring buffer (discussed in detail and illustrated in the original article) is placed in the hoistway under the car and counterweights to assist in bringing them to rest in case the car overtravels the top or bottom landings.

An elaborate system of safety devices is provided, summed up in the following manner in the original article:

1 Automatic return of the car switch to an off position.

2 The automatic stopping switch gradually brings the car to a stop as the top or bottom landings are approached.

3 The hatchway limit switches operate if the car continues to move after the automatic stopping switch opens the reversing switches.

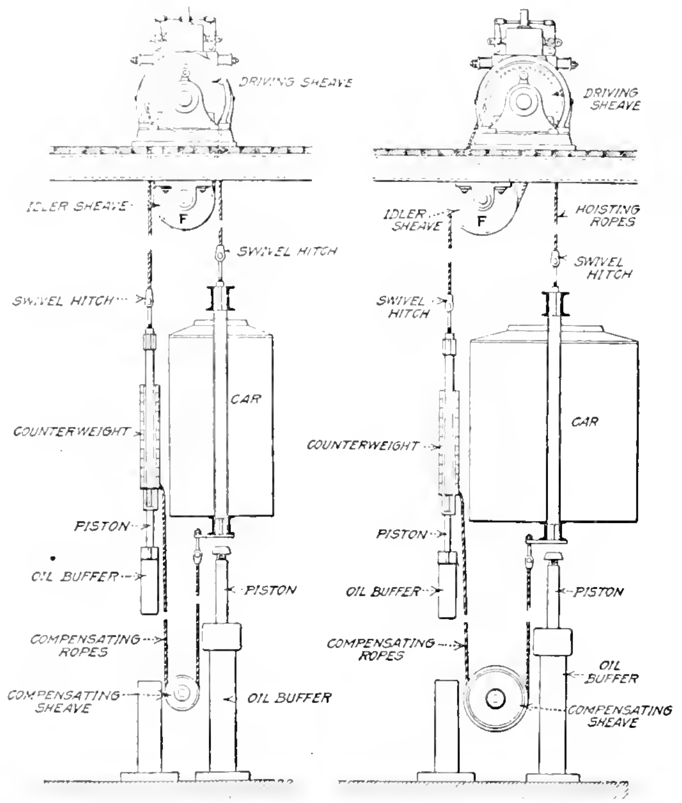

Fig. 2 Installation where Driving Sheave Spans Half the Car Width

Fig. 3 Installation where Driving Sheave does not Span Half the Car Width

4 The switch operated by the centrifugal governor stops the car in case of overspeeding, by causing a light retarding force to be applied between the car-safety jaws and rails and opening the main potential switch.

5 The oil buffers are capable of stopping the car or counterweight at 50 per cent excess speed without discomfort to passengers.

6 After the car or counterweight strikes the bumpers, the traction between the hoisting cables and driving sheave is either lost or greatly reduced.

7 Overtravel beyond the top terminal landing lifts the compensating sheaves and housing, and this in turn helps to decrease the traction and also operates a switch to stop the motor.

8 Opening of the car-safety switch stops the motor and applies a light retarding force between the car-safety jaws and rails, thus stopping the car.

9 For high-lift elevators a mechanical retarding and latching device is provided to stop the car from overrun beyond the top-terminal landing.

10 Breaking of the hoisting ropes causes the application of a heavy retarding force on the car and counterweight safeties. (*Power*, vol. 49, no. 13, April 1, 1919, pp. 474-478, 9 figs., *d*)

HYDRAULICS

Values of n in Kutter's Formula for Different Channel Conditions, C. E. Ramser. Experiments were made to determine the value of n in Kutter's formula on five courses of the South Forked Deer River, between Jackson and Roberts, Tenn.

The channel along these courses varied from one newly dredged and in excellent condition to a very crooked course of the old river in very bad condition, and Table 2 gives the values of n obtained for each of the courses for stages ranging from low to high.

The lowest values of n were obtained for the course of channel near Roberts (Table 2) where they were taken at periods from

TABLE 2 VALUES OF n IN KUTTER'S FORMULA FOR DIFFERENT CHANNEL CONDITIONS

Name or type of channel	Minimum value of n	Maximum value of n
Roberts Channel (straight)..........	0.0240	0.0255
Jackson Channel (straight)..........	0.0310	0.0420
Irregular Dredged Channel	0.0367	0.0455
Old Straight River Channel	0.0500	0.0620
Old Crooked River Channel.........	0.1400	0.1620

four to six months after the dredging of the channel has been completed. These low values may be attributed to the comparatively smooth and regular side slopes and bottom, the uniformity of cross-section and the freedom from curve or obstructions in the channel.

The effect of roughness and irregularities is revealed in the results obtained for the course near Jackson. Although the channel was practically free from vegetation or obstructions of any sort, yet the values of n are considerably higher than those obtained for the course near Roberts. The irregularities in the lower portion of this channel were left at the time of construction, the bottom and sides of the channel never having been smoothed properly.

Still higher figures are obtained on the old straight river channel where the course is fairly straight but the cross-section variable, side slopes irregular, bottom irregular with deep holes and, what is most important, the sides are covered with trees, roots and vines and subject to caving. Here the value of n is roughly three times as high as in the section of channel near Roberts.

Finally the highest values for n were obtained in the old crooked river channel where the side slopes are very irregular, the bottom likewise very irregular and full of holes. There are many roots, trees and bushes on side slopes and many logs, large trees and other drift on bottom, in addition to which trees are continually falling into the channel due to caving banks. Furthermore, the course of the channel itself is very crooked and is made up of four distinct curves.

A comparison between the figures for the old straight river channel and the old crooked river channel is particularly instructive, since the conditions of flow except for the difference in shape of channel are rather similar and the difference in values of n is apparently due to this difference in the character of the course of the channel. (*Engineering News-Record*, vol. 82, no. 11, March 13, 1919, pp. 522-523, 5 figs., *et*)

INTERNAL-COMBUSTION ENGINEERING

Port Design for Two-Cycle Oil Engines. Discussion of a subject on which comparatively little has been published in the English language. The writer mainly considers the so-called semi-Diesel type of crude-oil engines.

The article, which is not suitable for abstracting, discusses the design of the inlet port, transfer port, and exhaust port, and gives formulæ therefor.

The writer calls attention to the fact that the designer of semi-Diesel engines should fully appreciate the necessity of getting int

the cylinder for scavenging purposes the largest amount of air possible. Not all of the incoming air remains in the cylinder and a portion of it may be driven out through the exhaust ports, allowing a corresponding amount of exhaust gas to remain in the cylinder. This loss may be taken care of in some manner and, for example, in the marine Diesel engines where scavenging air is furnished by a separate pump the displacement of the pump piston is made approximately $1\frac{1}{2}$ times that of the power piston. The design of the deflector on the end of the piston is very important in getting this air into the cylinder with the least possible loss. By a mere change in the shape of this deflector the writer claims to have seen the developed horsepower increased 10 to 20 per cent. Indicator cards of various engines are given with interesting comments on their showing. (*The Gas Engine,* vol. 21, no. 2, Feb. 1919, pp. 37-42, 5 figs., *et*)

New British Carburetor with Modified Venturi Tube

Cox "Atmos" Carburetor. Description of a new carburetor of British manufacture. The commanding feature of the device is a special construction of what has come to be known as the venturi tube, well illustrated in Fig. 4. It is claimed that in the usual venturi tube as the speed of the engine and hence of the air increases, the depression about the jet also increases, with the result that a relatively greater portion of gasoline than is necessary flows through the jet and the mixture becomes too rich unless special measures are provided to correct this fault.

The following explains how this difficulty is handled in the Cox carburetor. If air be drawn through the venturi tube, there comes into play at the walls of the narrow throat a fall in pressure, as at 1 in Fig. 4. The depression in this region is believed to be in strict proportion to the volume of fluid passing through the venturi. If, therefore, the jet of a carburetor be placed in a small choke tube entering the narrow throat of a venturi, then as the volume of air passing through is increased so will the depression on the jet increase in proportion. In other words, it is claimed that with such an arrangement if the mixture be set right at one point, it will remain correct over the usable range of variation in volume per unit of time demanded by the different speeds of the engine. It should be borne in mind, however, that the conditions described held good only so long as the venturi preserves its shape, or, in effect, so long as the barrel throttle is wide open.

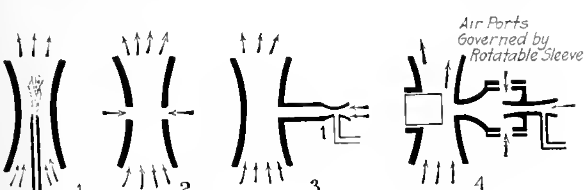

Fig. 4 Diagrams Illustrating the Principle of the Cox Carburetor

At the walls of the throat of a venturi tube there is also a region of depression, and if holes be drilled at this point (2, Fig. 4) a flow will be induced through the apertures, as indicated by the horizontal arrows. No. 3 a diagram of the carburetor at full throttle opening is shown at 3, Fig. 4. From the throat of the main venturi a pipe runs to a small subsidiary choke tube surrounding the jet. The operation with partly open throttle is shown at 4, Fig. 4. Air ports open as the throttle closes in order to prevent too great a fall of air pressure around the jet. For the sake of simplicity a piston throttle is shown in place of the barrel-type throttle actually employed.

In the Cox carburetor (Fig. 5) the middle portion of the main venturi tube is formed in the throttle barrel itself, and with partly closed throttle, therefore, the conditions of the perfect venturi tube no longer obtain, the flow of the air becoming distorted. In consequence of this, with the partly closed throttle there is a reduction of pressure in the region of the branch choke tube and the jet will be forced to deliver a disproportionately great amount of gasoline, so that the mixture will become too rich. This difficulty is overcome by the introduction of air ports in the subsidiary choke tube on the engine side of the jet. These ports are gradually opened and closed by a sleeve attached to the throttle barrel in such a way that closing the throttle opens the air ports.

Attention is called also to the consideration of the float chamber (Fig. 5). The float rises and falls upon a fixed central guide. It is separated from the needle valve and, therefore, vibration is less likely to temporarily upset the gasoline level. The needle valve is carried within a separate cylindrical duct and is operated by a single fork-ended balance-weighted lever.

A particularly important feature of the float-chamber design is the provision made to trap dirt or water. The delivery from the needle-valve duct is high up in the chamber, and the gasoline has to rise to the top of the gauze filter cylinder before it can overflow to the float chamber. At the bottom of the needle-valve duct is a passage leading to a trap chamber beneath the main float chamber. Any water or grit issuing past the needle valve falls by

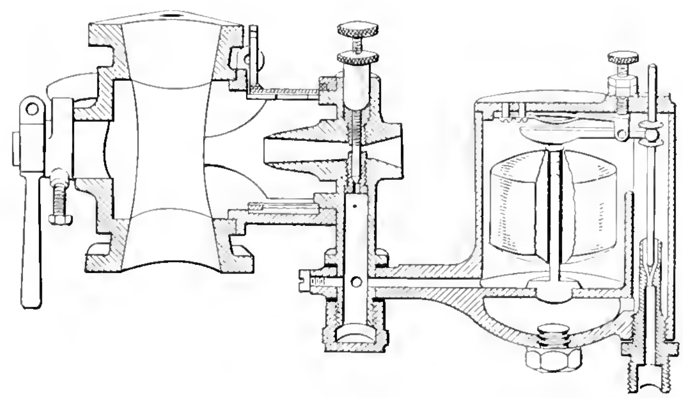

Fig. 5 Section in Perspective of the Cox Carburetor

reason of its greater specific gravity into this trap chamber, whence it can be drawn out from time to time through the orifice of a detachable plug. (*The Autocar,* vol. 62, no. 1221, March 15, 1919, pp. 358-360, 4 figs., *d*)

Striking Results of Tests on Liberty-12 Engine

Outlet Water Temperatures and Engine Efficiency. Data of tests (hitherto confidential) on a standard Liberty-12 engine, model A, the purpose of which was to determine how the various outlet water temperatures affect the power curve of the engine. In general, it was found that the power increases as the cooling-water temperature decreases to a point of about 100 deg. fahr. It will be noted, however, that at 90 deg. the power again begins to drop off slightly at the higher speeds. Also, the power decreases considerably with an extreme increase in temperature. At about 200 deg. fahr. the power is only 417 hp., while at 90 deg. fahr. it is 436 hp.

TABLE 3 GASOLINE CONSUMPTION OF LIBERTY-12 ENGINE AT VARIOUS OUTLET WATER TEMPERATURES

Outlet water temperature, deg. fahr.	200	170	150	130	110	90
Rev. per. min.	1600	1600	1600	1600	1600	1600
Average hp	382	387	388	397	400	403
Lb. per hour	197.5	200	204.5	206	205.5	197.5
Gal. per hour	33.5	33.9	34.7	34.9	34.8	33.5
Lb. per hp-hr	0.518	0.518	0.527	0.520	0.516	0.490

This is well illustrated in the curves in Fig. 6. Because of the fact that the actual data of the tests are reported only in a publication not generally available, those in Table 3 are reprinted here. No information is available as to the other features of operation of the plant. Thus, for example, it is not stated whether preigni-

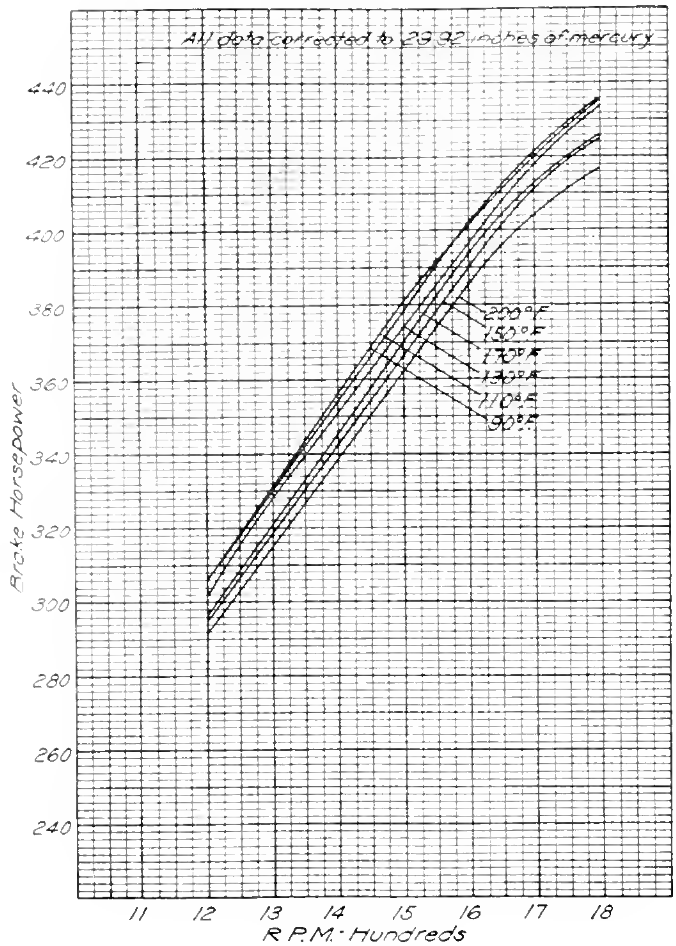

FIG. 6 POWER CURVES OF STANDARD LIBERTY-12 AT VARIOUS OUTLET WATER TEMPERATURES

tion occurred at the higher outlet water temperatures. (*Technical Orders, Technical Division, Air Service*, no. 4, Jan. 1919, pp. 15-17, *e*. Secret publication, present abstract being made by special courtesy of the War Department, Air Service Engineering Division.)

Means for Increasing Power Output of Aircraft Engines at High Altitudes

MAINTAINING CONSTANT PRESSURE BETWEEN THE CARBURETORS OF AIR ENGINES REGARDLESS OF THE ALTITUDE, Leslie V. Spencer. It is well known that at high altitudes the power developed by the ordinary internal-combustion engine decreases materially because of the decrease of the oxygen content in the cylinder charge. The Bureau of Standards curve between the pressure and altitude at a temperature of 50 deg. fahr. shown in Fig. 7 illustrates this fact very well. From it, it appears that at 20,000 ft. an engine operates with an intake pressure of approximately half that at ground level, which affects both the proportion of the mixture and the fuel delivery through the nozzle.

In order to overcome this difficulty in the operation engineers have turned to the idea of supercompressing the air sent to the carburetor so as to maintain as nearly as possible the ground-level pressure regardless of the height. Such supercompression has been given various names, of which the present writer recommends the term "supercharging." The function of a supercharging device is, however, not to increase the normal ground-level power up to the limit in altitude for which the supercharger is designed.

In Europe the method apparently most widely used is the turbo-supercompression, a good example of which is represented by the Rateau scheme developed by Professor Rateau in France.

The rotary compressor has been tried in competition with the centrifugal type of compressor by the British at the Royal Aircraft Establishment and has been discarded in favor of the latter. The centrifugal form of compressor, however, has proved the most desirable through having a minimum of working parts, being very compact for a given capacity and being capable of operating satisfactorily at top speed over long periods of time.

As to the methods of driving the compressor, there are three possibilities. It can be direct-connected with the engine just as a magneto, possibly with a gear train to step up the speed of the compressor rotor as shown in Fig. 8.

Also the compressor might be driven by a small steam turbine, the steam being produced by the exhaust-gas heat. The third alternative is to drive the compressor impeller by means of an exhaust-gas turbine receiving its energy directly from the engine exhaust gas.

In England and Italy direct-connected means of drive through an intermediate gear train have been tried, but great difficulty was experienced in coping with the severe stresses developed in the rapidly operating mechanism due to sudden fluctuations in the speed of the engine.

Steam-turbine drive has not been seriously considered because of the obvious complications and it is the exhaust-gas drive that has found the best favor. The exhaust-gas turbine can be connected directly with the exhaust ports of the engine through special manifolds replacing the standard manifolds, so that all the

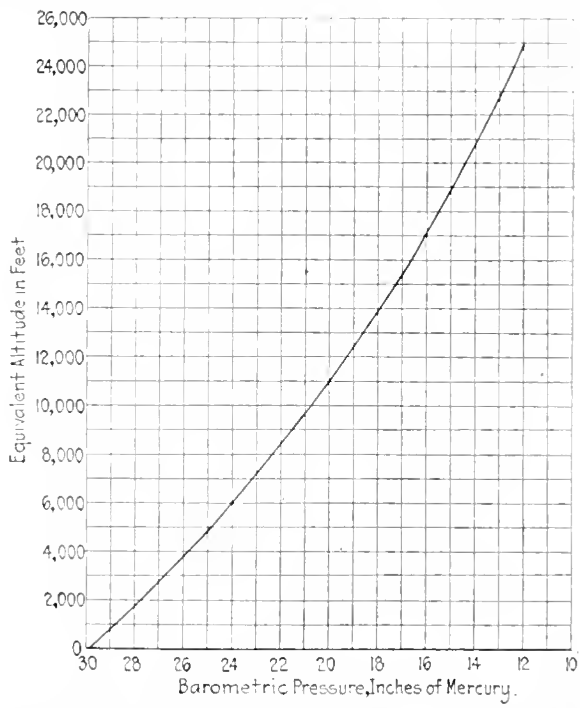

FIG. 7 BUREAU OF STANDARDS CURVE BETWEEN PRESSURE AND ALTITUDE AT TEMPERATURE OF 50 DEG. FAHR.

exhaust must pass through the turbine nozzles and give up its energy to the turbine rotor before being allowed to escape into the atmosphere through the turbine discharge passages.

In the designs which have been experimented with thus far, the turbine rotor and the impeller of the centrifugal compressor are mounted on the same shaft so that the two are in one unit.

The general design of the Rateau supercharger can be seen from Fig. 10. The only difficulty that has been encountered is that of coping with the high temperatures of the exhaust gases, but even this difficulty seems to be close to satisfactory solution.

Around the turbine rotor there is atmospheric pressure while the supercharged engine exhausts at a normal pressure of about 30 in. of mercury corresponding to a normal atmospheric pressure of 15 lb. per sq. in. at sea level. The expansion of the gases from this pressure to that of the atmosphere is sufficient to operate the turbine at high speeds and ordinarily the turbine rotor speeds run up to 25,000 or 30,000 r.p.m.

Experiments with this system indicate that of the energy of combustion the engine and turbo-compressor utilize about 33 per

cent, whereas approximately 45 per cent is lost in the exhaust which finally escapes from the discharge ports of the turbine.

In addition to the work of Professor Rateau and other foreign experimenters a certain amount has been done in America, where at the request of the Government, E. H. Sherbondy and Dr. Sanford A. Moss, Mem.Am.Soc.M.E., have taken up the same problem. The designs evolved in this country will be described in an early issue of MECHANICAL ENGINEERING. (*Aerial Age Weekly*, vol. 9, no. 5, April 14, 1919, pp. 244-246 and 264, 6 figs., *d*)

MATHEMATICS

THE BESSEL-CLIFFORD FUNCTION, G. Greenhill. Writers on stability, statical and dynamical, as of a beam, strut or whirling shaft, are compelled to introduce the Bessel function, to give a complete solution, and the ordinary function is then employed as given in the textbook.

But attention should be directed to a forgotten posthumous note by Clifford, in his Mathematical Papers, 1882, page 346, where

he makes a start with a function, which we may denote after him by $C(x)$, obtained as the sum of all the positive integral k powers of $-x$, $(-x)^k$, divided by the square of the fractorial k, Πk, and thus

$$C(x) = \Sigma(-x)^k.(\Pi k)^2$$

but the exponential function

$$e^{-x} = \Sigma\ (-x)^k\ \Pi k$$

But there is this important difference, that whereas the exponential function never vanishes, the equation $C(x) = 0$ has an infinite number of positive roots.

The nth derivative of $C(x)$ is Clifford's

$$C_n(x) = \Sigma\ (-x)^k/\Pi k\Pi\ (n+k)$$

and the nth integral,

$$\Sigma\ (-x)^{n+k}/\Pi k\Pi\ (n+k)$$

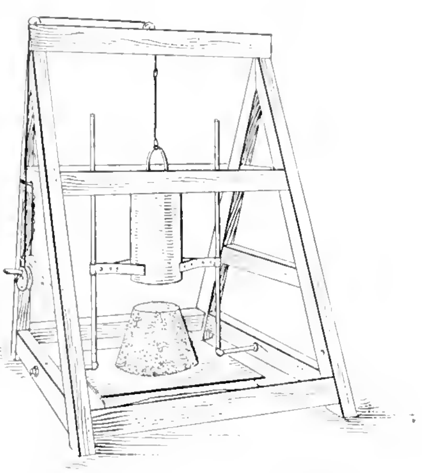

FIG. 11 CONCRETE CONSISTENCY TESTING MACHINE (SHOWING RESULTING CONE FOR CONCRETE WHICH CAN BE SUCCESSFULLY USED IN PRACTICALLY ALL ORDINARY REINFORCED-CONCRETE WORK)

is denoted by $C_{-n}(x)$, so that $C_{-n}(x) = x^n C_n(x)$

Thence the differential equations

(1) $d_x{}^{2n} x^n C_n(x) = C_n(x)$, and

(2) $d_x\,[x^{n+1} d_x C_n(x)] = x^n C_n(x)$

or $x d^2 C_n/dx^2 + (n+1)dC_n/dx - C_n = 0$;

and (3) $J_n(2\sqrt{x}) = x^{0.5n} C_{-n}(x) = x^{0.5n} C_n(x) =$
$x^{0.5n} d^n C(x)/dx^n,\ J_0(2\sqrt{x}) = C(x)$

Take the problem of the uniform chain, hanging vertically and vibrating slightly, investigated on the first page of Bessel Functions, by Gray and Matthews, and again at the end of the book, where the density is taken to vary as the nth power of x the height above the lower end. To realize the experiment it is easier to revolve the chain by hand, bodily in steady motion, and to investigate the permanent shape. When the deviation from the vertical is small, it is proportional to $C(x/l)$, or $C_n(n+1)x/l$, where l is the height of the equivalent conical pendulum, and is the length of the subtangent at the lowest point, the free end of the chain. The plane vibration will be shown in the shadow of the revolving chain thrown on a vertical wall.

In the linear differential equation of the second order, reduced to the canonical form

$$\frac{1}{y}\cdot\frac{d^2y}{dz^2} + \mathrm{I} = 0,$$

where I is called its differential invariant, the solution is given by the Bessel or Clifford function when $\mathrm{I} = kz^m$; or writing it

$$z^2\frac{d^2y}{dz^2} + kz^p y = 0,\ p = m+2,$$

and changing to the variable $x = kz^p/p^2$, the differential equation changes to the (2) above for $C_n(x)$, with $n = -1/p$, as in *Engineering*, page 99, January 24, by Arthur Morley. This is the differential equation required in the investigation of the vertical stability of a mast or tree, and with $m = 1$, $p = 3$, for a vertical wire or uniform rod. Here n is fractional, and in Clifford's definition Πn must be taken to mean $\Gamma(n+1)$, in Gauss' notation. Thus when n is half an odd integer, the Clifford functions are the derivations or integrals of $\sin\ (2\sqrt{x}+a)$.

The Bessel function of real or imaginary argument, denoted by $(b\ e\ r)$ and $(b\ e\ i)$ in Kelvin's notation, are distinguished here by a mere change of sign in the argument x of the Clifford function.

To utilize the elaborate tables computed of the Bessel function, say of argument x, all that is required is a new column alongside of $x = 2\sqrt{z}$, as argument x of the corresponding Clifford function.

If writers on these questions of practical stability, which require the old Bessel function, will introduce these methods of Clifford and his function, they will notice a considerable simplification in their formulæ, and they will give to the writer of the theoretical textbook a lead he will be compelled to follow. (*Engineering*, vol. 107, no. 2776, March 14, 1919, p. 334, *t*)

MEASUREMENTS AND MEASURING APPARATUS

METHOD FOR MEASURING THE CONSISTENCY OF CONCRETE, Herbert A. Davis. Description of a field instrument developed by the Concrete Ship Section, Emergency Fleet Corporation.

The apparatus consists essentially of a metal cylinder (Fig. 11) whose inside surface is perfectly smooth, mounted on metal slides that direct the movement of the cylinder so as to be truly vertical. The cylinder rests on a smooth glass plate supported horizontally and independent of the supports of the cylinder.

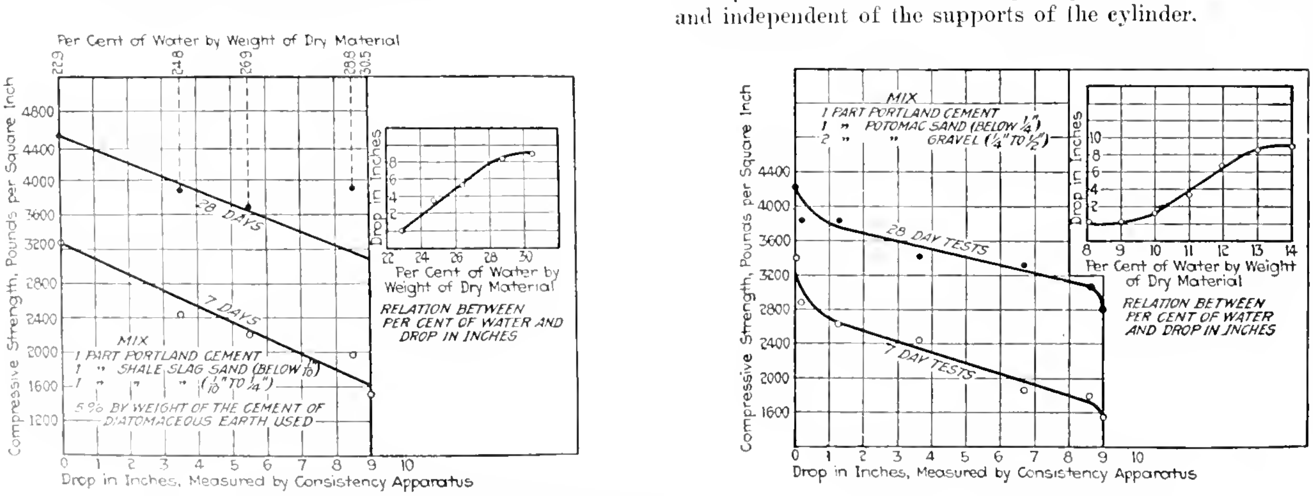

FIG. 12 EFFECT OF WATER ON CONCRETE CONSISTENCY AND DROP AS SHOWN IN TESTING MACHINE

To operate this apparatus the cylinder resting on the glass plate is filled as a mold with the concrete, the top surface is struck off level and the metal cylinder is slowly raised, leaving the concrete unsupported. It was found that this unsupported concrete took various shapes, dependent on the amount of water used in gaging the concrete. Furthermore, over a considerable range it was noted

that the loss in height of the concrete cylinder and the removal of the metal cylinder bore a definite relation to the amount of water used in gaging the concrete.

The diameter of the resulting cone was found to be fairly reliable as a measure of consistency. Typical curves (Fig. 12) showing the relation between compressive strength, the amount of water used and the loss in height of the unsupported concrete cylinder as determined by this apparatus by two different concretes are given in the article, along with certain practical instructions as to the handling of the apparatus. (*Engineering News-Record*, vol. 82, no. 13, March 27, 1919, pp. 603-605, 6 figs, *de*)

MECHANICAL PROCESSES

Manufacture of Pre-Cast Reinforced-Concrete Members for Structural Purposes

Concrete-Molding Plant of the Pennsylvania Railroad Company. Description of a plant, the purpose of which is to manufacture pre-cast reinforced-concrete members for the erection of buildings and construction of bridges, as well as such items (fence posts, telegraph poles, etc.) as lend themselves to production in quantities at a central point. Information is also given on the erection of engine houses involving the use of elements constructed at the plant.

The fundamental idea underlying the erection of this plant is that the building of engine houses and other construction work could be facilitated by concentrating the casting of reinforced-concrete columns, roof girders, beams and similar apparatus at a central point. The site chosen was at Morrisville, Pa., just across the Delaware River from Trenton, N. J. While not exactly at the center of the road requirements for pre-cast concrete products, this site had the advantage of possessing an unlimited supply of sand and gravel peculiarly adapted to the purpose of concrete construction.

The article describes and illustrates the layout of the plant and the method of handling materials, which is of great importance in a plant of this character.

The casting operations proper are carried on in the following manner: The forms are first located on the casting platform and a shed is pushed into position to protect the work. On top of each shed are two tent houses or cupolas over bins into which concrete is deposited from the distributing tower. Leading from these beams to the forms in the building underneath are flexible delivery spouts, each capable of reaching all points within its half of the structure. A gateman stationed in each cupola through which material is being poured, operates valves to the distributing spout as may be required by the operatives on the platform and as is indicated by a system of gong signals.

A very interesting and important feature of these portable casting sheds is the heating system which has been installed in each. These consist of boiler plants located on floors suspended from the roof structure in the corner of each building, and each involving the use of a 20-hp. vertical boiler and a 150-gal. capacity water storage tank. The latter is filled by means of a hose connection to an adjacent hydrant and is of such capacity as to contain about five days' supply at each filling. The radiating coils are mounted on the side and end frames of the building and below the level of the boiler. In order to bring the returns from the heating system back to the boiler plant automatically, steam traps are used in tandem, there being about 20 lb. pressure on the line. The first of these traps collects the condensation and returns it to a point above the level of the boiler from which point the second trap returns the water to its source.

The practice is to protect the work from freezing for a period of 24 hours after pouring. By way of further protection, both from extremes of cold and excessive rates of evaporation in dry weather, large hay-filled mats are placed over newly filled forms until seasoning has advanced to the desired stage.

The articles illustrate the manner in which the various reinforced-concrete elements of construction are cast and assembled. At the outset an attempt was made to cast the roof beams and slabs in complete units, but this was found objectionable because of the unwieldiness of the completed slabs and also because their size precluded the loading of more than three on a single car. This scheme has therefore been abandoned and the plan involving individual roof beams substituted.

The erection of engine houses constructed essentially of pre-cast reinforced members is described in detail. This represents an interesting departure from what might be called standard practice, and the experience that the Pennsylvania Railroad has had is said to be such as to completely justify the experiment. In fact, the first three stalls which the road undertook to erect were set up without a hitch, as have been those since undertaken.

By virtue of the facilities described and the system of engine-house erection that has been adopted, the Pennsylvania Railroad is now in position to complete its program of enlarged engine-house facilities at a rate to which the usual method of casting columns, girders, beams, roof, slabs, etc., in place can bear no comparison; likewise a uniformly dependable quality of construction is insured and is made available at a total cost that not only justifies the plant and facilities that have been provided, but will yield a constantly increasing profit as the road continues to meet the rapidly enlarging demand for concrete structures of whatever type. (*Railway Review*, vol. 64, no. 12, March 22, 1919, pp. 425-432, illustrated, *dA*)

POWER PLANTS

New Patents Concerning Steam-Boiler Firing (Pradel, *Zeitschrift für Dampfkessel und Maschinenbetrieb*, Jan. 17, 1919). This article is the conclusion of a quarterly summary of patents relating to the firing of steam boilers. Descriptions and illustrations of the patents are given.

In the event of failure in the boiler feed pumps, the attendant must close all the boiler dampers. As information regarding pump breakdowns may often take some time to reach the boiler attendant in a large works, and as the closing of all the dampers may take a considerable time, there is a good deal of risk of an explosion occurring. To counteract this a patent (D.R.P. No. 307,490) has been taken out for an arrangement by means of which all the dampers are closed automatically as soon as for any reason the pressure in the feedpipe falls below the normal boiler pressure. Also when the maximum safe pressure is exceeded through failure of the safety valve, the dampers are closed through the pressure in the feedpipe.

Draft-regulating links for steam boiler heating must be occasionally adjusted to the steam pressure. It is also necesary to close the damper when opening the fire door so that no cooling off of the heating surface occurs. The adjustment of the regulating links to the steam pressure in the boiler, which again depends on the steam consumption, is often done mechanically. An innovation (D.R.P. No. 287,194) provides that besides the constant effect on the damper of the steam pressure, it is automatically closed when the fire door is opened, and opened fully again when the fire door is closed.

A suction smoke exhauster and cleaning device is patented (D. R.P. No. 306,668), consisting of rotating water and guide wheels and means by which the dust and gases are intimately mixed with the water.

A new apparatus for delivering and distributing the fuel on the grate is patented (D.R.P. No. 308,037), which works with a shuttle movement.

An improvement (D.R.P. No. 309,727) on a previous patent (D.R.P. No. 303,646) consists of a steam-jet tube cleaner for cleaning out locomotive boiler tubes while making a journey.

Two special spraying burners for liquid fuel are mentioned. The first is (D.R.P. No. 306,788) a further improvement of the burner, and (D.R.P. No. 296,485) has a ceramic nozzle and steel needle. The second is a revolving sprayer (patent number not given). The fuel as it leaves the nozzle is thrown sideways as much as possible, and forms a conical circle which insures the correct mixture with air being obtained. The atomized fuel and air intermingle completely, whereas in other systems on the same principle the mixture is not perfect and combustion suffers accordingly.

The last patent described (D.R.P. No. 309,345) consists of an automatic control, by means of which the liquid fuel is shut off if the boiler-feedwater supply fails. (*Technical Supplement to the Review of the Foreign Press*, vol. 3, no. 6, March 18, 1919, p. 182-183, no. 4478. *d*)

SPECIAL MACHINERY

Continuous Centrifugal Separation Machines. Description of the continuous centrifugal separator built by a South African firm. As shown in Fig. 13, it consists essentially of two vertical cylinders or bottomless buckets *A* revolving rapidly in a frame *B* around an upright spindle *C*. Each of the two buckets has an independent revolution on its own axis. The pulp or slime to be separated is fed into each bucket by a chute *D* against the outer wall, i.e., at the point farthest from the central spindle. The centrifugal force packs the solid matter of the pulp against the wall of the bucket, the fluid flowing over the upper rim and carrying the colloids with it. If desired, by lengthening the time of separation, both crystalline and colloidal solid matter may be packed against the side of the bucket and only a clear liquid is

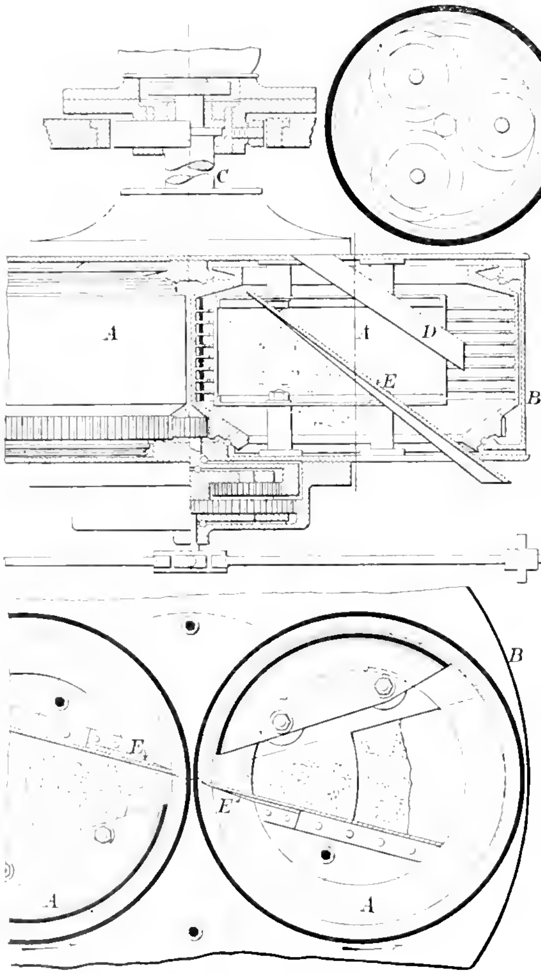

Fig. 13. Continuous Centrifugal Separator

then discharged over the rim. The slow revolution of the bucket continually carries away the clean and dry solids packed against the wall from the point of feed, so that a fresh face is constantly exposed to the feed flow. The packed solids are carried around in the bucket until they arrive at the inner wall or at the point next to the central spindle. Here the centrifugal force, which at first packed them against the wall, exercises a reverse effect and disengages them with the aid of a plow *E*, so that they fall down and out into a proper receptacle. The revolving bar of the machine is 3 ft. 6 in. in diameter. The machine is capable of treating over 25 tons of dried material per 24 hours.

It is claimed that this machine is capable of handling silver, copper, and even tin slime, of which the latter has been hitherto particularly difficult to handle. Another type of the same machine is also described in the original article. (*Engineering*, vol. 107, no. 2776, March 14, 1919, pp. 354-355, 7 figs., *d*)

New Puddling Mill at Dover, N. J. In the last few decades there has been practically no expansion of the merchant-bar-iron industry, the existing plants working mainly along the old lines. In view of this situation the erection of a new and modern puddling mill by the Ulster Iron Works, of Dover, N. J., may be considered as a very important development in the progress of this industry in the East.

The new plant now contains eleven complete double puddling furnaces and space is provided for a second similar group. The furnaces themselves are of the standard type. They burn bituminous coal under forced draft and each furnace is surmounted by a waste-heat boiler for generating steam required in the operation of the rolls and pumps and generation of electric current.

For rolling the puddle balls into blooms there is a squeezer of the rotary type. In addition an alligator squeezer was installed for upsetting the blooms. The puddle bars are rolled in an 18-in. three-high puddle train. Further refining and rolling of the puddle bars is to be carried out at the company's old plant where the equipment includes a 20-in. bar mill and other apparatus. A modern feature in the new plant is the extensive use of labor-saving devices. For delivering the puddling balls to the squeezer the old-fashioned handcar has been replaced by a monorail system. Blooms are transferred automatically from the squeezer to the puddle train. The raw materials are handled by two overhead conveyors which also remove ashes and cinder from the building.

On the other hand, however, side by side with these most modern devices is to be found the actual process of making the iron, which is the same as that discovered in 1830 by Joseph Hall, the only difference being the use of the double puddling furnace instead of the old pig-boiling process. (*The Iron Trade Review*, vol. 64, no. 11, March 13, 1919, pp. 699-701 7 figs., *d*)

RAILROAD ENGINEERING (See Also Engineering Materials)

Large Consolidation-Type Locomotives for the Philadelphia and Reading Railroad. These locomotives are notable for their weight and hauling capacity and also because they are the only engines built to a railroad company's design to be included in the 1430 locomotives ordered last year by the Railroad Administration.

They are designed for heavy drag service and are in many respects similar to the Mikado-type locomotives which preceded them. On the other hand, there are a great many differences.

TABLE 4 COMPARISON OF P. & R. CONSOLIDATION AND MIKADO TYPE LOCOMOTIVES

Type	2–8–0	2–8–2
Tractive effort, lb.	61,260	57,320
Total weight, lb.	281,100	329,300
Weight on drivers, lb.	250,800	246,600
Diameter of drivers, in.	55½	61½
Cylinders, diameter and stroke, in.	25 x 32	24 x 32
Steam pressure, lb. per sq. in.	200	225
Heating surface, total evaporation, sq. ft.	2655	4224
Heating surface, equivalent, sq. ft.	3518	5264
Grate area, sq. ft.	94.9	108
Tractive effort × diam. drivers ÷ equivalent heating surface	966.5	699 7
Firebox heating surface ÷ equiv. heating surface, per cent	8.4	6.2
Grate area ÷ vol. cylinders	5.2	6.4

As shown in Table 4, the new locomotives have smaller driving wheels and lower boiler pressure than the Mikado, but the cylinders are 1 in. larger in diameter and the starting tractive effort almost 4000 lb. greater than in the Mikado. There is also a

considerable sacrifice in heating surface, as there are eight less superheater units and 20 less tubes than in the Mikado type, and the tubes themselves are 4 ft. 2 in. shorter. For heavy drag service, however, high tractive effort at slow speeds is more important than high sustained horsepower capacity.

Because of the relatively smaller diameter of the wheels a firebox of sufficient depth can be placed above the rear drivers without raising the boiler center to an excessive height, in this instance 9 ft. $7\frac{1}{2}$ in. above the rails.

The smokebox is comparatively short, and is equipped with the Economy front and arrangement, patented by I. A. Seiders, superintendent of motive power and rolling equipment of the railroad. A special feature of this arrangement is a breaker plate, which consists of a slotted plate fitted with deflecting vanes. This plate is placed under the superheater damper and in front of the tubes, and is very effective in breaking up the large sparks before they strike the netting. The netting frames are most substantial in construction, and the device has proved effective in preventing the setting of fires due to escaping sparks. (*Railway Age*, vol. 66, no. 12, March 21, 1919, pp. 760-762, 2 gfs., *d*)

GONDOLA CAR OF REINFORCED-CONCRETE CONSTRUCTION. Description of a reinforced-concrete car of the gondola type, comprising steel center sills with concrete floor, sides and ends. (See Fig. 14).

The steel skeleton body is mounted upon the standard center sills and bolsters of the United States Railroad Administration 40-ft., 50-ton gondola car. Concrete walls and floors are contained within the skeleton steel frame, and together with the reinforcement in the floor, are connected to the underframe in such a manner that the buffing and pulling stresses are distributed throughout the car body. The unit stresses in the steel were limited to 16,000 lb. per sq. in. and in the concrete to 1000 lb. per sq. in.

FIG. 14 REINFORCED-CONCRETE GONDOLA CAR

The car has an overall length of 41 ft. $6\frac{1}{2}$ in. and overall width of 10 ft. $2\frac{7}{8}$ in., with sides 4 ft. $10\frac{1}{2}$ in. high. The concrete work on this car represents the first commercial application of a light-weight aggregate known as Haydite. It is stated that this material was developed by Stephen J. Hayde of Kansas City, Mo., but no information as to the process is given. *Railway Age*, vol. 66, no. 12, March 21, 1919, pp. 776-777, 3 figs., *d*)

A NEW METHOD OF PRESERVING RAILWAY TIES. The method described by the author consists first in drying the ties and sealing them against moisture.

Essentially, an attempt was made to use the same process that nature does but faster than nature unassisted can accomplish the work. An effort was made to dissolve, neutralize or wash out the sap or other liquids or semi-liquids which obstruct and close the pores, and to do this warm vapor, or, in other words, warm saturated air with moisture is circulated among the ties. This opens and cleans the pores in the wood. Further, the liquid components of the saps and resins filling the vesicles expand with the heat and force their way out to be diluted and carried away by the warm vapor. After some hours of this treatment the amount of moisture is reduced by very slow degrees until at the end it is practically dry and the timber is removed with not more than 5 per cent of moisture left in it. Care is taken not to let the temperature of the kiln get above 160 deg. fahr. so that no injury may be done to the fiber of the wood.

The author believes that so long as the timber so treated is kept dry, it is indestructible except by fire. The elements of decay being entirely removed from the inside, all that is necessary is to keep them from entering from the outside and to do this some waterproofing coating, preferably a cheap one, is desirable.

In the experiments conducted a heavy oil tar was found which is an almost worthless by-product of refineries. The ties were merely dipped in a hot bath of this material for a few minutes and on coming out were sanded by a sand blast to absorb any superfluous stickiness and make them easier to handle.

One of the prospects opened up by this new process is the possibility of using for ties, timbers which cannot be used now. For instance, the northern birch is a strong, reliable and hard wood which cannot be used for ties or bridge timbers on account of its superabundant sap and consequent tendency to rot rapidly. Poplar and balsam belong to the same category. All of these and other similar timbers, it is claimed, can be employed when treated by the process described here. (*Railway Age*, vol. 66, no. 13, March 28, 1919, pp. 849-850, *eA*)

VARIA

ZIRCONIUM AND OTHER STEELS. In an interesting editorial *The Iron Age* calls attention to the fact that steel containing zirconium promises to play an important role in the future metallurgy of the steel industry.

Information has been published recently in France regarding some of the properties of zirconium steel. From this it appears that such steel not only possesses a very high tensile strength and an elastic ratio of over 85 per cent, but also in toughness surpasses any other steel hitherto made.

The chief difficulty in this connection had evidently been, and still is, the production of uniform ferrozirconium, one containing definite amounts of the metal and correspondingly regular amounts of other ingredients or the absence of them, and it is evident that until such ferrozirconium is secured definite scientific progress will be impossible.

Considerable concern is reported as to the future supply of vanadium. In view of the rapid exhaustion of present resources it may be necessary to find a substitute for this important alloying metal. It is hoped that this may not be the case, for the value of vanadium has been eminently demonstrated. However, should the need come, it may develop that zirconium or titanium can take the place of vanadium to a greater or less degree. Already the interest in titanium as an alloy in steel has been active and unusual results are reported from its value as an alloy in steels and not simply as a cleanser.

The zirconium steel which has given the best results in France is stated to have the following composition and physical properties:

Carbon	0.42 per cent
Manganese	1.00 per cent
Silicon	1.50 per cent
Nickel	3.00 per cent
Zirconium	0.34 per cent

Tensile strength....198 kg. per sq. mm. (281,560 lb. per sq. in.)

Elastic limit....169 kg. per sq. mm. (240,320 lb. per sq. in.)

Brinell hardness....470 (weight of 10-kg. ball making an impression 2.8 mm.)

(*The Iron Age*, April 17, 1919, p. 1030, *g*)

Yearly subscription $3.00, single copies 35 cents. Postage to Canada, 50 cents additional; to foreign countries **$1.00 additional.**
Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

Members of the Society who participated in the enjoyable trip to England in 1910, and who remember with the greatest pleasure the hospitality extended by Capt. A. E. S. Hambelton of the SS. *Celtic* who conducted the party across, will regret to learn of the Captain's serious injury as a result of having been struck by an auto truck. Captain Hambelton is in Bellevue hospital where he has been confined for ten weeks, but is making a good recovery and hopes to be about again soon, although as yet he is still incapacitated.

Reunion of "Eighty-niners"

American Society of Civil Engineers
American Institute of Mining Engineers
American Society of Mechanical Engineers
American Institute of Electrical Engineers

Thirty years ago a party of American engineers, with members of their families, belonging to the four national engineering societies, sailed for Europe visiting England and the Paris Exposition of 1889, and being the recipients of many high courtesies, official, professional and individual.

Plans have been made for a Reunion Dinner, to be held in New York City, about May 26, at which it is hoped that all the survivors, ladies as well as men, of that memorable trip may meet again.

While the records of the various societies furnish an approximately complete list of the party, it is possible that some have been overlooked, or that addresses require correction.

It is therefore urgently requested that any one who was of that party communicate immediately with the Secretary of the Committee, Mr. Jesse M. Smith, Engineers' Club, 32 West 40th Street, New York, N. Y. This information is desired from every member of the party, whether attendance at the function is possible or not; those who cannot come will be heartily remembered when their letters are read.

It is hoped that the response to this request will be immediate and complete; the time is brief and the information required important.

Announcement of the precise date and place, and full details, will be sent to every individual who can be reached. Send in your name now and resolve to come to meet your traveling companions of thirty years ago.

Henry R. Towne, *Chairman.*
Jesse M. Smith, *Secretary.*

April 15, 1919.

Federal Board of Vocational Training

The great difficulty encountered by the Government in re-educating disabled soldiers and sailors is to acquaint them with the opportunities available. The ignorance of the average man regarding the Government and what it stands ready to do for him is most amazing. There are many men now in civil life, badly handicapped by injuries received in the war, but nevertheless endeavoring to work. In the hope that the condition of these men may be somewhat alleviated the Federal Board for Vocational Training has issued a notice giving full particulars regarding vocational training which is supplied free of cost, and with compensation during training based on the amount to which a man would be entitled under the War Risk Insurance Act. Further information is given regarding the supplying of artificial limbs or other appliances, and, if needed, medical treatment.

All disabled soldiers and sailors who desire aid should address their communications either to the Federal Board of Vocational Training at Washington, D. C., or to the District Offices located in Boston, New York, Philadelphia, Washington, Atlanta, New Orleans, Cincinnati, Chicago, St. Louis, Minneapolis, Denver, San Francisco, Seattle and Dallas.

Sir Robert Hadfield Prize

Sir Robert Hadfield, D.Sc., F.R.S., has placed in the hands of the British Institution of Mechanical Engineers the sum of £200, the income from which is to be awarded at the discretion of the Council of the Institution as a prize or prizes for the description of a new and accurate method of determining the hardness of metals, especially of a high degree of hardness. Ordinary tests are described in the Report of the Hardness Tests Research Committee (Proceedings of the Institution of Mechanical Engineers, 1916, pp. 677 to 778) and should be consulted by all competitors. Any tests offered should be a description of a method suitable for metallurgical work, and which can be used to determine accurately the degree of hardness in cases where present methods fail. The offer will be withdrawn January, 1922, and communications prior to that time should be addressed to the Secretary, The Institution of Mechanical Engineers, 11 Great George St., Westminster, London, S. W. 1.

Screw Thread Commission

The Screw Thread Commission, which has been extended until March 21, 1920, by an act of Congress passed February 28, has recently circulated a questionnaire relative to Acme threads. Information is desired regarding the sizes and extent of use of Acme threads in order that a tentative standard may be prepared. The standard is to include a series of pitches and diameters, and manufacturers and others interested can be of great service in this connection by answering promptly the questions below.

Replies should be forwarded to the Gage Section, Bureau of Standards, Washington, D. C., giving name, position, name of firm or organization, nature of product manufactured, street address and city.

1 To what extent do you produce or use Acme screw threads in your manufactured product? Give details as to the nature of your requirements for Acme threads.

2 Have you adopted, or are you using, any standards with reference to specified pitches corresponding to fixed diameters? If so, state sizes and pitches.

3 If you have no established standard, what sizes (diameters and pitches) would suit your regular needs? This information can be transmitted by detailed blueprints.

4 To what extent would a standard series of Acme threads benefit your manufacturing conditions?

5 To what accuracy is it necessary to produce Acme threads meeting your requirements? If you are working to definite tolerances on pitch diameter, lead, and angle, it is requested that details of this information be furnished.

SPRING MEETING OF THE A. S. M. E.

As previously announced, the Spring Meeting this year to be held at Detroit, June 16 to 19, inclusive, begins on Monday of the week of the convention instead of on Tuesday, the usual day for the opening session. Both the Committee on Meetings and Program, which has general charge of the convention and arranges the professional program, and the Detroit Local Committee, have plans well matured which are of such a character as to awaken the greatest interest and enthusiasm on the part of the membership. The attendance is sure to be large and every member who can do so is urged to take advantage of this unusual opportunity to meet so large a number of the engineers of the country and to enjoy and profit by the attractive features which the Detroit Committee are arranging for their guests.

Hotel Statler, Headquarters of the A. S. M. E. Spring Meeting, June 16-19

Rooms Should Be Reserved at Once

The headquarters for the meeting will be at the Hotel Statler where reservations should be made as early as possible. For the convenience of guests the following rates are given by the Hotel Committee, both for the Statler and the other leading hotels of the city:

Hotel Statler: \$2.00 to \$2.50 (limited in number)
3.00 (a few available)
3.50 (plenty available)
5.50 and up, rooms with double beds (plenty available)

Hotel Pontchartrain: \$2.00 up (rooms getting scarce for June)
Hotel Tuller: \$1.75 up (rooms scarce for June)

General Arrangements

The General Committee at Detroit having in charge the local arrangements is headed by H. H. Esselstyn, Commissioner of Public Works, with whom are coöperating Ralph Collamore, Vice-Chairman, Fred H. Mason, Secretary and Treasurer, and other members comprising this Committee, besides sub-committees on Reception, Hotels, Transportation, Finance, Entertainment, Printing, etc., and the Women's Committee, of which Mrs. F. G. Ray is Chairman.

A feature of the meeting will be a session in charge of the regular Detroit Local Committee, of which Mr. E. C. Fisher is Chairman. Papers will also be contributed by the Local Sections at Chicago, Cincinnati, Cleveland, Atlanta and possibly by others.

The Research Committee of the Society which is now so active in collecting and publishing in Mechanical Engineering research data regarding the work of the various laboratories of the country, will have charge of one session and the Gas Power Committee of another, taking up the subject of oil engines. A general session of interest to every member regardless of his specialty of engineering will be devoted to Industrial Relations, at which there will be addresses by prominent men in the industrial field discussing the relations existing between employers and employees under the present conditions and what must be done in order to preserve industrial peace.

As announced more fully in Section 2 of this number, plans are being made for a very attractive excursion, partly by boat and partly by rail, for those going to Detroit from the East. A blank is provided with this announcement which all who contemplate going on this excursion are requested to fill in.

Among the many social functions contemplated by the Detroit Committee are two of unusual interest in which all will wish to participate. One of these is an afternoon and evening on the Lake, which occurs on Wednesday, June 18, with a trip across Lake St. Clair and the St. Clair Flats—the "Venice of America" —on the boat *Britannia*. There will be music and dancing, and dinner will be served.

On Tuesday evening a social evening is planned, preceded by a lecture of popular interest, after which there will be music, dancing and refreshments. The ladies will be invited to enjoy a visit to Belle Isle, Detroit's beautiful playground, to participate in automobile trips, a visit to the Country Club, etc.

A Glimpse of Detroit's Fine Office Buildings Near Headquarters at Hotel Statler

Outline of Program.

Monday, June 16: Opening of headquarters and registration. Business meeting in the afternoon, followed by a general meeting at which the Committee on Aims and Organization

will make a preliminary report. This will cover one of the most important matters which has yet come before the Society, in that it involves a discussion of the aims and purposes of the Society and its work. In the evening there will be an informal reception at the hotel.

Tuesday, June 17: Research Session in the morning and Industrial Relations Session in the afternoon. Social evening with lecture, music and dancing. Should it be necessary, the professional sessions on this day will be paralleled by others at which papers offered by the Local Sections or by individual members will be presented.

Wednesday, June 18: In the morning, a session in charge of the Detroit Local Committee and Miscellaneous Session. Afternoon and evening, boat trip and dinner on the Lake.

Thursday, June 19: In the morning, Gas Power Session and Miscellaneous Session. Excursions in the afternoon.

For particulars regarding the proposed excursion to Detroit from the East, by boat and rail, with return blank for those to fill out who expect to go on this excursion, see inside front cover of Section Two of this number. Special cars will leave Eastern cities on Friday evening, June 13. Entertainment and short excursions will be provided both in Buffalo and Cleveland for those arriving in those cities on Saturday, and on Sunday both contingents will meet and continue by boat to Detroit.

Manufacture of Precision Gage Blocks at the Bureau of Standards

REFERENCE was made in the March number of MECHANICAL ENGINEERING (p. 289) to the sets of precision gages completed at the Bureau of Standards with an accuracy of a few millionths of an inch. H. L. Van Keuren, Chief of Gage Section of the Bureau, has published in *American Machinist* of April 3, an account of the process for manufacturing these gages, which are the invention of Maj. William E. Hoke.

One of the first problems was the selection of a material which would combine a suitable coefficient of expansion with permanency, wearing qualities, resistance to corrosion, susceptibility to high polish, ease of machining and uniformity of structure. Many possibilities such as agate, fused quartz, stellite, invar, pack-hardened machine steel and tool steel were given very careful consideration; but as in practically every case these precision gages are used for verifying other gages which are of steel or pieces and parts made of steel, the convenience of avoiding the corrections due to different coefficients of expansion when the measurements are not performed at the standard temperature determined on the adoption of a steel having a carbon content of 1.00 to 1.25 per cent (the regular tool-steel carbon content) and from 1.00 to 1.50 per cent of chromium to prevent corrosion.

The various operations required for finishing the gages are as follows:

Number of Operation	Description of Operation	Number of Operation	Description of Operation
1	Stock	9	Finish grind radius on edges
2	Turn, drill, ream, countersink one side, cut off	10	Rough lap
3	Rough grind the cut-off side	11	Inspect
4	Countersink the cut-off side	12	Lap countersink, both sides
5	Mark size	13	Finish outside diameter
6	Heat treat	14	Finish lap faces
7	Rough grind faces	15	Final inspection and measurement
8	Season	16	Assemble in sets
		17	Pack and ship

In the hardening operation, No. 6, the gages are preheated slowly to a temperature of from 800 to 1000 deg. fahr. They are then placed in a lead pot and heated to from 1550 to 1569 deg. fahr. It is said that quenching from this temperature into water through oil results in gages which have a hardness ranging from 90 to 95 scleroscope scale, and the number of cracked gages is reduced to a minimum.

In operation No. 8 the gages are given a seasoning treatment which consists of immersing them alternately in boiling and ice water about 30 times and holding them there just long enough to attain the temperature of the liquid.

The finish-lapping of the gages, operation No. 14, is done on the Hoke lapping machine. In this device the work is done on a lapping fixture driven by a vertical drilling machine and consisting of three plates; the lower and upper plates are lapping plates and are secured against rotation; the intermediate plate, which is the gage-block carrier, rotates and oscillates at the same time. The thickness of the blocks is equalized by transposing them diametrically and at 90 deg. at various times during the process of lapping. Another machine for lapping precision blocks is described and illustrated in *American Machinist,* March 27, p. 613.

The final inspection listed under operation No. 15 is made in the optical laboratory with the use of the light-wave interference method. The apparatus employed includes only two optical glass flats and a source of light. The process consists of wringing two glass plates on each end of the gage and determining with suitable apparatus the number of light waves between the gage planes. Inasmuch as the exact number of light waves in a length represented by the international standard meter has been determined to within an accuracy of about one part in 15 million, the length of a light wave is very definitely known and is constant. Therefore the determination of a number of light waves between the two glass planes on each end of the gage is equivalent to determining the exact length to a high degree of accuracy. The use of a source of light of one color, such as helium or a mercury-vapor lamp is not absolutely necessary, but in this case the interference bands take the form of more definite light and dark spaces, and thus the inspection is facilitated; with daylight the interference bands are made up of several colors merging into one another. The entire process of comparing gages by the light-interference method is extremely simple, and the cost of the measurement and inspection, including the determination of the standard for each size gage, is in the neighborhood of seven cents per gage.

University Teaches Naval Architecture

The University of Michigan announces the introduction of an intensive training course in Naval Architecture into its curriculum. The course begins January 6, 1919, and will run for eleven weeks.

The announcement states that applicants to be enrolled should be graduates of civil, mechanical, electrical, mining or architectural engineering courses, or should have the equivalent of such training. Men who have completed their junior year in college in any of those engineering courses will be given consideration as applicants. The tuition is $32.25 for the course, payable to the University, each student to pay his own expenses. Prof. E. M. Bragg is at the head of the course, which is designated the Department of Naval Architecture.

The Education and Training Section of the Emergency Fleet Corporation is coöperating with the University to make the course a success. While it does not guarantee the employment of men by shipbuilding companies, and will not employ such men itself on completion of the work, the Section will assist in obtaining work for men who finish the course successfully and who may be recommended by the Department. (*Emergency Fleet News,* Dec. 5, 1918, p. 5)

Interesting Figures on Munitions Production

An advance summary of certain features of the forthcoming report of the Secretary of War as Director of Munitions, was published in the New York *Times,* April 6, 1919. This summary was prepared by Col. James L. Walsh and contained the following data of engineering interest.

Before the United States entered the war a total of 50 machine

guns was the standard equipment of an infantry division. When the armistice was signed the total machine-gun equipment of a division consisted of 768 light automatic and 262 heavy machine guns—an increase of 2060 per cent.

Of shoulder rifles there were produced in the 19 months of our participation in the war over 2,500,000—France produced only 1,400,000 and England 1,970,000. Of small-arms ammunition for pistols, rifles and machine guns 2,879,148,000 rounds were produced between April 6, 1917, and November 11, 1918, a total of one complete round every 20 seconds for 1918 years. Of machine guns and automatic rifles, America produced a total (181,662) slightly greater than that of England (181,404), and slightly less than that of France (229,238); but a fairer basis of comparison—the average monthly rate of production—indicates that America was producing 27,270 per month, more than twice as many automatic rifles and machine guns per month as France (12,122), and nearly three times as many per month as England (10,947).

As to artillery ammunition, a typical instance is the 75-mm. project. Of this caliber four and a quarter million of high-explosive shells, more than a half million of gas shells and over seven and a quarter million of shrapnel had been produced complete when the armistice was signed. From January 18, 1918, when the first complete American division entered the line, until firing ceased on November 11, 1918, a total of six and a quarter million rounds of 75-mm. ammunition were e pended by American artillerymen.

Efficiency the Keynote in Shipbuilding

Holden A. Evans, president of the Baltimore Dry Docks and Ship Building Company, spoke recently on the question, What is to be done to make possible the continuance of shipbuilding in this country? His answer is that only through the removal of the various inefficiencies that now exist in the industry and by the education and training of workmen can this be done.

Before the war cargo ships were built in Great Britain at from \$30 to \$40 per deadweight ton. At the same time, some cargo ships of similar type were built in this country at from \$60 to \$70 per deadweight ton. Today contracts are being placed in Great Britain at \$100 to \$120 per deadweight ton. In this country, under present conditions, it will cost the shipbuilder from \$170 to \$180 a ton to build the same ship.

Wage schedules are today double what they were before the war and steel plates which could then be bought at \$1.10 have risen as high as \$3.25. The high cost of construction is obviously due in part to the increase in labor and materials; but principally, Mr. Evans contends, to *inefficiency*, which he classes under the following heads:

The inefficiency of a large number of unskilled men taken in the yards, due to the enormous plant expansion.

Inefficiency due to rush war methods. Speed of construction has been the only thought, which brought about extravagant methods. Old trained men are not as efficient today as they were before the war. It will take some time to bring them back to normal efficient methods.

The inefficiency due to the rapid increase in wages. The men do not work as steadily as before the war. There is much more lost time.

He adds: "The American people are thoroughly convinced of the absolute necessity of our own merchant marine, and we are going to have it. But if we are to maintain a great American-built, American-operated merchant marine, the American people must in some way or another pay for the excess cost while we are learning to build and learning to operate. In no other way will we ever get it."

NATIONAL RESEARCH COUNCIL

THE National Research Council of the National Academy of Sciences, which has been one of the potent factors in the development of scientific and research problems during the war, has now been organized on a permanent basis in order to promote research in the mathematical, physical and biological sciences and in the application of these sciences to engineering, agriculture, medicine and other useful arts.

Throughout the period of our participation in the war the National Research Council conducted a very large and successful work, largely through the foresight and active direction of its distinguished chairman, Dr. George E. Hale, director of Mt. Wilson Observatory. Doctor Hale had previously been in Europe investigating research matters and brought to the Council an intimate knowledge of accomplishments in other countries and of the requirements which the Allies of the United States had found necessary to meet in the research field. It is hoped that the Council may long have the continued service of Doctor Hale in his capacity as chairman whereby he has contributed so much of his enthusiasm and scientific knowledge to the advancement of science and the arts in America.

In this connection, it is interesting to note that the National Academy was organized at the request of President Lincoln to meet the scientific needs of the country during the Civil War; and likewise the Research Council came into existence by an executive order of President Wilson to extend the work of the Academy into a broader field of research during the recent war.

The permanent organization of the National Research Council replaces the temporary organization under which it has heretofore operated, and its membership is to be chosen with a view to forming an effective federation of the principal research agencies in the United States concerned with the field of science and technology. It is to consist of

(1) Representatives of national, scientific and technical societies.

(2) Representatives of the Government, as members and provided in the executive order.

(3) Representatives of other research organizations and other persons whose aid may advance the objects of the Council.

Organization of National Research Council

The Council is to be organized in two divisions,—one of General Relations dealing with foreign and states relations, educational relations, industrial relations, etc.; and the other of Science and Technology. The latter will include divisions of physical sciences, engineering, chemistry and chemical technology, geology and geography, medical sciences, biology and agriculture, and anthropology and psychology.

To secure the effective federation of the principal research agencies in the United States, a majority of the members of each of the divisions of science and technology are to consist of representatives of scientific and technical societies. The other members are to be nominated by the executive committee of the division, approved by the executive board of the Council, and appointed by the president of the National Academy.

The affairs of the Council are to be administered by an executive board of which the officers of the Council, the president and the home secretary of the National Academy of Sciences, the president of the American Association for the Advancement of Science, the chairman and vice-chairman of the Divisions of Science and Technology, and the chairman of the Divisions of General Relations shall be ex-officio members.

National Research Fellowships

The very large way in which the Research Council is functioning is indicated by the recent support accorded to it by the Rockefeller Foundation through an appropriation of \$500,000 to be expended within a period of five years for promoting fundamental research in physics and chemistry, primarily in educational institutions of the United States. The primary feature of the plan is the initiation and maintenance of a system of National Research fellowships to be awarded by the National Research Council to persons who have demonstrated a high order of ability in research for the purpose of enabling them to conduct investigations at educational institutions which make adequate provision for effective prosecution of research in physics or chemistry. It is expected that 15 to 20 research fellow-

ships will be available during the coming year and that the number will be increased in subsequent years. The Research Fellows will be permitted to conduct their investigations at institutions that will coöperate in meeting their need and that are amply supplied with equipment, and above all, that are conducted in the stimulating atmosphere to be found only in institutions that have brought together groups of men devoted to the advancement of science through the pursuit of research.

Applications for these fellowships should be made on the form provided for the purpose and should be sent to the secretary of the Research Fellowship Board, National Research Council, 1023 16th Street, Washington, D. C.

Representatives Abroad

Two distinguished representatives of the National Research Council have recently left for Europe on important commissions. Dr. Charles S. Howe, president of Case School of Applied Science, sailed for France on April 19, where he will assume the duties of scientific attaché to the United States Embassy in Paris. This appointment is regarded as a notable development in the American diplomatic service produced by the war and the appointment will be watched with interest, as it is expected the industries of the country will be materially assisted by authentic information on the scientific discoveries which may be made in Europe. Dr. Comfort A. Adams sailed for England on April 14, and later he will go to France to attend the conference of the International Electro-Technical Commission to be held in Paris.

ENGINEERING DELEGATES REPORT TO FRENCH CONGRESS

The American delegation of Engineers who recently went abroad to investigate reconstruction problems, rendered a preliminary report to the Congres General du Genie Civil previous to returning to this country. A summary of this report was recently presented to the Council of The American Society of Mechanical Engineers by Mr. Charles T. Main, Past-President of the Society and its representative on the delegation. The following abstract brings out some of the most interesting features of the report.

There is but one national engineering society in France, the Société des Ingénieurs Civils, which includes engineers of all branches of the profession. It was not unnatural, therefore, that when the invitation was sent to the American engineers that it should have been addressed to the American Society of Civil Engineers. Nearly all of the problems submitted to the American Delegation were problems in civil engineering, and only incidentally those which might be classed under the headings of mechanical, electrical or mining engineering.

At the time of their appointment the delegates were of the impression that the problems which were to be discussed with the French engineers were those concerning the reconstruction of devastated areas. It soon developed, however, that this was not the case, and that the problems to be considered were of a much broader scope, and those which would profoundly affect the future policy of the development of the Republic. While these problems were of broad interest and great importance, they were nevertheless not so definite and of such immediate interest as would have been those dealing directly with the subject of reconstruction.

Ports and Inland Waterways

Among the recommendations made to the French engineers were a number relating to the development of ports and inland waterways. The desirability of concentrating on the improvement of a few principal ports rather than scattering efforts over many large and smaller ones, was pointed out, and the use of modern freight-handling apparatus and close connection between railroad tracks and wharves to reduce the time of vessels spent in port, strongly urged. A more limited use of enclosed basins with locks was also suggested, and the advantages of wharves with suitable loading and unloading apparatus, and a sufficient number of dry docks and facilities for repairs, were enumerated.

The Delegation also recommended that financial accounts and statistics relating to each port should be kept separate from those of other ports, so that the relative efficiency should be determined.

Water Power

The Delegation did not feel inclined to discuss the laws relating to water power, as they were too complicated, but it did recommend that no project should be undertaken unless it could be demonstrated to be economically justified. The Government, it suggested, should encourage these enterprises and render financial aid, temporarily or permanently, in view of collateral advantages.

The necessity of standardizing the characteristics of their electric systems and the possibility of making one great connected system for the entire country was discussed, and recommendations of 50 cycles for local distribution and 25 cycles for long distance were made for careful consideration.

The Delegation also recommended that effective measures be taken to facilitate the extension of existing installations and construction of new ones where such extensions or new construction are justified. France has within her borders, in three rather widely separated regions, water-power possibilities which are probably sufficient, if developed and utilized, to obviate the necessity now existing of importing coal for power purposes. The importance and desirability of a unified system is emphasized by the study of the seasonal characteristics of the flow of the streams in the different regions. The low-water flows in these several regions do not occur simultaneously and thus combined operation will make it possible to utilize a greater amount of continuous power than could be utilized if the various groups of plants were operated independently. No insurmountable technical difficulties stand in the way of operation of such a unified system, and while the data for an exact study of the cost and results of interconnecting the several regions were not at hand, a general consideration of the situation led to the opinion that it would be amply justified. It was recommended that steam plants be connected to the general distributing system and operated in such a way as to supplement the varying amount of power which can be derived from hydraulic sources. The concentration of electric power production by steam in a small number of large, modern plants will result in a great economy of coal as compared to the amount required to produce equivalent power in a large number of small steam plants; and at high potential, such as is now in successful use in America, electric energy can be transmitted for much less than the cost of transporting the coal required to produce the same amount of energy. The use of auxiliary steam power developed in large plants properly interconnected with hydroelectric plants can be utilized advantageously in supplementary power from the latter at certain seasons of the year.

Navigable Waterways

With a few special exceptions, the experience with works of inland navigation in the United States has been disastrous. In France, however, the conditions are more favorable. The Government there has assumed the payment of interest on works of internal navigation, and also expenses of maintenance.

The four purposes of control of a river are the development of power, irrigation and domestic water supply, improvement of navigation, and regulation of floods, and these should always be considered together. No project should be undertaken which will not be economically justified when all uses are considered and all charges included.

Roads

In the past the French used broken stone for their highways but such construction is now unsuited to the traffic. The Delegation accordingly advised the use of cement concrete, bituminous and brick coatings, the preference depending on climate, trav

and cost. Brick coatings can be used in exceptional cases only: cement roads only where materials are at hand at a low price.

On account of the enormous destruction of roads during the war, considerable reconstruction is necessary, but it has been found that in most cases the existing foundations can be used. Under the present laws bonds cannot be issued for this work, but it is necessary to have appropriations made by the various territorial departments or by the communes. Some arrangements, it was suggested, might be made with private enterprises for constructing and maintaining the roads.

Agriculture

The rehabilitation and expansion of agriculture should be based on improved financial facilities, which require modifications in the banking laws of France. To this end the delegation recommended that working capital for farmers should be obtained from the sale of long-term farm bonds. It also recommended safe and convenient procedures for establishing chattel mortgages; a comprehensive system of warehouse receipts, bills of shipment or lading, acceptances of commission houses, etc., so that records of property may be accepted as collateral; and amendments to banking laws to permit loans for a period in a year or more.

The establishment of modern slaughterhouses and cold-storage plants and refrigerator cars was also urged, although this also will require modification of laws to establish effective sanitary supervision. Persistent campaigns toward better hygienic conditions among the farmers were advocated, as well as rural welfare movements to increase the comforts of farm life.

Technical Education

Many papers dealing with technical education were presented to the Congress. The question was very complex, reaching from the lowest primary to the highest technical education. However, it was recommended that agricultural schools be established; also courses in chemistry and chemical engineering; and that the field and scope of engineering should be brought to the attention of students in the secondary schools, and schools should be provided to receive all young men who are qualified and desire to pursue technical studies.

The interchange of students, professors and instructors between France and America was held to be eminently desirable, but all agreed that France must offer greater encouragement than formerly if she instead of Germany is to be the place for post-graduate work.

Franco-American Engineering Committee

Pending the completion of its formal report, the Delegation of American Engineers has submitted to the national societies which it represents the following statement:

The French Congres Général du Génie Civil, at its meeting on January 15, 1919, adopted the following resolution:

"In order to study both the possibilities and the means of coöperation which have been considered between the engineering societies represented by the members of the American Delegation and the representatives of the French Civil Engineers, it would be highly desirable to maintain the contact which has just been established.

"For this purpose the formation of a permanent Franco-American Committee should be the first result of the studies and trip of inspection which has just taken place.

"The American Delegation and the delegates of the Génie Civil unite in expressing a resolution in favor of the immediate formation of this permanent International Committee."

The members of the American Delegation were requested by the French engineers to act as the American members of the Permanent International Committee. This, however, the delegation declined to do, explaining that it represented the four national engineering societies of America, to which societies it must report, and in whose hands any permanent action must lie.

However, to meet the desire of the French engineers for the immediate creation of an International Committee, and in view of the fact that the Delegation still has some work to do in preparing reports and information for transmission to the French Committee, the members of the Delegation consented to act temporarily as the American members of the International Committee, promising to bring the matter to the immediate attention of the societies they represent, and to secure immediate action if possible. Accordingly, the American Delegation, at a meeting held January 25, 1919, unanimously passed the following resolution:

Resolved: That the Delegation bring to the immediate attention of the national societies which they represent the facts with reference to the formation of a permanent Franco-American Engineering Committee, and urge upon the societies that they take immediate action to constitute the American representatives upon such a Committee.

ELECTRICAL MEASUREMENT OF FLUID FLOW IN PIPES

(*Continued from page 432*)

constant by varying the field of the generator supplying the power, thus approximating the actual condition of an average installation. The secondary voltage varied due to the transformer regulation, but the resistance element of the instrument is designed to compensate for such regulation, so that the indicated variations of current gave a fairly accurate measurement of the differential pressure.

Conclusion

The fact that the flow of fluids can be measured electrically has made possible many important installations where no other method could be employed. In one instance a large manufacturing concern had been contemplating for a long time the adoption of a system for measuring the amount of steam, air and water used by its various departments, but was hindered by the fact that the various lines were distributed over a wide area and in some places were carried through sub-basements, where measuring devices would be inaccessible; also much time and a large force of employees would be required to read the various instruments about the plant and to integrate the recording charts. As soon as the concern discovered that flow could be measured electrically, that the indicating instruments did not have to be located where the flow was to be measured, and that the integrating device was merely a watt-hour meter which integrated the flow independently of the other instruments, a measuring system was instituted for all its products and many wasteful uses of power were thereby eliminated and an accurate distribution of costs established throughout the factory.

The adaptability of the integrating feature to the electrical measurement of flow is of great importance since the readings from the watt-hour meter are more accurate than those taken from the recording ammeter and just as accurate as the instantaneous readings of the indicator. This feature therefore eliminates the necessity of planimetering the charts and insures accurate results for any variation of flow.

When measuring the flow of steam generated by a battery of boilers the flow indicators are placed in front of each boiler, showing the momentary performance for the guidance of the fireman. At the same time, supplementary recorders connected electrically with the indicators are placed conveniently for the supervision of the chief operator.

Recently the manufacturers of water gas adopted the use of low-pressure exhaust steam for gas generation, which created an urgent demand for a measuring device to operate intermittently, varying every few minutes from zero to maximum. After many unsatisfactory trials of mechanical devices the electrical method of flow measurement was adopted, as this made it possible to measure successfully the steam required for the manufacture of water gas and resulted in a great economy.

The main advantage, however, of the electrical method of flow measurement is the accuracy with which the differential pressure is transmitted through a mercury column, which column is not hindered in its movements by any mechanism and is therefore free to attain the true level under all conditions of flow. Furthermore, the electrical instruments used to register the flow can be checked at any time without interfering with the operation or installation of the measuring device.

ENGINEERING COUNCIL

Engineering Council[1] is an Organization of National Technical Societies of America, Created to Consider Matters of Common Concern to Engineers, as Well as Those of Public Welfare in Which the Profession is Interested

Classification and Compensation of Engineers

THE make-up of the Committee on Classification and Compensation of Engineers has been completed. It comprises a main committee and three sub-committees or sections, as follows: *Main Committee:* Arthur S. Tuttle, *Chairman;* Francis Lee Stuart, John C. Hoyt, Charles Whiting Baker, M. O. Leighton. *Railroad Section:* Francis Lee Stuart, *Chairman;* Frank H. Clark, Bion J. Arnold. *Federal Government Section:* John C. Hoyt, *Chairman;* John S. Conway, Oscar C. Merrill. *Municipal* (including City, County and State): Arthur S. Tuttle, *Chairman;* M. M. O'Shaughnessy, F. W. Cappelew. The Railroad Section has been the first to get into action, its chairman, Mr. Stuart, having appeared before the Railroad Administration's Board as reported below.

Hearing on Classification and Compensation of Railroad Engineers

AT a recent hearing by the Railroad Administration's Board on Wages and Working Conditions, arguments were presented by representatives of Engineering Council, appearing for the Societies of Civil, Mining, Mechanical and Electrical Engineers, and the Society for Testing Materials; and representatives of the American Association of Engineers.

Francis Lee Stuart opened the hearing for Engineering Council, which, he said, had been advised (1) that engineers and engineering assistants of the more important classes on the railroads have been individually considered as belonging to the Officer or Supervisory Force, and certain increases of salary have been granted them by the Railroad Administration; (2) that whereas the men in subordinate positions in the civil, mechanical, electrical and signal departments have also been granted certain increases, they have not been given a classification such as the Supervisory Force has had.

He urged that it would be for the best interest both for the social and economic welfare of the railroad professional engineers of the United States that the case of these younger engineers holding subordinate positions be further considered. Before the war the compensation of these engineers was notably inadequate and the increases which have been granted the men in the subordinate positions do not seem to them sufficient. Engineering Council, through this committee, asks that the employees of the engineering departments—civil, mechanical, electrical and signal, who were not considered in the Officer or Supervisory Force, but who will, from their technical education or training, at some later date occupy the higher positions in these departments, be given a classification and the titles of these positions standardized, and a proper remuneration be given them in order that their physical welfare and mental interest may be provided for so as to insure efficient service to the public.

Mr. C. E. Drayer appeared first for the American Association of Engineers and offered a wage schedule for subordinate engineers which had been approved by Railroad Engineers' Convention, in Chicago, on March 17, 1919.

Mr. W. C. Bolin then said it had been estimated that the education required to fill an average railway engineer's place represented a capital of $10,000. At the present scale of wages, he declared it impossible for the engineer, except under unusual circumstances, to recover his $10,000 investment in education. The apprentice in the mechanical department is better off than the boy who enters school to take an engineering course. The apprentice earns money while the other boy is spending money for education, and under the existing rate scale, the former would continue to get more money throughout his career.

The full Board was present at the hearing and manifested unusual interest in the entire proceedings. It is believed that substantial increases in salaries for the junior technical engineers on railroad work are in sight and will very probably be a reality as soon as the Board can get the additional data and information required to complete its work.

NATIONAL SERVICE COMMITTEE

Engineering Legislation in the Past Congress and in Prospect

ALL engineers should understand that legislative measures in which they are most concerned do not succeed in Congress merely by reason of merit. Such bills fail to become laws, not because of adverse votes on the merits, but because of no votes. Congress is deluged with bills. In the Sixty-fifth Congress there were over 16,000 separate and distinct measures introduced into the House, and nearly 6000 into the Senate. These, together with hundreds of joint resolutions, made up a legislative program which could not possibly be digested or appraised according to merit. The Sixty-fifth Congress does not differ from preceding Congresses in this respect, nor will it differ from future ones. Under such conditions the legislation must be the result of interested work by persistent advocates.

Engineering legislation usually fails because there are no engineers in Congress to become its champions. We fail to recall a single worthy engineering measure in the past decade that did not have voting support enough to carry it through; but this was passive support—it did not contrive an opportunity to vote. The good lawyers, farmers, journalists and business men who make up the Congress have to become engineering students when they champion an engineering measure. They have to learn fundamental principles, facts and figures, all in an unfamiliar field. These men are already too busy with subjects with which they are already familiar. Here and there men are found willing to put aside the subjects familiar to them and take up engineering matters. Of course, they merely touch the high spots, and, in common with all high-spotters, they usually "fall down hard" when they get into action.

The members of Congress are not to blame. They deserve profound thanks for their efforts and accomplishments. If any engineer doubts this, let him for the moment assume that he is a member of Congress and is suddenly called upon to familiarize himself with and champion a measure based on international law or preventive medicine. Would he perform better than the lawyer does in Congress on engineering matters? Manifestly not. Therefore let us be persuaded that so long as engineers shirk participation in legislation and remain unrepresented in Congress, just so long must their legislative measures be conducted through the parliamentary maze, not by blood relatives, but by well-meaning foster parents.

To appreciate the truth of this, one needs merely to review the proceedings of the Sixty-fifth Congress. Some of the big engineering measures arrived at the point of final vote at the eleventh hour, were caught in the jam of filibuster, and died. The Water Power Bill, for example, had been on the road for several years, and a determined push by engineer members would have undoubtedly carried it through the Sixty-fifth Congress with months to spare.

An apparent exception to these general conclusions is the case of the engineering measure for the appropriation for public highways. This bill did pass, but as a rider on the Post Office appro-

[1] Officers of Engineering Council: J. Park Channing, *Chairman;* Alfred D. Flinn, *Secretary*, Engineering Societies Building, 29 West 39th Street, New York.

Washington Office in charge of M. O. Leighton, *Secretary*, National Service Committee, McLachlen Building, 10th and G Streets.

Representatives of The American Society of Mechanical Engineers on Engineering Council: Ira N. Hollis, Charles Whiting Baker, George J. Foran, Mortimer E. Cooley, David S. Jacobus.

priation bill. It was a measure easily understood, and one in which members of Congress were personally interested, and it was practically inevitable that it would be passed.

Mineral Resources

Another bill that failed in the last Congress—that was talked to death—was the long-discussed measure for opening up the mineral resources of the public lands for development. The point to be impressed in this connection is that it is possible by strict adherence to parliamentary rules and practices for one "willful man," by means of filibustering tactics, to deny for the time being an otherwise unanimous demand. It is expected that this bill will be introduced in the next Congress, where it is hoped it will be regarded in the nature of unfinished business and thus receive early consideration and passage.

The Water Power Bill

The fate of this bill was the same as that of the Mineral Lands Bill above mentioned. For at least six years the differences of opinion which have prevented the people of this country from enjoying the economic advantages of water-power development on the navigable streams and on streams in the public lands have related to matters of minor importance from the purely development standpoint. One great bone of contention has been the matter of charge or annual payment to the Federal Government for the privilege of developing water powers. This has been of only the remotest interest to public-utility companies and to investors because the charge imposed by the Federal Government must of necessity be paid by the consumer. Nevertheless, this and other points of similar purport have brought water-power development to a virtual standstill in all situations in which the Federal Government has jurisdiction. These difficulties have at last been ironed out, and the bill will again come up in the Sixty-sixth Congress.

Good Roads Legislation

Relatively few engineers have done more than to glean from the press a general idea that the Government is embarked on a road-making policy. Yet the subject is one which demands the thought of every engineer. It is the biggest and most costly internal improvement program ever known in our history. The Federal Road Act, approved July 11, 1916, provides for an appropriation of $75,000,000 during a period of five years, allotments from which, however, are to be made only as the states add equal amounts.

Further, the Post Office appropriation bill passed by the last Congress increased the statutory limit of unit cost of highways built under its provisions from $10,000 to $20,000 per mile, and appropriated in addition to the sums above mentioned a further sum of $50,000,000 for the fiscal year ending June 30, 1919, and $75,000,000 for each of the two following fiscal years. Thus we have a total of Federal and State moneys available to June 30, 1921, of $550,000,000, to which may be added an additional $10,000,000 appropriated by Congress for roads and trails in the National Forest.

The Soldiers' Land Settlement Bill

A bill of particular interest to engineers and yet one which the Congress also failed to pass is the Soldiers' Land Settlement Plan. Under this bill returned soldiers, sailors and marines would be employed on construction work in the reclamation of swamps and arid lands, and would thereafter be given preference in the selection and settlement of those lands. A new bill has now been written for introduction at the next session which, however, instead of providing for the development of new tracts, proposes an "infiltration method" of buying improved farms in established communities. The contrast of this bill to the one recommended is of vital importance to engineers, chiefly because of the broad engineering program that the latter bill proposes as against no engineering under the infiltration method.

Those who favor the new bill argue that it will cost less than the community plan; also that a greater increase in production of food would be secured from the intensive cultivation secured thereby. On the other hand, those who favor the community plan argue that the infiltration plan is impracticable because it will not eliminate the lag of cultivated area behind our increase of population. In the ten-year period subsequent to 1900, our cultivated area increased only about one-half as fast as did the population.

It is interesting to note in this connection that the infiltration and the community plans have both been tried in Australia. The latter proved a success, whereas the former was a failure. After long and careful study, Great Britain also adopted the community plan and we have come to the conclusion that the community settlement plan is best fitted to our requirements.

War Minerals Claim

One of the most important matters now under consideration at Washington is the determination of the remuneration to producers of manganese, chrome, pyrites and tungsten, who in their efforts to meet Government requirements during the war met with heavy losses. Congress has passed a bill setting aside $8,500,000 to meet such claims, and the Secretary of the Interior has been given authority to expend this sum following proper proof of claims from the producers affected.

To assist in this important work, Secretary Lane has appointed a Commission to gather and settle these claims. The work has progressed rapidly for such matters, as a test case was heard in Washington, D. C., on April 15. The claim involved the Charles T. Pyrites and Chemical Co.

At this hearing the interested company was permitted to retain counsel, and it is therefore contemplated that other claims will be permitted to do so, although it has been pointed out by the Commission that claims without attorneys will have every opportunity to get all the facts before the Commission.

Topographic Mapping

If the topographic survey of the country does not proceed more rapidly than prescribed by Congress in the past, a generation at least will have past before the work is completed. Accordingly, Engineering Council has urged the Secretary of the Interior that he recommend to the 66th Congress the importance of increasing the appropriation for that work from $350,000 to $500,000. The importance of topographic mapping hardly needs to be urged or explained to the engineering profession.

In the execution of our national road-construction program, in water-power development, in the fields of mining and geology, in the extension of railway systems, etc., a complete topographic map of the sections involved is a fundamental necessity and becomes the greatest single aid, time saver and means of economy that can be placed in the hands of the constructors.

Proposed Pan-American Conference

A Pan-American Industrial Conference fully as pretentious as was the Pan-American Scientific Congress held in 1915 is under consideration by the Pan-American Union. It is considered practically certain that such a conference will be held. American engineering has taken such an important place in Latin America that it will occupy a prominent place on the program. This will be the first conference of the kind which will be devoted exclusively to the economic features of Pan-American relationships.

Open competitive examinations are now being advertised in the New York City Record for positions in the city employ. These include Mechanical Draftsman Grades C ($1200 to $1800 per annum) and D ($1800 to $2400) for Heating and Ventilating and Electrical Draftsmen. Those desiring to take examinations should apply on or before May 7, 1919, for the proper application blanks, addressing the Municipal Civil Service Commission, 14th story, Municipal Building, New York.

NEWS OF THE ENGINEERING SOCIETIES

Reports of Annual Meetings of Mining and Electrical Engineers and Electric Railway Association —The Aims of an Engineering Society, etc.

Newly Formed American Petroleum Institute

Government officials having to do with matters pertaining to the petroleum industry are very anxious that the newly formed American Petroleum Institute establish its headquarters in Washington. With few exceptions, the important industries of the country are represented in Washington by organizations which are prepared to give immediate information concerning any phase of their activities, and committees of Congress are coming more and more to rely on these national organizations for information.

Electric Furnace Association

On the afternoon of April 3 the recently formed Electric Furnace Association held a meeting at the Chemists' Club, New York. A tentative draft of the constitution and by-laws was adopted pending such time as is necessary to secure a representative list of members from the various industries interested in the work of the association. An aggressive campaign will be undertaken at once to secure members from manufacturers of electric furnaces, electric-furnace supplies, electric-furnace products, etc. This was the second meeting of the association, which is another instance of the present tendency of manufacturers in a given line to get together for their mutual good.

Engineering Society of Western Massachusetts

A dinner and organization meeting of the Engineering Society of Western Massachusetts was held at the Hotel Kimball, Springfield, Mass., on Wednesday evening, April 16. The following officers were elected: Charles L. Newcomb, president; C. C. Chesney, vice-president; George E. Williamson, vice-president, and Winfield E. Holmes, secretary and treasurer.

The constitution and by-laws provide for four grades of members, an entrance fee of five dollars and annual dues of the same amount.

The speakers included Prof. L. P. Breckenridge, Mr. William Spencer Murray, and Dr. George Otis Smith. Over 300 persons attended the dinner and nearly 1100 applications for membership were presented.

American Welding Society

The newly-organized American Welding Society held its first meeting in the Engineering Societies' Building, 29 West 39th Street, New York, on March 28. This is an outgrowth of the Welding Committee organized by the Emergency Fleet Corporation and the Council of National Defense to develop welding methods and coördinate the welding industries during the war. The constitution and by-laws were adopted as recommended, and it was also voted to consider all those who apply for membership before April 8 as charter members of the society. Announcement was also made of the election of Comfort A. Adams as president and the appointment of W. E. Symons as treasurer and H. C. Forbes as secretary.

The first honorary member of the society is Prof. Elihu Thomson, who was characterized by President Adams as the father of electrical engineering in this country.

The main offices of the society are located at 29 West 39th Street, New York City.

Meeting of the American Chemical Society

The American Chemical Society held its spring semi-annual meeting on April 7-11 in Buffalo, N. Y. The convention was named the "Victory Meeting" in view of the new industries which the chemists of this country built during the time of the war.

The papers and discussions presented formed a complete index to American progress in the chemical arts. A few of the topics treated in the session of Industrial and Engineering Chemistry were: Corrosion Tests on Commercial Calcium Chloride Used in Automobile Anti-Freeze Solutions, by Paul Rudnick; Non-Metallic Inclusions in Steel, by E. G. Mahin; Mineral Rubber, by Gustav Egloff; and Testing Materials for Increasing the Water Resistance of Sole Leather, by H. P. Holman and F. P. Veitch. A symposium on Library Service in Industrial Laboratories was another feature of this session. Other divisional meetings dealt with the physical and inorganic, biological, organic, and pharmaceutical applications of industrial chemistry.

New Cuban Engineering Society

There was established in Havana on the evening of February 21 the Association of Members of American National Engineering Societies in Cuba. This organization restricts its membership to persons who are members of the following American national engineering societies: The American Society of Mechanical Engineers, the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Institute of Chemical Engineers, the American Society of Agricultural Engineers, the American Society of Refrigerating Engineers, the American Institute of Mining and Metallurgical Engineers, the American Institute of Architects, the American Iron and Steel Institute, and the American Chemical Society.

There will be four regular meetings each year, one of which will be the Annual Meeting, occurring on the second Friday of December. The headquarters of the Society are located at No. 17 Empedrado, Havana.

The officers for the coming year are Luther Wagoner, president; George H. Nolan, vice-president; T. Carlile Ulbricht, secretary, and Wallace R. Lee, treasurer.

American Electrochemical Society

The best-attended meetings in the history of the American Electrochemical Society were held at the Chemists' Club, New York, April 3, 4 and 5. Only two days were devoted to technical discussions, the chief topics being the products and possibilities of the electric furnace, and the work of the electrochemist during the war. Several papers were presented relative to the first of these subjects, the most timely perhaps being one by G. K. Elliott. In his paper on improving the Quality of Gray-Iron Castings by the Electric Furnace, Mr. Elliott outlined the most recent practice of employing the electric furnace in conjunction with the cupola in a foundry. Another paper of value was one on Electric Furnaces of the Resistance Type Used in the Production of Essential War Material, by T. F. Bailey, of the Electric Furnace Co., Alliance, Ohio. Following the presentation of Mr. Bailey's paper, moving pictures were shown of several of the installations described.

The Friday session was given over to papers dealing with the work of the electrochemists during the war. The use of silicon and titanium tetrachlorides in the manufacture of compounds employed in producing smoke screens was described by O. Hutchins and G. A. Richter. Compounds of these metals sprayed into moist air are broken up into silica and hydrochloric acid, and the latter in the presence of ammonia forms dense white

fumes of particularly effective screening value. Poison gases were also developed by the electrochemists and their work along these lines was described by Col. W. H. Walker, of the Chemical Warfare Service.

Government ownership of hydroelectric power developments was also discussed and a decided difference of opinion was found to exist. The report of a committee appointed to investigate this subject was made, and while a majority of its members favored private organization and operation, a report was also submitted by the minority members favoring Government control. When, however, both reports were put to vote, the Society decided in favor of private ownership.

The Society recently held its election of officers. The new President is Lieut.-Col. W. D. Bancroft, U. S. A., of the Chemical Warfare Service and professor of chemistry at Cornell University; the vice-presidents are D. U. Dorr, W. R. Whitney, and Dr. Carl Hering. B. G. Salow was reëlected treasurer and Dr. J. W. Richards again selected as secretary.

Dinner of Utah Section of A. I. M. E.

Over two hundred engineers sat down to the dinner of the Utah Section of the American Institute of Mining and Metallurgical Engineers, held at the Hotel Utah, Salt Lake City, on Monday evening, April 7. Homer V. Winchell, president of the A. I. M. E., Prof. C. K. Leith, Adviser at the Paris Peace Conference of Bernard Baruch, Prof. J. F. Kemp, Hon. Mem. A. I. M. E., and Hon. Reed Smoot, Senator from Utah, were the speakers. Calvin Rice, Secretary of the A. S. M. E., was present, together with a number of prominent engineers of the Society and also members of the Engineering Society of Utah who had previously attended an informal dinner at the University Club in honor of Mr. Rice.

The dinner of the Mining Engineers was a great success and the spirit of coöperation and get-together of all engineers of the locality strongly emphasized. Some glimpses of the tremendous part that the mineral industry plays in the affairs of the world, together with some intimations of the gigantic task before the peace conference, now adjusting the industrial and economic machinery of all nations, some expression of the responsibility that rests upon every American to do his part of the work that lies at hand, were vividly presented.

American Railway Engineers' Association

RECENT progress in rail manufacture and testing, as well as a new method of testing rail joints, was placed on record at the annual meeting of the American Railway Engineers' Association, held at Chicago during the week of March 16th. The proposed changes in the rail specifications are slight and yet exceedingly important, for they will call for a harder rail; establish a new acceptance standard, and create an entirely new form of test to be used in place of the familiar drop-test. The required percentage of manganese in open-hearth rail of all weights is raised by 0.10 per cent, making the limits read 0.70 to 1.00 per cent. For the heavy weights of open-hearth rail, 111 lb. per yd. and over, the required amount of carbon is raised by 0.05 per cent to the figures 0.67 to 0.80 per cent. A higher ductility is also demanded, the elongation in drop test being changed from 6 to 8 per cent. Acceptance is made more difficult by requiring that all three drop or bending tests representing a given heat must pass if the heat is to be accepted.

While the drop test has also been the final physical test for rails, the experience of the Pennsylvania Railroad has so clearly demonstrated the value of a bending test that it was adopted as an alternative to the drop test. The bend test is specified to be made with a 350-ton press on a 48-in. span, and autographic records of load and deflection are to be taken; the test is to be made preferably with the rail head in tension.

Rail-Joint Tests

As the result of many elaborate tests made by the Pennsylvania Railroad to determine the strength of rail joints, the Committee on Rails submitted and there were adopted new specifications for testing rail joints. These specifications demand that the test be made in a press, the rails being supported on two supports 48 in. apart and the load applied over the joint midway of the span. Measurements of deflection and set are to be made at 3000-lb. intervals of load, and from the results of the test the efficiency of the rail joint is to be computed as the ratio of the elastic limit of the rail joint to the elastic limit of the continuous rail. This efficiency is to be stated both for head up and for head down.

The Society of Industrial Engineers

THE Society of Industrial Engineers met in New York from March 18 to 21 and all who attended their conference were impressed with the fact that a new order of things is upon us. The future will see a greater service rendered by all, and not the least of the burden will fall upon the industrial engineer as he strives for a better understanding between capital and labor.

The session held on Tuesday evening was devoted to Manufacturing and Production Problems. Papers were presented by C. E. Knoeppel, president of C. E. Knoeppel & Co., Industrial Engineers; J. E. Otterson, vice-president of the Winchester Repeating Arms Co., and C. H. Scovell of Scovell, Wellington & Co. Dr. S. W. Stratton also spoke, and in discussing the work of the Bureau of Standards as related to commercial and industrial problems, illustrated his talk with stereopticon views.

The technical session on Wednesday evening was devoted to a consideration of labor problems. The speakers of the evening were Irving A. Berndt, Col. Walter Dill Scott, Magnus W. Alexander, Meyer Bloomfield and Dudley R. Kennedy. Colonel Scott discussed the personnel classification in the Army, and elsewhere in this issue will be found a paper describing in detail this important work.

Engineering Education

The afternoon session of Thursday was given over to a discussion of The Influence of Engineering Education. Dean Schneider, of the University of Cincinnati, was unable to be present and in his place Prof. D. S. Kimball of Cornell occupied the chair. The first speaker of the session was L. P. Alford, editor of *Industrial Management*. Mr. Alford discussed the engineer's place in reconstruction and pointed out that in our present complicated civilization, reconstruction must go beyond medieval ideas. We must do more, he said, than tell the people to "be good." We must show the worker the way and the means.

The chief of the training service of the Department of Labor, H. E. Miles, spoke on Training and Education of Workers. Over one-half the factory workers in the United States, he declared, are giving less than a half-day's fair production. This means a loss of approximately $170,000,000,000. Production, he insisted, must be increased and training is also needed. Mr. Miles also urged manufacturers to coöperate with the U. S. Training Service of the Department of Labor.

Executives as well as workers must be trained and educated, declared F. N. Steinmetz, Jr., president of the Western Efficiency Society. A danger, he said, rests in the possibility of industry continuing to be haphazard. The worker, the major executives and the minor executives must all be educated, and this, he believed, could best be done by the manufacturers themselves, coöperating with the various technical organizations.

The final address of the session was made by C. R. Dooley, on Standards of Engineering Education. As illustrating the work of the Government along these lines, he stated that of all the men who were drafted only 8 per cent had had a high-school education or better, and that the great majority had had no continuity of training. Furthermore, only one-half as many skilled men were found as were needed. The United States Training Service was given 90,000 men and in two months' time had graduated 7000 of them in approximately sixty different trades.

Industrial Engineering as a Profession

An informal banquet was held on Thursday evening, March 20. President L. W. Wallace presided and the topic of the evening was Industrial Education—The Profession. In discussing the subject Professor Kimball declared that the power of modern civilization rested upon the ability to produce worldly goods in enormous quantities. The capacity for production, he stated, was such that he could see no reason why we cannot feed the hungry and clothe the poor as no other people have ever done. People themselves are beginning to form convictions such as these and industry should be considered as the means of supporting human life in the best possible way, but this of course means a radical reorganization of industry if these ideas are to be carried out.

The Scope of Industrial Engineering was discussed by John R. Dunlap, and The Future of Industrial Engineering by Harrington Emerson, Director of Emerson Engineers, New York. Papers were also read by F. C. Schwedtman, vice-president of the National City Bank of New York, and Louis C. Marburg of Marburg Bros., Inc.

Labor-Saving Equipment

The final session was held on Friday afternoon, and the discussion was chiefly concerned with labor-saving equipment as related to maximum production and the elimination of fatigue. Mrs. Frank B. Gilbreth spoke on Fatigue Elimination, and referring to some recent studies by psychiatrists at Boston, emphasized the fact that their work had brought out the resemblance between patients coming to hospitals for psychopathic treatment and many employees in plants. There is, however, she declared, a marked difference between psychopathic fatigue and physical fatigue, and while a worker may not actually be fatigued in body, he may feel so mentally. Mrs. Gilbreth also declared that the psychologist had come into industry to stay and she urged a continuation of the admirable personnel work which had been accomplished by the Adjutant General's Department.

The Need for Labor-Saving Equipment was discussed by Leon I. Thomas, managing editor of *Factory*. About 25 per cent of the alien workmen in the Middle West, he said, are planning to return to their mother countries and such emigration may perhaps produce a shortage of common labor. Furthermore, a new social order is bound to arise and he predicted a great wave of education which, too, will decrease the supply of common labor. It is the duty therefore of the engineer to meet these needs.

J. M. Carmody, in discussing the industrial engineer and the future, considered that an open mind is of primary importance. Engineers, he declared, cannot afford to be behind in the new social order, and particularly industrial engineers, who have a vastly larger field than that of mere welfare work.

During the final session President Wallace announced that sections will shortly be formed at New York, Cleveland, Detroit and Chicago; and that the next conference will be held at Cleveland during the coming autumn.

For a portion of this report Mechanical Engineering is indebted to *The Iron Age*.

In its issue of March 21, *Engineering* (London) published an account of a meeting of the Diesel Engine Users' Association, and announced that, as a result of papers and discussion, the Association has approved and is now circulating among its members the following definitions of Diesel and semi-Diesel engines.

A Diesel engine is a prime mover actuated by the gases resulting from the combustion of a liquid or pulverized fuel injected in a fine state of subdivision into the engine cylinder at or about the conclusion of a compression stroke. The heat generated by the compression to a high temperature of air within the cylinder is the sole means of igniting the charge. The combustion of the charge proceeds at, or approximately at, constant pressure.

A semi-Diesel engine is a prime mover actuated by the gases resulting from the combustion of a hydrocarbon oil. A charge of oil is injected in the form of a spray into a combustion space open to the cylinder of the engine at or about the time of maximum compression in the cylinder. The heat derived from an uncooled portion of the combustion chamber, together with the heat generated by the compression of air to a moderate temperature, ignites the charge. The combustion of the charge takes place at, or approximately at, constant volume.

NECROLOGY

JAMES NISBET HAZLEHURST

Major James N. Hazlehurst, a prominent member of the engineering profession of Atlanta, Ga., died at Brussels, Belgium, February 9, 1919, at 55 years of age. Early in June, 1917 he was commissioned Major of Engineers and assigned to the staff of Major-General Wood, Commander of the Department of the Southeast, as water supply officer of that department. When in September of that year General Pershing cabled for 11 expert engineers, Major Hazlehurst was one of the number chosen to go overseas, serving as first assistant to the officer in charge of the water supply section for six months at General Headquarters, S. O. S., Toms. He was made water-supply officer for Base No. 6 in October, his territory extending from the Riviera to the Italian frontier. Late in January he was assigned to the American Commission to negotiate peace and as Director of the Division to estimate damage to buildings at Brussels, his death occurring while on this assignment.

He was author of a number of technical articles and also a book entitled Towers and Tanks. Major Hazlehurst was very active in technical affairs, taking a leading part in the organization of the Affiliated Technical Societies of Atlanta. He became a member of our Society in 1916.

JOSEPH W. HENDERSON

Joseph W. Henderson, chief of the Bureau of Smoke Regulation, Pittsburg, Pa., died on December 19, 1918. Mr. Henderson was born in Millbrook, Ontario, Canada, on February 22, 1869, and was educated in the schools of Jackson, Mich. He was formerly connected with the Griffin Wheel Co., Chicago, the Maryland Car Wheel works, Baltimore, and the Butler Car Wheel Co., Butler, Pa. He was also vice-president of the Gulick, Henderson Co., New York.

Mr. Henderson was a member of the American foundrymen's Association, the Railway Club of Pittsburg, and the Chamber of Commerce of Pittsburg. He became a member of the Society in 1916.

WILLIAM THOMAS COYLE

William T. Coyle, of the engineering department of the U. S. Naval Experimental Station, New London, Conn., died on December 18, 1918, of pneumonia.

Mr. Coyle was born in Hartford on January 11, 1887, and was educated in the public and high schools of that city. In 1905 he started work for the Sterling Blower Co., Hartford, as detailer, designer and draftsman on heating, ventilating and dust-carrying systems. From 1907 to 1909 he was connected with the Pope Manufacturing Co., Hartford, as draftsman. His next position was with the Dwight Slate Machine Co., also located in Hartford, as a designer of drill presses, gear cutters, marking machines, etc. In 1910 he became connected with the Bullard Machine Tool Co., Bridgeport, as a designer of boring mills, roughing lathes, etc.

William T. Coyle

After four years with this company he became special engineer for the Putnam Machine Co., Fitchburg, Mass., where his work dealt with the development of a new line of boring mills. From 1915 to 1917 he was with the Winchester Repeating Arms Co., New Haven, as designer of equipment and assistant chief draftsman, when he again returned to the Putnam Machine Co., until October, 1917. At that time he became associated with the Deane Machine Co., Fitchburg, as secretary and mechanical engineer. In the summer of 1918 he was called to the Naval Experimental Station.

Mr. Coyle became an associate-member of the Society in 1918.

FREDERICK LESTER LANE

Frederick L. Lane, works manager of the McCambridge Co., Philadelphia, died on March 6, 1919. Mr. Lane was born on March 6, 1856, in St. Johnsbury, Vt., and was educated in the schools of Springfield, Mass. He was formerly connected with the Chapman Valve Manufacturing Co., Springfield, as superintendent, and up to the early part of the present year held the position of mechanical superintendent with the Haines, Jones & Cadbury Co., Philadelphia. Mr. Lane became a member of the Society in 1915.

LOUIS H. MARTELL

Louis H. Martell, president of the Martell Packings Co., Elyria, Ohio, died on January 31, 1919. Mr. Martell was born in Tusket, Nova Scotia, Canada, on February 26, 1864. He was educated in Mt. Clemens, Mich., serving a three-years' apprenticeship with the Michigan Central Railroad, Jackson, Mich. He was later employed by the Boston, Revere Beach and Lynn Railroad and also served as an engineer on coast-wise steamers.

He was also connected with W. B. Merrill & Co., Boston, and under his management the Pitt Manufacturing Co. was organized. In 1908 he became associated with the Metallic Packing & Manufacturing Co. Mr. Martell became a member of the Society in 1906.

STEPHEN PAUL HOSKINS

Stephen Paul Hoskins, 319 Infantry, A. E. F., was killed in action on November 2, 1918, in one of the battles of the Argonne Forest and lies buried near the little town of Imecourt.

Lieutenant Hoskins was born on May 22, 1891, in Erie, Pa. He received his education in the grade schools of Pennsylvania and West Virginia, later attending the West Virginia Wesleyan College and the West Virginia University. He was graduated from the latter in 1914 with the degree of B. S. in mechanical engineering. The year following his graduation he was assistant in mechanical drawing in the University, and later instructor in machine design and mechanical drawing.

Lieut. Stephen P. Hoskins

He left this position to become efficiency engineer with the research division of the Westinghouse Electric & Manufacturing Co., Pittsburg, Pa., where he remained until June, 1916. An attack of inflammatory rheumatism made it necessary for him to sever temporarily his business connections and upon his recovery he entered the service at Camp Lee, Petersburg, Va., in October, 1916. He was recommended for the Third Officers' Training Camp and just before leaving for France was graduated as second lieutenant. He was later promoted to first lieutenant for bravery on the field and just prior to his death was recommended for promotion to the grade of captain and for the Distinguished Service Cross.

Lieutenant Hoskins became a junior member of the Society in 1916.

HARRY DREW EGBERT

Harry Drew Egbert was born at Bay Head, N. J., on August 24, 1886, and died of pneumonia on March 23, 1919. He was educated in the Jersey City public schools and in the Newark Academy. He entered Columbia University in 1904 as a sophomore. The year previous to his entrance he spent with his father, Prof. J. C. Egbert of Columbia, in Rome, where the latter was serving as professor of classical literature in the American School of Classical Studies.

Mr. Egbert was graduated from Columbia University in 1907. He then entered the Schools of Applied Science and spent three years in study for the degree of mechanical engineer which he received in 1910. In the summer during his scientific study he attended the course in surveying at Camp Columbia and was an apprentice in different shops where he became familiar with the practical side of his profession.

After his graduation Mr. Egbert became a member of the office force of the Guaranty Construction Co. After two years he was asked to join the staff of the Research Corporation and in connection with this organization he became an expert on electrical precipitation and was the author of many articles on this subject.

He was a member of the Phi Beta Kappa and Sigma Xi societies. He became a junior member of our Society in 1915 and was secretary of the New York Section, the Executive Committee of which on April 9, 1919, adopted the following resolution:

Resolved, That there be entered upon the minutes the sincere regret of the Committee and their appreciation of his splendid achievements as an engineer and his untiring effort to at all times advance the interest of the Profession, the Society and this Committee.

CHARLES B. RICHARDS

Charles B. Richards, scientist and inventor, for 25 years Higgins Professor of Mechanical Engineering at Yale University and for the last nine years professor emeritus, died on April 20, 1919, in his eighty-sixth year. Professor Richards was a charter member of the Society, having served as manager 1880-1882 and as vice-president, 1888-1890. A more extended biographical sketch will be published in the June issue of Mechanical Engineering.

CHARLES H. MANNING

Capt. Charles H. Manning, for many years prominent in engineering circles in New England, died at Manchester, N. H., on April 1, 1919, in his seventy-fifth year. Captain Manning became a member of the Society in 1884 and was elected to Honorary Membership in 1913, having served as manager 1892-1895 and as vice-president 1895-1897. In the June issue of Mechanical Engineering a more extended account of Captain Manning's life and activities will appear.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by May 15 in order to appear in the June issue.

CHANGES OF POSITION

William A. Blackburn has severed his connections with the Bryant Manufacturing Company, Chicago, Ill., as works manager, and has assumed the position of general manager of the Gray Motor Company, Detroit, Mich.

F. W. Cleveland, formerly assistant superintendent of equipment, Pratt and Whitney Company, Hartford, Conn., has accepted a position with the Illinois Watch Company, Springfield, Ill., in the capacity of equipment engineer.

Arthur C. Whatley, formerly marine draftsman, Bethlehem Shipbuilding Corporation, Bethlehem, Pa., is now in the employ of the Union Oil Company of California, Los Angeles, Cal.

W. H. Diefendorf of Syracuse, N. Y., has resigned his position as chief engineer and director of the New Process Gear Corporation, and is now with the Weeks-Hoffman Company of the same city.

John J. Eason has resigned his position as manager of the Havana Iron Works and the Havana Dry Dock Company at Havana, Cuba, and has accepted a position with the U. S. Shipping Board, Emergency Fleet Corporation, Ship Construction Division, Philadelphia, Pa.

Lewis A. Belding, who for the past two years has been assistant professor of mechanical engineering at Stevens Institute of Technology, Hoboken, N. J., is now associated with the Thomas A. Edison interests at Orange, N. J., in the power service division, as service engineer.

Charles Eisler, for about five years with the Westinghouse Lamp Company, Bloomfield, N. J., as chief designer and engineer in charge of the equipment, designing and development departments, has resigned and has become associated with the recently organized Save Electric Corporation, Brooklyn, N. Y., in the capacity of superintendent of the equipment, designing and development departments.

Kenneth Lydecker, formerly engineer with the Standard Oil Company of New Jersey, has become associated with The White Company, Cleveland, Ohio.

Alfred W. Kimmel, until recently mechanical engineer, Airplane Engineering Department, Bureau of Aircraft Production, McCook Field, Dayton, Ohio, has assumed the duties of general manager of the newly opened eastern office of the Charles M. Kelso Company, Inc., in Utica, N. Y.

Ralph B. Kennard has become affiliated with the engineering department of the New Jersey Zinc Company, Palmerton, Pa. He was until recently connected with the Niagara, Lockport and Ontario Power Company, Buffalo, N. Y., in the capacity of chief draftsman.

Louis W. Sipley, formerly with the Midvale Steel and Ordnance Company, has become affiliated with the Electric Storage Battery Company, of Philadelphia, Pa., in the capacity of sales engineer.

William L. DeBaufre has resigned from the Naval Engineering Experiment Station, Annapolis, Md., and has assumed the duties of designing engineer with the Precision Instrument Company, Detroit, Mich.

J. W. Brussel, formerly superintendent of the Wright-Martin Aircraft Corporation, Long Island City, has accepted a position as factory manager of the Dyneto Electric Corporation, Syracuse, N. Y.

Walter H. Hall has accepted the position of plant engineer with the Champion Ignition Company, Flint, Mich. He was formerly connected with the Remington Arms Union Metallic Company, Swanton, Vt., as works engineer.

E. D. Walen, until recently associate physicist, Bureau of Standards, Washington, D. C., has assumed the duties of manager of the Textile Research Company, Boston, Mass., which has recently been organized by textile manufacturers for the conduct of research or to have research conducted for them along textile lines.

William Stewart Ayars has left the employ of the U. S. Shipping Board where he had been senior performance engineer, Division of Ship Construction, Philadelphia, Pa., and has entered the employ of the Pusey and Jones Company, Wilmington, Del., as chief estimator.

Lloyd D. Gilbert has accepted the position of chief engineer with the Sandusky Cement Company, Cleveland, Ohio. He was formerly chief engineer and superintendent with the Southwestern Portland Cement Company at Victorville, Cal., and also engineered the El Paso plant for the same company.

I. Tornberg, formerly assistant chief draftsman, R. Hoe and Company, New York, has become associated with the Wood Newspaper Machinery Corporation, Plainfield, N. J., in the capacity of engineer.

ANNOUNCEMENTS

K. G. Walker has become affiliated with the Atlas Company, of Lincoln, N. J.

Capt. Philip F. Miller, Ordnance Department, U.S.A., has been discharged from the Army and has become connected with the New York sales office of the A. S. Cameron Steam Pump Works, New York.

Eugene E. Maher has resigned from the district sales managership of the Terry Steam Turbine Company, Hartford, Conn., and has opened offices in Chicago, Ill. He will handle sales and construction of lines of centrifugal, triplex and steam pumps, and engines.

Barzillai G. Worth, vice-president and general manager of Walter Kidde and Company, Inc., New York, has been elected treasurer of the Monmouth Chemical Company, which produces potassium chlorate electrolytically, using processes and apparatus developed under Mr. Worth's direction and whose manufacturing is technically supervised by Walter Kidde and Company, Inc. A contribution to the war was the development by this organization for the Monmouth Chemical Company of a special bromate free chlorate surpassing the German standard, which was adopted by the Ordnance Department to eliminate the causes for ammunition failures reported to Congress in the early stages of the war by Secretary Baker.

Reuben Hill, Major, Ordnance Department, U. S. A., has received his discharge from the service and has accepted the position of chief engineer with the Pratt and Whitney Company, Hartford, Conn.

George E. Harris, for the past year First Lieutenant, U.S.A., assigned to the Bureau of Aircraft Production, Finance Department, has become connected with the Hawkridge Brothers Company, Boston, Mass., in the capacity of director of sales. Mr. Harris has been engaged in the steel business, in both operating and selling ends, for the past 20 years.

A. L. Kershaw has accepted a position with the Electric Auto-Lite Corporation, of Toledo, Ohio.

A. B. Taggart, formerly secretary and treasurer of the Advance Machinery Company, has gone into business in Toledo, Ohio, under the firm name of Toledo Glue Appliance Company, as a designer and manufacturer of glue heaters. Mr. Taggart was connected with the Advance Machinery Company for about seven years, disposing of his interest there last July to enlist. His new company will specialize as consulting engineers in agglutinants and methods of preparing them for use.

Major C. E. Whipple has been honorably discharged from the U. S. Army and has returned to his duties as general manager and treasurer of the New York Central Iron Works Company, Hagerstown, Md.

W. H. Kniskern has become connected with the engineering division, nitrate products department, of the General Chemical Company, New York.

George L. Lubbert has resigned his position of chief operating engineer, Filtration Plant, Baltimore City Water Department, and is now engaged in the electrical and mechanical engineering and contracting business with office in Baltimore, Md.

F. J. Ryan, general manager of the American Metallurgical Corporation, Philadelphia, Pa., was elected to the position of vice-president and treasurer, also continuing as general manager.

T. W. Ransom, chief inspector for the Emergency Fleet Corporation, has resigned, and on April 1 resumed his own offices in San Francisco, as consulting engineer.

Henry M. Leps has assumed the position of general superintendent for the Kanawha Manufacturing Company, Charleston, W. Va.

Herbert M. Hill has accepted a position with the Paper Utilities Corporation, New York, in the capacity of mechanical engineer.

Carl Ehrmann has severed his connection as chief engineer of the Oklahoma Petroleum and Gasoline Company, Tulsa, Okla., and has opened offices as consulting engineer in the same city.

Dean E. Foster, Secretary of the recently organized Mid-Continent Section of the Society, on April 1 severed his connection with Cosden and Company to enter consulting practice with F. P. Peterson, under the firm name of Frank P. Peterson Company, Tulsa, Okla.

Thomas Chester has opened an office in St. Louis, Mo., in order to manage the St. Louis district office for the American Blower Company. He was until recently connected with the New York office of the company as special representative, handling the Navy business.

Lieut. F. C. Holmgren, who returned from France in February, has taken the management of the Philadelphia branch of the Trailmobile Company. Lieutenant Holmgren has been identified with the automobile and truck industry since 1905.

Clarence O. Hartman has become associated with the Atlas Portland Cement Company, Northampton, Pa. He was, until recently, connected with the Engineering Bureau of the U. S. Government at Washington, D. C.

B. J. Cline has assumed the position of factory manager of the Templar Motors Corporation, Cleveland, Ohio.

Captain Harvey S. Benson has left the Ordnance Department, U.S.A., and has assumed the duties of factory manager of the Caskey Dupree Manufacturing Company, of Marietta, Ohio.

Major Leiferts Hutton, M.C., son of the late Prof. Frederick R. Hutton, Past-President and Honorary Secretary of the Am. Soc. M.E., has been cited for exceptional energy and zeal in the performance of all duties as assistant division surgeon and for courage displayed under fire in the forward areas. This throughout the service of the division in Belgium and in France.

Leo Mayer, for nine years construction engineer for the Otis Elevator Company at New York and Cleveland, and more recently with the Bureau of Construction and Repair, Navy Department, has resigned his position with the Navy Department and has established himself as sales engineer with offices in Boston, Mass., specializing in conveying and material handling machinery. Mr. Mayer also represents the Standard Conveyor Company, of St. Paul, Minn.

John R. Battle has opened an office in Philadelphia, Pa., as consulting industrial oil and mechanical engineer. He was, until recently, mechanical engineer and Philadelphia manager of Swan and Finch Company, of New York.

Lieut. Wallace J. Cross, Engrs. U.S.A., has been discharged from service and has accepted the position of assistant mechanical engineer with the Watson Engineering Company, Cleveland, Ohio.

Major James Guthrie, U.S.A., Ordnance Engineering, has returned to Cleveland and reopened his consulting engineering office. Major Guthrie put aside his practice in order to enter active service at the beginning of the war, completing a staff assignment in Washington and serving eight months as engineering manager of the Michigan Ordnance District.

Lieut. Richard S. Austin, of Brooklyn, N. Y., a member of the 166th Aero Squadron, was cited by General Pershing for valor during the Argonne-Meuse offensive.

APPOINTMENTS

Harold J. Williams, First Lieutenant, Ordnance Department, U.S.A., who for the last 16 months has been attached to the Mobile Gun Carriage Section of the Artillery Division, Washington, D.C., has resigned his commission in the Ordnance Department to accept the appointment of engineer for the Beacon Falls Rubber Shoe Company, Beacon Falls, Conn., and associated interests. Prior to his entry into service, Mr. Williams was consulting and mechanical engineer, and was also on the teaching staff of Pratt Institute, Brooklyn, N. Y.

AUTHORS, ETC.

Miss Kate Gleason, the first woman to be elected a member of the Am. Soc. M.E., addressed the Rochester Engineering Society at its weekly meeting on March 17 at the Hotel Seneca. She described engineering features noted on her recent visit to the Orient.

Major W. B. Gregory has been appointed representative of the Louisiana Engineering Society at the conference of Engineering Societies to be held in Chicago, April 23 to 25.

LIBRARY NOTES AND BOOK REVIEWS

Aeronautical Engines. A Critical Survey of Current Practice with Special Reference to the Balancing of Inertia Forces. By Francis Jogn Kean. Second edition. Spon & Chamberlain, New York. 1918. Cloth, 5 x 8 in., 101 pp., 49 illus., 31 pl.. $2.50.

This book consists of a course of ten lectures given during 1915 to men of the Royal Naval Air Service and the Royal Flying Corps, designers and engineering students.

The Design and Construction of Dams. Including Masonry, Earth, Rock-fill, Timber and Steel Structures, also the principal types of Movable Dams. By Edward Wegmann. Sixth edition, revised and enlarged; 1918 reprint revised. John Wiley & Sons, Inc., New York, 1918. Cloth, 9 x 12 in., 529 pp., 157 pl., 24 tables, $6.

The present volume is a reprint, with revisions, of the sixth (1911) of this well-known and popular treatise. A special feature of the book is the detailed information given concerning important dams in all parts of the world.

Compressed Air Plant. By Robert Peele. Third edition. John Wiley & Sons, Inc., New York, 1919. Cloth, 6 x 9 in., 485 pp., 246 illus., 54 tables, $4.25.

This edition has undergone a thorough revising, and a number of chapters have been rewritten and several have been expanded, while old material has been condensed or omitted. The volume describes current practice in the construction and operation of compressors and discusses the applications of compressed-air drilling, pumping and hauling, with special reference to mine service.

Cotton Facts. (Edition of October, 1918.) Compilation from Official and Reliable Sources of the Crops, Receipts, Exports, Stocks, Home and Foreign Consumption, Visible Supply, Prices, and Acreage of Cotton in the United States and Other Countries for a Series of Years. Also Cotton-Mill Statistics of the United States, Europe, India, etc., the Reports of Condition of Growing Cotton Crops, issued by the U. S. Department of Agriculture and the Cotton Acreage and Yield of each State and County in the South according to the U. S. Census. Edited by Carl Geller. Shepperson Publishing Co., New York. 1918. Cloth, 4 x 7 in., 240 pp., 1 por., $1.

This volume is the forty-third annual issue. In a book of pocket size, it presents the statistics needed by cotton merchants, manufacturers and growers, as indicated in the title.

Gasoline and Kerosene Carburetors. Construction—Installation—Adjustment. A simple, comprehensive Treatise for Practical Men, explaining all principles pertaining to Carburetors for all Types of Internal-Combustion Engines intended to operate on Liquid Fuels such as Gasoline, Kerosene, Benzol and Alcohol. By Victor W. Pagè. The Norman W. Henley Publishing Co., New York, 1919. Cloth, 5 x 8 in., 219 pp., 89 illus., $1.50.

A handbook for operators of internal-combustion engines. Explains in non-technical language the principles of carburetors, the usual modern types and the method of adjusting and repairing them.

Graphic Charts for the Business Man. By Stephen Gilman. La Salle Extension University, Chicago, 1918. Paper, 6 x 9 in., 62 pp., 56 illus.

A pamphlet showing the value of charts in presenting statistical data, and describing some of the varieties used in business.

Hendrick's Commercial Register of the United States for Buyers and Sellers. With which has been incorporated The Assistant Buyer. Especially devoted to the Interests of the Electrical, Engineering, Hardware, Iron, Mechanical, Mill, Mining, Quarrying, Chemical, Railroad, Steel, Architectural, Contracting and kindred Industries. A complete and reliable annual Register of Producers, Manufacturers, Dealers and Consumers connected with the aforesaid Industries. S. E. Hendricks Co., Inc., New York, (copyright 1918). Cloth, 8 x 10 in., 2381 pp. $10.

This register of producers, manufacturers, dealers and consumers connected with the engineering and industrial activities of the country has been carefully revised and corrected. The firms included are listed alphabetically and also carefully classified. A section containing trade names and brands, with the names of manufacturers, forming a convenient ready reference list for purchasers, is a distinctive feature.

Mill and Cyanide Handbook. Comprising Tables, Formulæ, Flowsheets, and Report Forms, compiled and arranged for the use of Metallurgists, Mill-men and Cyanide Operators. By W. A. Allen. J. B. Lippincott Co., Philadelphia, 1918. Cloth, 4 x 7 in., 128 pp. $2.

The author has tabulated the physical, chemical and mechanical data needed by mill-men, in a volume of convenient size, well indexed. A glossary of mill and cyanide terms is included.

Modern Shipbuilding Terms Defined and Illustrated. Including a Series of Photographs showing the Progressive Steps of Construction, together with an Appendix on Electric Welding. By F. Forrest Pease. Lippincott Co., Philadelphia, (copyright 1918). Cloth, 5 x 8 in., 143 pp., 68 pl. $2.

This work contains a glossary of the more common words and phrases used in building a steel ship; a list of shipyard trades and the duties performed by each; a series of instruction charts on electric welding; a list of symbols used on plans and parts; a description of the Isherwood system of shipbuilding; directions for the use of acetylene, hydrogen and oxygen for cutting and welding; and a select list of books on ship construction and equipment. The plates illustrate the construction of a ship by the usual methods, the construction of the "fabricated" ship, and the tools, machines and installations.

Simplified Navigation for Ships and Aircraft. A Text Book based upon the Saint Hilaire Method. By Charles Lane Poor. The Century Co., New York, 1918. Cloth, 126 pp., 10 illus., 7 charts, 4 tab. $1.50.

This work is an attempt to explain in non-technical language and without the use of complicated mathematics the principles which form the basis of modern methods of navigation. Particular attention is given to aerial navigation.

A Study of Engineering Education. Prepared for the Joint Committee on Engineering Education of the National Engineering Societies. By Charles Riborg Mann. (Carnegie Foundation for the Advancement of Teaching, Bulletin number 11). New York, 1918. Paper, 8 x 10 in., 139 pp.

The purpose of this report is to examine the fundamental question of the right methods of teaching and of the preparation of young men for the engineering professions. In the light of the fifty years of experience of the engineering colleges of the United States, an effort has been made to suggest the pedagogic basis of the course of study intended to prepare young men for the work demanded of the engineer to-day, without losing sight of the point of view of the teacher, the engineer, the manufacturer and the employer. A limited number of typical schools were visited and studied by Professor Mann and the views of the whole engineering profession throughout the country were ascertained in the course of the investigation. It is the hope of the Committee that the report will awaken wide interest because of its applicability, and that its influence on engineering education will be beneficial.

The Silk Directory. Davison's Silk Trade. Office Edition. A Directory of the Silk Manufacturers of the United States and Canada, including Silk Dyers, Finishers and Printers; Manufacturers' Agents; City Offices and Salesrooms of Silk Mills; Dealers in Raw, Thrown, Spun and Artificial Silk; Waste; Cotton, Tinsel and Worsted Yarns; Silk Jobbers and Retailers and a Classified Directory of All Manufacturers of Silk Goods. Twenty-third annual edition. Davison Publishing Co., New York. (Copyright, 1918.) Cloth, 8 x 6 in., 778 pp. $3.50.

The directory includes dyers, finishers, printers, manufacturers' agents, city offices and salesrooms of mills, dealers, jobbers, retailers and manufacturers. These are given in lists classified primarily by occupation and secondarily by location. The lists have been carefully revised and enlarged by the addition of new establishments.

Success in the Small Shop. By John H. Van Deventer. Second edition. Published by American Machinist. (McGraw-Hill Book Co., Inc., sole selling agents), New York, 1918. 1/4 cloth, 9 x 11 in., 137 pp., illus. $1.75.

A series of articles, 50 in number, dealing with the problems of small machine shops, that appeared originally in the *American Machinist*. The articles discuss economic conditions, management, equipment, methods, etc., and are intended to be of practical help to owners and workmen.

Handbook of Chemistry and Physics. Compiled by Charles D. Hodgman, assisted by Melville F. Coolbaugh and Cornelius E. Senseman. The Chemical Rubber Co., Cleveland, Ohio, 1918. Flexible cloth, 4 x 7 in., 557 pp., $2.50.

This compilation is intended to present in one volume of convenient size a comparatively comprehensive reference book for the use of chemists and physicists. The seventh edition has been enlarged by one hundred pages, which contain a revision of a table of the physical constants of organic compounds. This table now includes about two thousand substances. Various minor additions and corrections have been made throughout the work.

Heaton's Annual. 15th Year, 1919. Published by Heaton's Agency, Toronto, Canada. Cloth, 5 x 7 in., 512 pp. (including advertisements), $1.50.

A handbook of condensed commercial and industrial information on Canada. Describes the natural and commercial resources of the provinces, and industrial opportunities in the towns and cities. Much general information of use to visitors and business men is included.

A Manuel of Chemical Nomography. By Horace G. Deming. The University Press, Champaign, Ill., 1918. In two parts, text and tables, $1.25.

The Noman (part one) is a nomographic reckoner, devised by the author for the graphic solution of various arithmetical problems. Multiplication, division, powers, roots and logarithms can be treated by the eighteen charts, with an average error of one part in four or five thousand.

The manual describes the method of using the Noman and gives specific examples of its application to the solution of chemical problems and indicates the kinds of calculations in which it is most useful.

Model Making. Including Workshop Practice, Design and Construction of Models. A Practical Treatise for the Amateur and Professional Mechanic. Gives Instructions on the Various Processes and Operations Involved in Model Making and the Actual Construction of numerous Models, including Steam Engines, Speed Boats, Guns, Locomotives, Cranes, etc. Lathe Work, Pattern Work, Electroplating, Soft and Hard Soldering, Grinding, Drilling, etc., are also included. Edited by Raymond Francis Yates. The Norman W. Henley Publishing Co., New York, 1919. Cloth, 6 x 9 in., 390 pp., 303 illus., 1 pl., $3.

The author hopes that his book will promote interest in model engineering in this country, and will also give a correct impression of its value as a recreation.

Nineteenth Year Book. Of the Rubber Association of America, Inc., New York, 1918. Paper, 6 x 9 in., 119 pp.

Contains list of members, constitution and annual report for 1918.

Public Utility Rate Fixing. Comments on Current Problems Pertaining to Public Utilities and to Rate Fixing. By C. E. Grunsky. Technical Publishing Co., San Francisco, 1918. Cloth, 6 x 9 in., 169 pp., 5 charts, 2 pl., $2.50.

A reprint of a number of articles originally contributed to the *Journal of Electricity*, written in the hope that they may prove helpful in determining fair rates for the output of public utilities and in prescribing methods of procedure when rates are to be fixed; and that they may assist in the solution of some of the economic problems which arise in the readjustment to peace conditions.

Radiation, Light and Illumination. By Charles Proteus Steinmetz. Compiled and edited by Joseph LeRoy Hayden. Third edition. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6 x 9 in., 305 pp., 127 illus., 1 pl., 14 tables, $3.

A series of twelve experimental lectures, most of which were delivered in 1908-1909, with the exception of two lectures on Light Flux and Distribution, and Light Intensity and Illumination. The treatment is non-mathematical and discusses the subjects in plain language. This edition is apparently a reprint of the preceding ones.

The Shipbuilding Industry. By Roy Willmarth Kelly and Frederick J. Allen, with an introduction by Charles M. Schwab. Houghton Mifflin Co., Boston and New York, 1918. Cloth, 6 x 8 in., 303 pp., 61 pl. $3.

The primary purpose of this volume, as stated by the authors, is to describe and interpret for the general public, as well as for those employed in the shipyards, our war emergency shipping program and the task of the shipbuilders. It is also hoped that the book will help those who wish to prepare themselves for executive positions and those considering shipbuilding or naval architecture as a possible life calling.

Steam Engine Troubles. A Practical Treatise for the Engineer, telling how to locate and remedy troubles with a Steam Engine. Cylinders, Valves, Pistons, Frames, Pillow Blocks and other Bearings, Connecting Rods, Wristplates, Dashpots, Reachrods, Valve Gears, Governors, Piping, Throttle and Emergency Valves, Safety Stops, Flywheels, Oilers, etc., are all treated. By H. Hamkens. The Norman W. Henley Publishing Co., New York, 1919. Cloth, 5 x 8 in., 284 pp., 276 illus., $2.50.

A simple account of the troubles which may arise in steam-engine operation, the causes and the proper remedies. Intended for the power-plant engineer. Based on a series of articles published in *Power*.

THE ENGINEER AS A CITIZEN

(*Continued from page 451*)

engineers have placed a stamp more marked than any other group of men. Among the every day questions in legislation and administration are many engineering problems. The engineer's knowledge is therefore needed in the public affairs of today, and the engineering profession must recognize the duty of making available to Society its peculiar training and experience.

Public activity, to be effective, must be carried on by groups rather than by individuals. A prerequisite of any worth-while public profession or activity, therefore, is the organization of the whole engineering profession in such a manner that it may be mobilized in city, state and nation for the purpose of giving representative opinion, appointing representative individual engineers or committees and securing united action.

Even in professional activities better organization of the profession is desirable because there no longer exist clear lines of demarkation between the spheres of interest of individual groups of engineers and because many activities, like standardization and research, can be carried on effectively only if undertaken jointly. There are in this country several hundred engineering societies having in common many aims and purposes and duplicating efforts to a large degree.

Organization and coöordination of efforts is not possible without previous crystallization of aims and purposes of individual societies. Four large national engineering societies have appointed special committees for the purpose of securing such crystallization.

This meeting, attended by members of engineering and scientific societies having a total metropolitan membership of about 15,000, feels strongly that more coöperation among all groups of engineers and among all existing engineering societies is essential. It is therefore—

Resolved, that all engineering societies of this country, not yet having committees on development, be asked to appoint such committees with instructions to undertake a survey of the aims and purposes of their respective associations and to coöperate with corresponding committees of other engineering and similar societies; and it is further

Resolved, that a copy of these resolutions be sent to every engineering society in this country.

Following the passing of this resolution, the chair appointed Mr. Castle secretary of the meeting and instructed him to carry out the order of the resolution.

Before the meeting adjourned Spencer Miller offered the following resolution, which was unanimously adopted:

Resolved, that the representatives of the local sections of the various engineering bodies here present tonight recommend to their bodies that these bodies shall send a delegate to a common engineering conference for the purpose of discussing, formulating and reporting back to their respective bodies a Code for Professional Conduct, with a view of its adoption by all the engineering bodies involved as the common code for the engineering profession.

THE ENGINEERING INDEX

Published Monthly by The American Society of Mechanical Engineers

The Engineering Index was Founded in 1884 by the Association of Engineering Societies; Published from 1895 to 1919 by The Engineering Magazine Company; and Acquired January 1919 by The American Society of Mechanical Engineers

THE following pages form a descriptive Index to articles on engineering and related subjects in current periodicals. In its preparation the Society's engineering staff regularly examines all of the technical journals and society publications received by the Engineering Societies Library, which form one of the greatest and most complete collections of scientific periodicals in the world, comprising upward of 1100 distinct publications in some ten languages. Cross-references are freely introduced in the Index, and in all cases where the titles of articles are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC COPIES OF ARTICLES LISTED

THE Society is prepared to supply photostatic copies (white printing on brown background) of any of the articles listed. Copies of the periodicals themselves, or clippings of articles, cannot be supplied.

Price of each print (up to 11 x 14 in. in size), 25 cents plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Those holding coupon books for clippings formerly issued by The Engineering Magazine Company may use the coupons in payment for photostatic prints. In ordering, state plainly

(1) Page number of Index on which item appears
(2) Title of article
(3) Name of periodical.

Orders should be sent to

HARRISON W. CRAVER, *Director,*
Engineering Societies Library,
29 West 39th Street, New York City.

Mechanical Engineering

AIR MACHINERY

Compressors

Up-to-date Practice in Compressor Maintenance. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 569-572, 4 figs. Methods of inspection and overhauling. Details of compressor overhauling and testing bench.

Fans

Centrifugal Fans and Their Application to Gas Engineering Practice, Frank S. Townsend. Gas Jl., vol. 145, no. 2906, Jan. 21, 1919, pp. 116-118 and discussion pp. 118-119, 15 figs. Elementary theory of fan; description of two types of centrifugal fan (radial flow and mixed flow); discussion of efficiency of fan, methods of driving, and regulation; examples of recent practice in application of fan plants. Paper before Midland Junior Gas Assn.

See also MECHANICAL ENGINEERING, Lubrication (Air Compressors); MINING ENGINEERING, Mines and Mining (Dust Sampling).

FORGING

Heavy Forgings

Making and Heat-treating Heavy Forgings, Franklin D. Jones. Machy., vol. 25, no. 7, Mar. 1919, pp 583-590, 12 figs. General practice of Tacony Ordnance Corporation in production of ingots and forgings for 155- and 240-mm. guns.

Turned Forgings

Making Accurate Turned Forgings. Iron Trade Rev., vol. 64, no. 13, Mar. 27, 1919, pp. 815-818, 8 figs. Details of manufacturing operations at plant of company specializing on finished marine and machine forgings.

FURNACES

Davis "Revergen" Principle of Firing

The Davis "Revergen" Principle of Firing Furnaces with Town Gas. Metal Industry, vol. 14, no. 9, Feb. 28, 1919, pp. 169-171, 2 figs. Demonstrations made of system in annealing steel billets at 870 deg. cent.; billet heating up to 1000 deg. cent. and high-temperature test. Also in Gas Jl., vol. 145, no. 2911, Feb. 25, 1919, pp. 385-387, 2 figs.

Industrial Furnaces

Industrial Furnaces (Fours Industriels), A. Bigot. Chimie & Industrie, vol. 2, no. 1, Jan. 1, 1919, pp. 30-36, 8 figs. Classification of various types; their uses and equipment.

Oven and Muffle Furnaces

Industrial Oven and Muffle Furnaces and Their Method of Operation, C. M. Walter. Metal Industry, vol. 14, no. 10, Mar. 7, 1919, pp. 183-185. On theoretical maximum temperatures of combustion of different fuels to be obtained in economical operation of furnaces.

FOUNDRIES

Brass Foundry

Materials and Chemicals Used in Brass Foundry Practice—IV, Charles Vickers. Brass World, vol. 15, no. 3, Mar. 1919, pp. 69-71, 2 figs. History, properties, appearance, physiological action and commercial use of the substances commonly used in brass founding.

Some Principles Involved in Melting Metals—IV, Charles Vickers. Brass World, vol. 15, no. 3, Mar. 1919, pp. 73-75. Effect of heat upon metals; action of zinc and copper; casting of yellow brass.

British

British Foundries Undergo Change, H. Cole Estep. Iron Trade Rev., vol. 64, no. 13, Mar. 27, 1919, pp. 819-823, 2 figs. Survey of conditions in Great Britain, with reference to recent improvements in shop methods.

Malleable Foundry

Uses Electric Furnace in Malleable Foundry, F. L. Prentiss. Iron Age, vol. 103, no. 9, Feb. 27, 1919, pp. 537-543, 8 figs. Features of Cleveland plant of Nat. Malleable Castings Co., designed for making castings by Kranz triplex process.

Nickel Alloy Castings

Casting Nickel Silver—a Copper-Nickel-Zinc Alloy, R. V. Hutchinson. Metal Industry, vol. 14, no. 9, Feb. 28, 1919, pp. 161-162, 1 fig. Method of packing a crucible with nickel silver.

Patternmaking

Patternmaking Methods, Joseph A. Shelly. Machy., vol. 25, no. 7, Mar. 1919, pp. 631-634, 9 figs. Typical examples of pattern work and methods used in general practice. First article.

Pouring Metal

Foundry Puzzles and Their Solution, J. G. Horner. English Mechanic, vol. 109, no. 2816, Mar. 14, 1919, pp. 85-86. Remarks on static load and dynamic action at time of pouring due to inrush of molten metal.

Sand

Ferruginous and Other Bonds in Molding Sands, P. G. H. Boswell. Brass World, vol. 15, no. 3, Mar. 1919, pp. 81-84. Foundry practices followed in Great Britain, France, Belgium and Germany. Paper read before Am. Foundrymen's Assn.

The Practical Analysis of Molding Sand, U. Albert Hayes. Iron Age, vol. 103, no. 12, Mar. 20, 1919, pp. 739-741, 2 figs. Selection according to physical qualities and the nature of the work is advocated; sieve tests.

See also MECHANICAL ENGINEERING, Heating and Ventilation (Foundry Ventilation), Standards and Standardization (Brass and Brass Foundries).

FUELS AND FIRING

Absorption of Gases by Coal

Absorption of Gases by Coal, S. H. Katz. Queensland Govt. Min. Jl., vol. 20, Feb. 15, 1919, pp. 60-62. Experimental research with air and with an atmosphere of nitrogen.

Blending

The "Sandwich" System of Fuel Blending, E. W. L. Nicol. Gas Jl., vol. 145, no. 2906, Jan. 21, 1919, pp. 113-115, 3 figs. Apparatus which permits the mixing of various qualities of solid fuel as they are fed to burners. Also in Natl. Engr., vol. 23, no. 4, Apr. 1919, pp. 161-164, 2 figs.

Chart for Comparing Values of Different Sizes of Coal

Chart for Finding True Value of One Size of Coal. Black Diamond, vol. 62, no. 12, Mar. 22, 1919, p. 318, 1 fig. Gives value of one size in terms of values of other sizes.

Coal Analysis

Natural Solid Fuels (Contribution à l'étude des combustibles naturels solides, Roger Hartman. Société Industrielle de l'Est, bul. 144, Jan. 1919, pp. 7-18, 3 figs. Method of analyzing a sample of coal and calculating into its calorific value. Based on notes published by the Association Alsacienne des Propriétaires d'Appareils à vapeur.

Coal Problem

Coal and Other Fuels and Substitutes, Alexander Ross. Ry. Gaz., vol. 30, no. 6, Feb. 7, 1919, pp. 202-205. Address before Retired Ry. Officers' Soc.

Gas and Oil Fuels

See Producer Gas, page 10*a*; items under INDUSTRIAL TECHNOLOGY; and Oil, under MINING ENGINEERING.

Lignites

Combustion of Lignites and High-Moisture Fuels, T. A. Marsh. Power, vol. 49, no. 14, Apr. 8, 1919, pp. 525-527, 5 figs. Types of stoker adaptable to burning lignites containing up to 35 per cent moisture. Predrying is considered impractical. Also in Elec. World, vol. 73, no. 6, Feb. 8, 1919, pp. 265-267, 5 figs.

Notes on Lignite, Its Characteristics and Utilization, S. M. Darling. Universal Engr., vol. 29, no. 1, Jan. 1919, pp. 27-34. Concerns particularly the utilization and storage of lignite.

Peat

Peat, Lignite and Powdered Coal, F. Parkman Coffin. Steam, vol. 23, no. 3, Mar. 1919.

Powdered Fuel

Powdered Fuel for Hammersmith. Elec. Times, vol. 55, no. 1430, Mar. 13, 1919, pp. 168-169, 2 figs. Layout of Holbeck system of powdered fuel for firing boilers.

Pulverized Coal Burners Versus Stokers, Joseph T. Foster. Elec. World, vol. 73, no. 10, Mar. 8, 1919, pp. 474-475, 1 fig. Comparative freight charges on low- and high-grade fuel. Chart showing maximum amount that can be paid for pulverized coal to make it comparable with a given stoker coal.

Success in Combustion of Powdered Coal, W. G. Wilcox. Black Diamond, vol. 62, no. 12, Mar. 22, 1919, pp. 328-329. Velocity of combustion; importance of mixing with air.

Smokeless Combustion

Combustion and Smokeless Furnaces, Jos. W. Hays. Steam, vol. 23, no. 2, Feb. 1919, pp. 42-46. Points out what are termed undesirable features of the various types of smokeless furnace.

Storage

Storage of Fuel and Spontaneous Combustion, S. H. Pudney. Official Proc. Can. Ry. Club, vol. 17, no. 2, Feb. 1919, pp. 15-21 and (discussion) 22-23. Losses due to storage and causes for spontaneous combustion, verified by author's experience. Also in Contract Rec., vol. 33, no. 13, Mar. 26, 1919, pp. 291-293.

Spontaneous Combustion of Bituminous Coal in Storage (La conservation en tas des charbons bitumineux et les dangers de leur combustion spontanée), Ch. Vallet. Industrie Electique, vol. 28, no. 640, Feb. 25, 1919, pp. 73-76. Experiments, observations and recommendation. From paper before Inst. Mar. Engrs.

Deterioration in Value During Storage, H. C. Porter and F. K. Ovitz. Black Diamond, vol. 62, no. 12, Mar. 22, 1919, pp. 322-324, 10 figs. Summary of tests to determine heat-value losses from various forms of storage.

Wood

The Use of Wood for Fuel. U. S. Dept. of Agriculture, Bul. 753, Mar. 10, 1919, 40 pp., 2 figs. Suggestions as to proper use of wood resources to prevent recurrence of fuel shortage such as occurred during winter of 1917-1918.

See also MINING ENGINEERING, Coal and Coke (Ash Yield, Calorific Value); RAILROAD ENGINEERING, Locomotives (Powdered Fuel).

FURNACES

See MECHANICAL ENGINEERING, Heat Treating (Heating Furnaces), Refractories (Ovens and Kilns).

GAGES

Checking

Checking Gages, Herman L. Wittstein. Factory, vol. 22, no. 3, March 1919, pp. 456-457, 3 figs. Forms for keeping gage inspection.

Gage Systems

A Practical Ring, Plug, and Snap Gauge System. Machinery, vol. 13, no. 328, Jan. 9, 1919, pp. 400-401, 10 figs. System designed to meet requirements in interchangeable manufacture.

Profile Gages

Contour of Profile Gauges. Machinery, vol. 13, no. 337, Mar. 13, 1919, pp. 649-655, 31 figs. Principles involved and procedure followed in developing gaging systems for interchangeable manufacture, based upon experience of Pratt & Whitney Co. Third article.

Thread-Measuring Wires

The Manufacture of Standard Thread Measuring Wires, Fred. R. Daniels. Machy., vol. 25, no. 7, Mar. 1919, pp. 606-607, 4 figs. Table of values used for determining error in thread angle by the three-wire system.

HANDLING OF MATERIALS

Ash Handling

Raw Material and Ash Handling Equipment, Robert June. Brick & Clay Rec., vol. 54, no. 6, Mar. 25, 1919, pp. 507-509, 3 figs. Principles of power-plant requirements. Ninth article.

Foundry Trucking

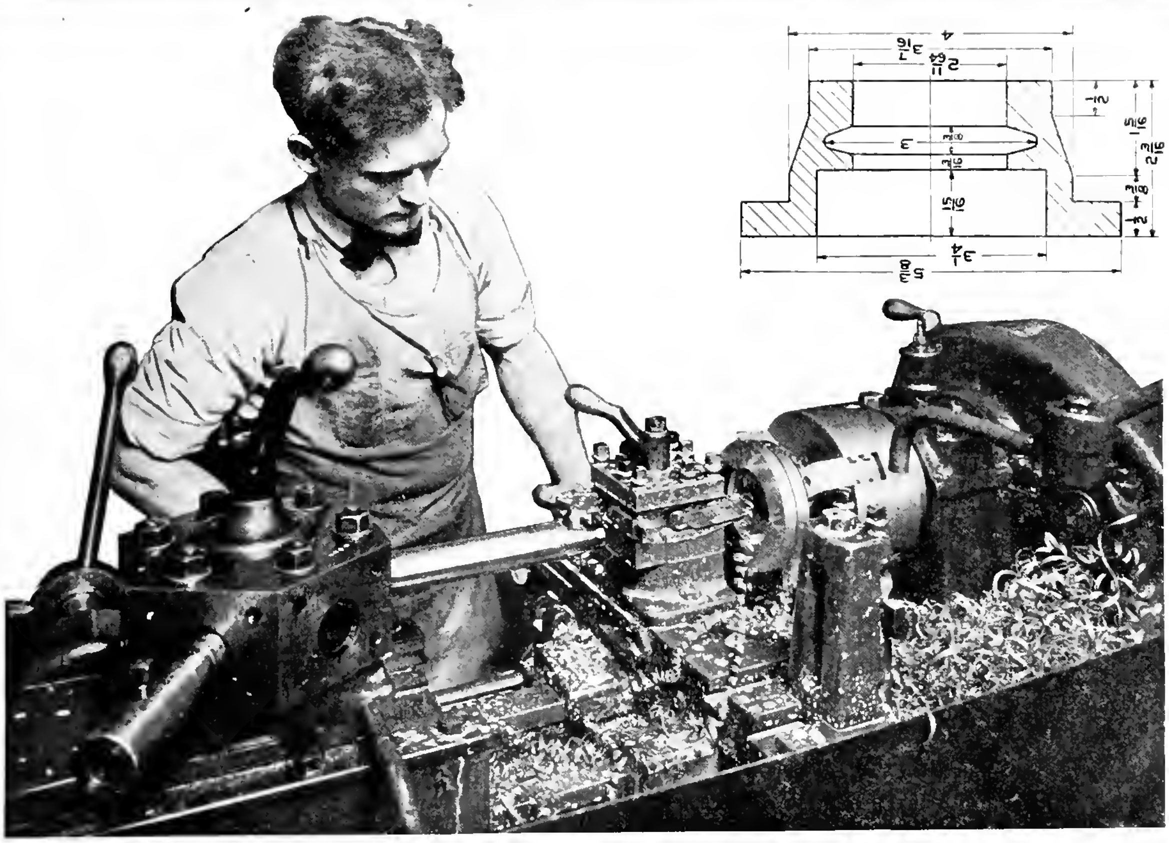
Foundry Built around a Shop Truck. Iron Age, vol. 103, no. 10, Mar. 6, 1919, pp. 603-606, 10 figs. Material-handling system at new plant of Peerless Foundry, Cincinnati.

Materials

Handling Materials, F. T. Buell and Edward R. Cole. Factory, vol. 22, no. 3, March 1919, pp. 470-471, 8 figs. Seven plans as used in two plants.

Shell Shops

Handling Devices in British Shell Shops. Eng. & Indus. Management, vol. 1, no. 5, Mar. 13, 1919, pp. 157-161, 20 figs. Handling ap-



Value of the Square Turret

THIS shows the amount of material removed and how well the many operations on these tough power sprocket clutches were finished on the No. 4 Universal Screw Machine. The hexagon turret was used only for boring. The square turret, loaded to capacity with cutters, did the rest with the aid of its eight power cross and longitudinal feeds.

For Work Too Complicated or Ordinary Screw Machines

The special features of the No. 4 Universal (in this case the unusual use for the square turret) adapt them to a wide range of work too complicated for ordinary screw machines or turret lathes.

SEND FOR DETAILS
Turret Lathes and Screw Machines
from ⅝ in. x 4 in. to 4½ in. x 44 in., Maximum Swing 21½ in.

HEAT-TREATING

Engine Parts

Heat Treatment of Steel for Small Petrol Marine Engines. Engineer, vol. 127, no. 3294, Feb. 14, 1919, pp. 159-160, 1 fig. On the building of light "chasers" in America.

Gun Forgings

Electric Heat Treatment of Gun Forgings. C. E. Wright. Iron Age, vol. 103, no. 11, March 13, 1919, pp. 673-678, 12 figs. Installation at naval gun plant of Tioga Steel & Iron Co., Philadelphia. It is intended to use this plant for commercial use.

Heating Furnaces

Practical Pointers on Heating Furnaces. George J. Hagan. Am. Drop Forger, vol. 5, no. 3, Mar. 1919, pp. 142-144. Deals with heating furnaces in general for treatment of both light and heavy stock. Before Engrs. Soc. Western Pa.

Annealing and Heating Furnaces Fired by Town Gas. Engineering, vol. 107, no. 2774, Feb. 28, 1919, pp. 272-276, 8 figs. Leading feature is incorporation of regenerators for heating the air supply before it enters the furnace by means of waste gases from the furnace. Development by Technical Section of the Davis Furnace Co.

Steel

Heat Treatment of Steels (Le traitement thermique des aciers). Métallurgie, vol. 51, no. 12, Mar. 19, 1919, pp. 646-647. Its influence on the quality of products.

HEATING AND VENTILATION

Air Sampling

The Effect of Sunlight on Air. William J. Mauer. Heat & Vent. Mag., vol. 16, no. 3, Mar. 1919, pp. 27-32, 7 figs. Report on laboratory tests to determine proper technique in handling air samples.

Central-Station Combination Heating Plants

Advantage of the Combination Central Station Heating Plant. John C. White. Heat. & Vent. Mag., vol. 16, no. 3, Mar. 1919, pp. 33-37. Recommendations put forth by Bureau of Mines for combining central-station heating systems with steam-power plants.

Equivalent Temperatures, Steam-Hot Water

Equivalent Temperature of Guaranteed Steam and Hot Water Heat. Henry N. Dix. Am. Architect, vol. 115, no. 2254, Mar. 5, 1919, pp. 358-360, 6 figs. Formula and charts.

Factory Heating

Factory Heating. Alfred G. King. Domestic Eng., vol. 86, no. 11, Mar. 15, 1919, pp. 466-468, 5 figs. Hot water heating with forced circulation.

Foundry Ventilation

Foundry Ventilation. Iron Age, vol. 103, no. 10, Mar. 6, 1919, p. 610, 3 figs. Effect of roof design and heating systems on air circulation.

Hot-Water Central Heating Plant

Designing Data as Applied to a Large Hot Water Heating Plant. George E. Reed. Heat. & Vent. Mag., vol. 16, no. 3, Mar. 1919, pp. 17-26, 11 figs. Plant for high school of five buildings. "Unit" system followed in design and construction.

Industrial Buildings

The Mechanical Equipment of Industrial Buildings—II. Charles L. Hubbard. Power, vol. 49, no. 10, March 11, 1919, pp. 362-365. Remarks on selections of type of prime mover, systems of power distribution and methods of heating and ventilating.

Laws

Proposed Michigan Law on Furnace Heating. Metal Worker, no. 2360, Mar. 21, 1919, pp. 372-374. Bill to regulate and control the installation of warm-air heating plants.

Temperatures, Indoor and Outdoor

Tests for Heating Plants in Mild Weather. Henry N. Dix. Metal Worker, no. 2360, Mar. 21, 1919, pp. 365-367, 7 figs. Charts of temperature indoors with varying outdoor temperatures.

Vacuum Heating

Care of Heating and Ventilating Equipment—VIII. Harold L. Alt. Power, vol. 49, no. 9, March 4, 1919, pp. 306-308, 11 figs. Vacuum-heating systems.

See also MINING ENGINEERING, Mines and Mining (Ventilation).

HOISTING AND CONVEYING

Bucket Hoist

Bucket Carrier System (Benne preneuse continue, pour la manutention des matières pondéreuses). Génie Civil, vol. 74, no. 9, Mar. 1, 1919, pp. 171-175, 3 figs. Chain belt with buckets moves continuously over material to be handled; buckets discharge on iron channel where material descends by gravity.

Cable Breakage

Breaking of Cable in Protection Shaft. Robert Dunn. Coal Age, vol. 15, no. 11, March 13, 1919, pp. 489-491, 2 figs. Tests said to indicate that breaking of rope was due to inadequate lubrication, particularly in hemp center.

Grab Bucket, Self-Discharging

Barnard's Self-Discharging Grab. Engineering, vol. 107, no. 2772, Feb. 14, 1919, pp. 200-202, 11 figs. Improvements made in design since last description published in issue of April 17, 1914, p. 524.

See also MARINE ENGINEERING, Auxiliary Machinery (Luffing Cranes).

HYDRAULIC MACHINERY

Flow of Water

The Flow of Water in Large Pipes and Tunnels. Frederick J. Mallett and Alfred A. Barnes. Engineering, vol. 107, no. 2774, Feb. 28, 1919, pp. 288-291, 14 figs. Traces out inconsistencies met with in many of the older formulæ, and sets out the features that in practice determine the ultimate capacity of water mains. Abstracts of two papers read before Instn. Civil Engrs.

Pelton Wheels

A Pelton Wheel Driven Centrifuge. F. J. Broadbent. Engineering, vol. 107, no. 2771, Feb. 7, 1919, pp. 161-164, 10 figs. Design based on theory outlined in article entitled Static Torque Experiments on a Pelton Wheel, Eng. Sept. 11, 1914.

Tidal Power

"Blue Coal." Sci. Am. Supp., vol. 87, no. 2253, Mar. 8, 1918, pp. 156-157 and 160, 9 figs. Efforts that have been made to utilize energy of waves and tides. From Larousse Mensuel, Paris.

Wave Propagation

Determination of the Velocity of Propagation of Waves in Forced Conduits (Détermination de la vitesse de propagation des ondes dans les conduites forcées). C. Camichel. Technique Moderne, vol. 10, no. 12, Dec. 1918, pp. 537-544, 20 figs. Explains by means of de Sparre formulæ anomalies which have been pointed out by engineers in experimental determination of velocity of propagation of waves; writer believes that the apparent variations of this velocity are explicable and disappear altogether if a correct experimental method is followed.

INTERNAL-COMBUSTION ENGINES

Carburation

The Carburation Temperature of Oil Mixtures. C. A. Norman. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, pp. 490-491, 1 fig. Method of determining temperature necessary to keep in a permanent state of vaporization any oil fraction contained in a carburized mixture.

Diesel-Engine Injection

Solid Injection Versus Air-Injection. Motorship, vol. 4, no. 4, Apr. 1919, pp. 35-37, 6 figs. Technical aspect of subject in its bearing on future design and construction of high-compression marine oil engines for merchant and naval ships. Second installment.

Diesel Engines

McIntosh & Seymour Marine Diesel Engine. Power, vol. 49, no. 14, Apr. 8, 1919, pp. 528-531, 4 figs. Description of a four-stroke cycle directly reversible engine.

Hot-Bulb Engines

The British Two-stroke Motor. Engineer, vol. 127, no. 3295, Feb. 21, 1919, pp. 182-183, 3 figs. Gear of directly reversing hot-bulb engine.

Radial Engines

The Enfield-Allday Five-cylinder Radial Engine. Autocar, vol. 42, no. 1221, Mar. 15, 1919, p. 357, 1 fig. Engine in which air cooling is effected by means of aluminum fins and forced draft.

Truck and Tractor Engines

Three Hinkley Engines Built Around Class "B" Design. Automotive Industries, vol. 40, no. 11, Mar. 13, 1919, pp. 587-589, 6 figs. Models for 1 to 6-ton 1½- to 2½-ton trucks and tractors drawing 1 to 4 plows.

Valves

Small Inlet Valves Satisfactory in Overhead Valve Design—II. L. H. Pomeroy. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, pp. 471-475, 5 figs. Tests made with two engines of same size, one having a valve-in-head design and the other an L-head with valves side by side in valve pocket. Tests are said to have proven that specific fuel consumption is largely independent of r.p.m. and torque for 50 to 60 per cent of maximum hp. Paper before Instn. Automobile Engrs.

Characteristics of a High-Grade Standardized Engine. J. H. W. Kerston. Automotive Industries, vol. 40, no. 10, Mar. 6, 1919, pp. 527 and 549. Effect of increasing valve size on efficiency and smoothness of run.

See also MECHANICAL ENGINEERING, Motor-Car Engineering (Carburetor Testing, Carburetors); AERONAUTICS, Engines.

LUBRICATION

Air Compressors

Correct Lubrication of Air Compressors. H. V. Conrad. Iron Age, vol. 103, no. 12, Mar. 20, 1919, pp. 753-754, 1 fig. Cylinder temperatures and physical tests of oils given as guide for selecting lubricant. Paper prepared for Compressed Air Soc. Also in Eng. & Min. Jl., vol. 107, no. 9, Mar. 1, 1919, pp. 392-394, 1 fig.

Colloidal Phenomena

A Problem in Lubrication. W. B. Hardy. Jl. Soc. Chem. Indus., vol. 38, no. 2, Jan. 31, 1919, p. 7T. Colloidal phenomena in lubrication.

Lubricants

Lubrication and Lubricants. G. R. Rowland. Jl. Am. Soc. Naval Engrs., vol. 31, no. 1, Feb. 1919, pp. 97-138, 7 figs. Definition, classification, testing, refining and selection.

See also MECHANICAL ENGINEERING, Motor-Car Engineering (Lubrication).

MACHINE ELEMENTS AND DESIGN

Bearings

On Proportioning Engine Bearings. Otto M. Burkhardt. Automotive Industries, vol. 40, no. 12, Mar. 20, 1919, pp. 651-655, 10 figs. Analysis of crank-bearing loads in a 4-cylinder, 3-bearing truck engine under different conditions of operation.

Cams

Cam Design and Construction. Franklin de R. Furman. Am. Mach., vol. 50, no. 13, Mar. 27, 1919, pp. 581-586, 13 figs. Introduction; types of cams described. First article.

Gears

Toothed Gearing. Joseph Chilton. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, p. 92. Manufacture and design of spur, helical, bevel, and worm gearing for transmitting motion between shafts the axes of which are either parallel or at right angles to each other. Paper before North-East Coast Instn. Engrs. & Shipbuilders.

Pistons

Pistons and Their Treatment. Motor Traction, vol. 28, no. 733, Mar. 19, 1919, pp. 246-248, 10 figs. Suggestions in regard to detaching the piston; testing the relative truth of pistons with connecting rods.

Springs

Minimum Number of Combined Springs (Sur le nombre minimum de spiraux associés). Jules Andrade. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 3, Jan. 20, 1919, pp. 139-141. On regulation of pendulums and balance wheels for exact chronometric work.

MACHINE SHOP

Broaches

Determining the Number of Broaches to Use. Machinery, vol. 13, no. 335, Feb. 27, 1919, p. 599, 1 fig. Chart.

FIRING THAT IS • DIFFERENT •

WITH the RILEY STOKER the coal is fed—the fire cleaned—the ash discharged, *continuously* and *automatically*. All done without waste or effort, efficiently and economically.

It is not only the things the RILEY STOKER does but the way it does them. For instance, when steam is wanted quickly and time is precious, you can get this steam instantly and economically by increasing the motion of the grates.

With the first turn of the cranks the grates start moving—the whole fuel bed is thrown into action. There is no watching nor waiting—poking nor slicing—the stoker responds instantly and in two or three minutes the boiler will be operating at 200 or 250% of rating.

It is this kind of flexibility that saves not only for the central station but for the industrial plant.

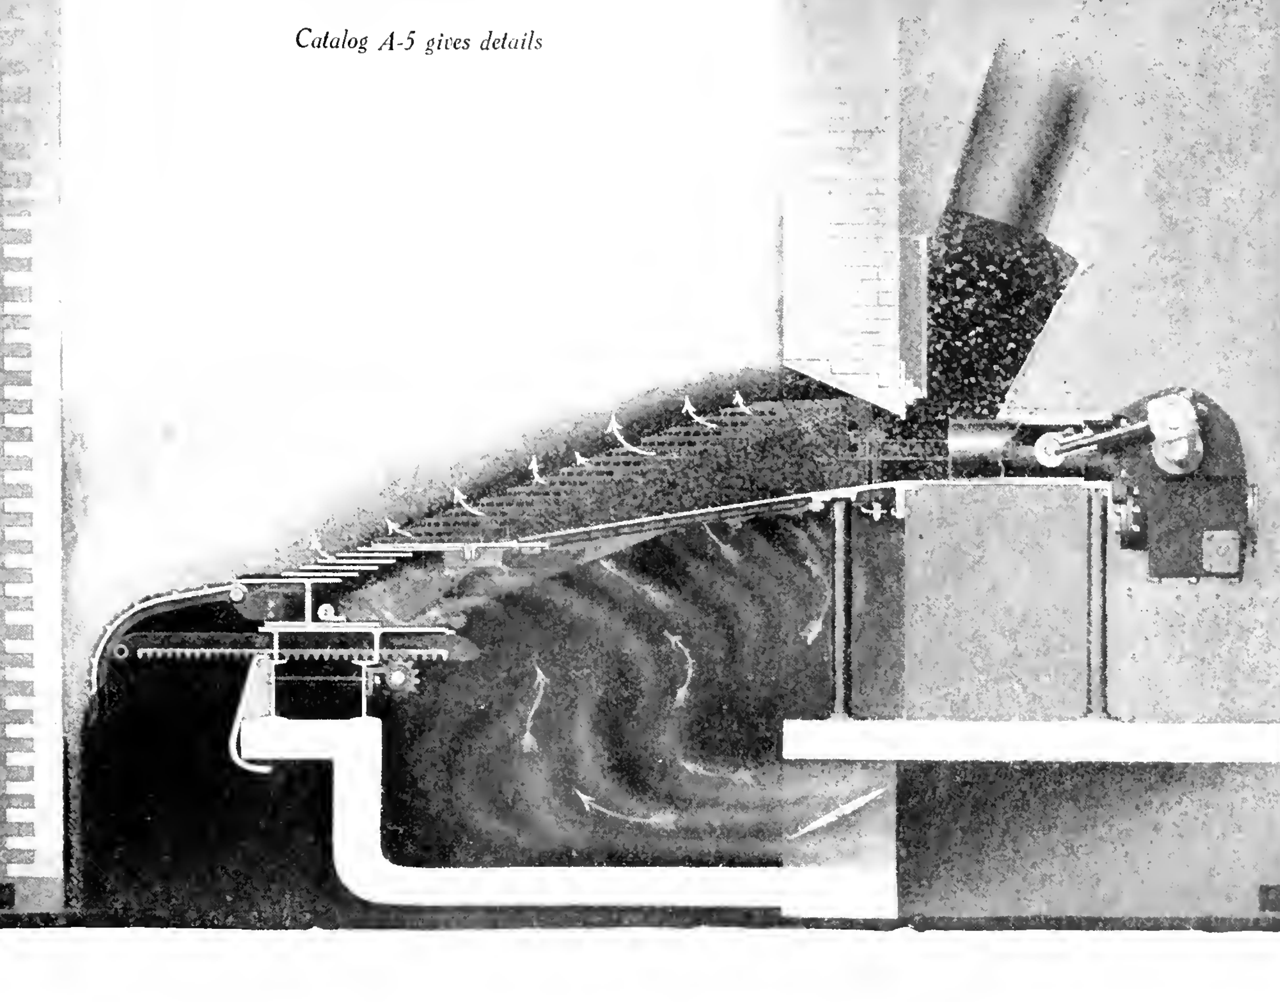
Catalog A-5 gives details

RILEY UNDERFEED STOKERS

TRADE MARK Rx REGISTERED

Sanford Riley Stoker Co.,
Worcester, Massachusetts

British Licensees: Erith's Eng. Co., Ltd., London
French Licensees: Erith, Leroy & Cie., Paris, France



Crankshaft Repairs

Recent Crankshaft Repairs. Iron Age, vol. 103, no. 13, Mar. 27, 1919, pp. 812-813, 3 figs. Six-throw crankshaft made from steel billets by thermit process.

Electric Drive

Electric Drive for Punching Shaping and Slotting Machines. C. E. Clewell. Am. Mach., vol. 50, no. 10, Mar. 6, 1919, pp. 439-444, 12 figs. Discussion on basis of machines in which duty cycle throughout given operations consists of two directions of motion.

Motor Drive as Viewed by Machine Builders and Motor Manufacturers. C. E. Clewell. Am. Mach., vol. 50, no. 11, March 13, 1919, pp. 475-478, 7 figs. Result of canvassing opinions of various machine-tool builders and electric-motor manufacturers.

Machine Tool Drives: Motors and Controllers. H. W. Tice. English Mechanic, vol. 109, no. 2816, Mar. 14, 1919, pp. 88-89, 2 figs. Service records of motors and machine tools controlled in Lehigh plant of Bethlehem Steel Co. (To be continued.)

Foundations

Foundations for Various Types of Planers. Terrell Croft. Can. Machy., vol. 21, no. 2, Jan. 9, 1919, pp. 29-34, 16 figs. Suggests use of leveling blocks and recommends concrete as best material.

Grinding and Sizing

Grinding and Sizing Diagrams. Alfred T. Fry. Min. & Sci. Press, vol. 118, no. 10, March 8, 1919, pp. 324-327, 5 figs. Suggests method of drawing curve to compare and use results obtained while making tests of grinding efficiency of a given machine under varied conditions.

Cylinder Grinding. Franklin D. Jones. Machy., vol. 25, no. 7, Mar. 1919, pp. 615-621, 12 figs. Discussion of advantages of finishing cylinder bores by grinding; machines and auxiliary equipment used; practice in different plants manufacturing engines for automobiles and airplanes. First article.

Roller Bearings

Roller Bearings for Machine Shop Equipment—III. Machinery, vol. 13, no. 335, Feb. 27, 1919, pp. 604-607, 6 figs. Combination radial and thrust roller bearings; roller bearings with staggered rollers; lubrication.

Splitting Piston Rings

Splitting Piston Rings. Jacob Young. Machy., vol. 25, no. 7, Mar. 1919, pp. 590-591, 1 fig. Chart for determining length of section to be cut from piston ring.

Swivel Machining

Machining Front Axle Swivels. A. Thomas. Automobile Engr., vol. 9, no. 124, Mar. 1919, pp. 72-74, 10 figs. Manufacturing operations on swivels made from nickel-steel drop forgings.

Templets

Templets, Jigs and Fixtures. Joseph Horner. Engineering, vol. 107, no. 2772, Feb. 14, 1919, pp. 197-199, 13 figs. Describes various types. Twentieth article.

Test-Piece Manufacture

The Rapid Production of Test Pieces. Can. Machy. vol. 21, no. 9, Feb. 27, 1919, pp. 206-207, 9 figs. Making test pieces from shell.

Workshop Practice

Modern Workshop Practice—VI. W. Wilson. Commonwealth Engr., vol. 6, no. 6, Jan. 1, 1919, pp. 173-180, 15 figs. Science of quick repetition. Deals with modifications in lathes through omission of parts not required for the particular work to be done.

See also RAILROAD ENGINEERING, Shops.

MACHINERY, METAL-WORKING

Arresting Motion for Presses

Automatic Arresting Motion for Power Presses. Engineer, vol. 127, no. 3293, Feb. 7, 1919, p. 135, 2 figs. Mechanism can be applied to type of machine in which a flywheel revolves freely on its shaft until a positive connection is established between the two parts by a convenient device.

Die-Sinking Tools

A discussion on Die Room Conditions. F. J. Rau. Am. Drop Forger, vol. 5, no. 3, Mar. 1919, pp. 126-128, 4 figs. Sketches of die-sinking tools.

Gear-Tooth Rounding Machine

Walker Automatic Gear Tooth Rounding Machine. Automotive Industries, vol. 40, no. 12, Mar. 20, 1919, pp. 648-650, 5 figs. Design to round meshing edges or to remove burrs left by cutters or hobs.

Lathe

Engine Lathes for Precision Work. Iron Trade Rev., vol. 64, no. 10, Mar. 6, 1919, pp. 633-637, 8 figs. How various lathe parts in the process of making are routed through the grinding, planing, milling, turning and assembling departments of a machine-tool plant in Cincinnati.

Niles Heavy Driving Wheel Lathe at Crewe Works, London & North Western Railway. Ry. Gaz., vol. 30, no. 7, Feb. 14, 1919, pp. 252-253, 2 figs. Turning tires of express passenger locomotives.

Milling and Gear Cutting on Lathes

Making Milling and Gear Cutting Attachment—1. Robert Mawson. Can. Machy., vol. 21, no. 3, Jan. 16, 1919, pp. 51-53 and 63, 11 figs. Attachment for lathes which performs milling and gear-cutting operations. Various tools and operations used are shown.

Square Bar for Internal Planing

Square Bar for Internal Planing, W. G. D. Machinery, vol. 13, no. 335, Feb. 27, 1919, pp. 600-601, 2 figs. Formulæ and calculations.

Thread-Milling Cutter

The Cycloid Thread-Milling Cutter. Engineer, vol. 127, no. 3294, Feb. 14, 1919, p. 159, 1 fig. Design to overcome "waves" and "flats" on work.

MACHINERY, WOODWORKING

Woodworking Machines

Apparatus for Woodworking and Their Recent Improvements (Les machines-outils pour le travail du bois et leurs récents perfectionnements). E. Gay. Technique Moderne, vol. 10, no. 12, Dec. 1918, pp. 554-563, 29 figs. French types of machines for finishing patterns. (Concluded.)

MACHINERY, SPECIAL

Clock Escapements

Clock Escapements. Engineering, vol. 107, no. 2775, Mar. 7, 1919, pp. 297-298, 2 figs. History of development of present combination. Paper before Roy. Instn.

Drill Sharpener

Drill Sharpener Speeds Up Shipbuilding. Letson Balliet. Mine & Quarry, vol. 11, no. 2, Mar. 1919, pp. 1130-1133, 14 figs. Making of drift bolts, rivets, grab-iron ends, ball stanchions, etc.

Hammer Drills

Hammer Drills—Their History, Design and Operation. Henry S. Potter. Jl. South African Instn. Engrs., vol. 17, no. 6, Jan. 1919, pp. 86-98, 5 figs. Materials of construction; pistons and valves; general features of modern jack hammers; limitations in use of hammer drills for stoping. Second and concluding installment.

Lapping Machine

A Machine for Lapping Precision Gage Blocks. Am. Mach., vol. 50, no. 13, Mar. 27, 1919, p. 613, 1 fig. Design for producing gage blocks of any contour, but having two opposite sides flat and parallel and a definite distance apart.

Routing Machine

Routing Machine of Special Design. Am. Mach., vol. 50, no. 11, Mar. 13, 1919, pp. 491-493, 5 figs. Machine uses tool which is rapidly rotated through several turns in one direction, then reversed and rotated as rapidly and for an equal number of turns in the opposite direction, this cycle of movement being continued so long as may be necessary to complete the operation.

Worm-Wheel Generator

G & E 18-In. Worm Wheel Generator. Automotive Industries, vol. 40, no. 14, Apr. 3, 1919, pp. 746-747, 3 figs. Machine designed for producing worms and worm wheels for trucks, tractors, etc., and adapted for production and experimental work.

See also MINING ENGINEERING, Coal and Coke (Coal-Washing Machinery, Roll Crushers).

MATERIALS OF CONSTRUCTION AND TESTING OF MATERIALS

Aluminum

Aluminum: Its Use in the Motor Industry in England. E. Carey Hill. Metal Indus., vol. 17, no. 3, March 1919, pp. 125-127, 2 figs. Application of aluminum in replacing steel and other metals. Second and last article.

Alternating Stresses, Steel

Premature Rupture of Steel Pieces Subjected to Repeated Stresses (Cause de la rupture prématurée des pièces d'acier soumises à des efforts répetés). Ch. Fremont, Génie Civil, vol. 74, no. 3, Jan. 18, 1919, pp. 47-52, 15 figs. Survey of experiments on formation and extension of fissures. Some deductions in Wöhler's theory are held to be inexact. Also in Comptes rendus des séances de l'Académie de Sciences, vol. 168, no. 1, Jan. 6, 1919, pp. 54-56.

Beams, Reinforced-Concrete

Tests Show High Shears in Deep Reinforced-Concrete Beams. W. A. Slater. Eng. News Rec., vol. 82, no. 9, Feb. 27, 1919, pp. 430-433, 4 figs. Preliminary studies made for Emergency Fleet Corporation's concrete ship work. Higher safety units than those now permitted are advocated.

Bearing Metals

Proper Specifications for Bearing Metals. Alfred A. Greene. Iron Age, vol. 103, no. 14, Apr. 3, 1919, pp. 874-875. Functions of a lining alloy; mixing the component metals; electrically hardened lead.

Brass, Rolled Sheet

Structural Characteristics of Rolled Sheet Brass. Metal Indus., vol. 17, no. 3, March 1919, pp. 121-124, 6 figs. Thermal equilibrium diagrams of various alloys; photomicrographs of cast and annealed brass. (To be continued.)

Brickwork

Tests Determine Strength of Brickwork. W. W. Pearse. Contract Rec., vol. 33, no. 8, Feb. 19, 1919, pp. 151-155, 10 figs. Report of tests carried out at Toronto Univ. in cooperation with City Architect's Dept.

Mortars, Cement-Lime

Compressive Strength of Cement-Lime Mortars. F. A. Kirkpatrick and W. B. Orange. Jl. Am. Ceramic Soc., vol. 2, no. 1, Jan. 1919, pp. 44-64, 9 figs. Determination of factors exerting greatest control over strength of cement-lime mortars. Manner of control expressed by mathematical formula and practical application of results indicated.

Resistance of Materials

The Resistance of Materials. G. S. Chiles and R. G. Kelly. Ry. Mech. Engr., vol. 93, no. 3, March 1919, pp. 123-126, 6 figs. Review of data relative to effect of abrupt changes of section under "static" and "dynamic" tests published by various authorities and results of experiments conducted by writers. (To be continued.)

MEASUREMENTS AND MEASURING APPARATUS

Air-Measuring Instruments

The Determination of the Efficiency of the Turbo-Alternator, S. F. Barclay and S. P. Smith. Elecn., vol. 82, no. 2128, Feb. 28, 1919, pp. 244-246, 3 figs. Suggestions in regard to measuring air volume and temperature; diagrams plotted from pitot tube readings taken at opening of temporary discharge trunk. Before Instn. Elec. Engrs.

Coal-Consumption Meter

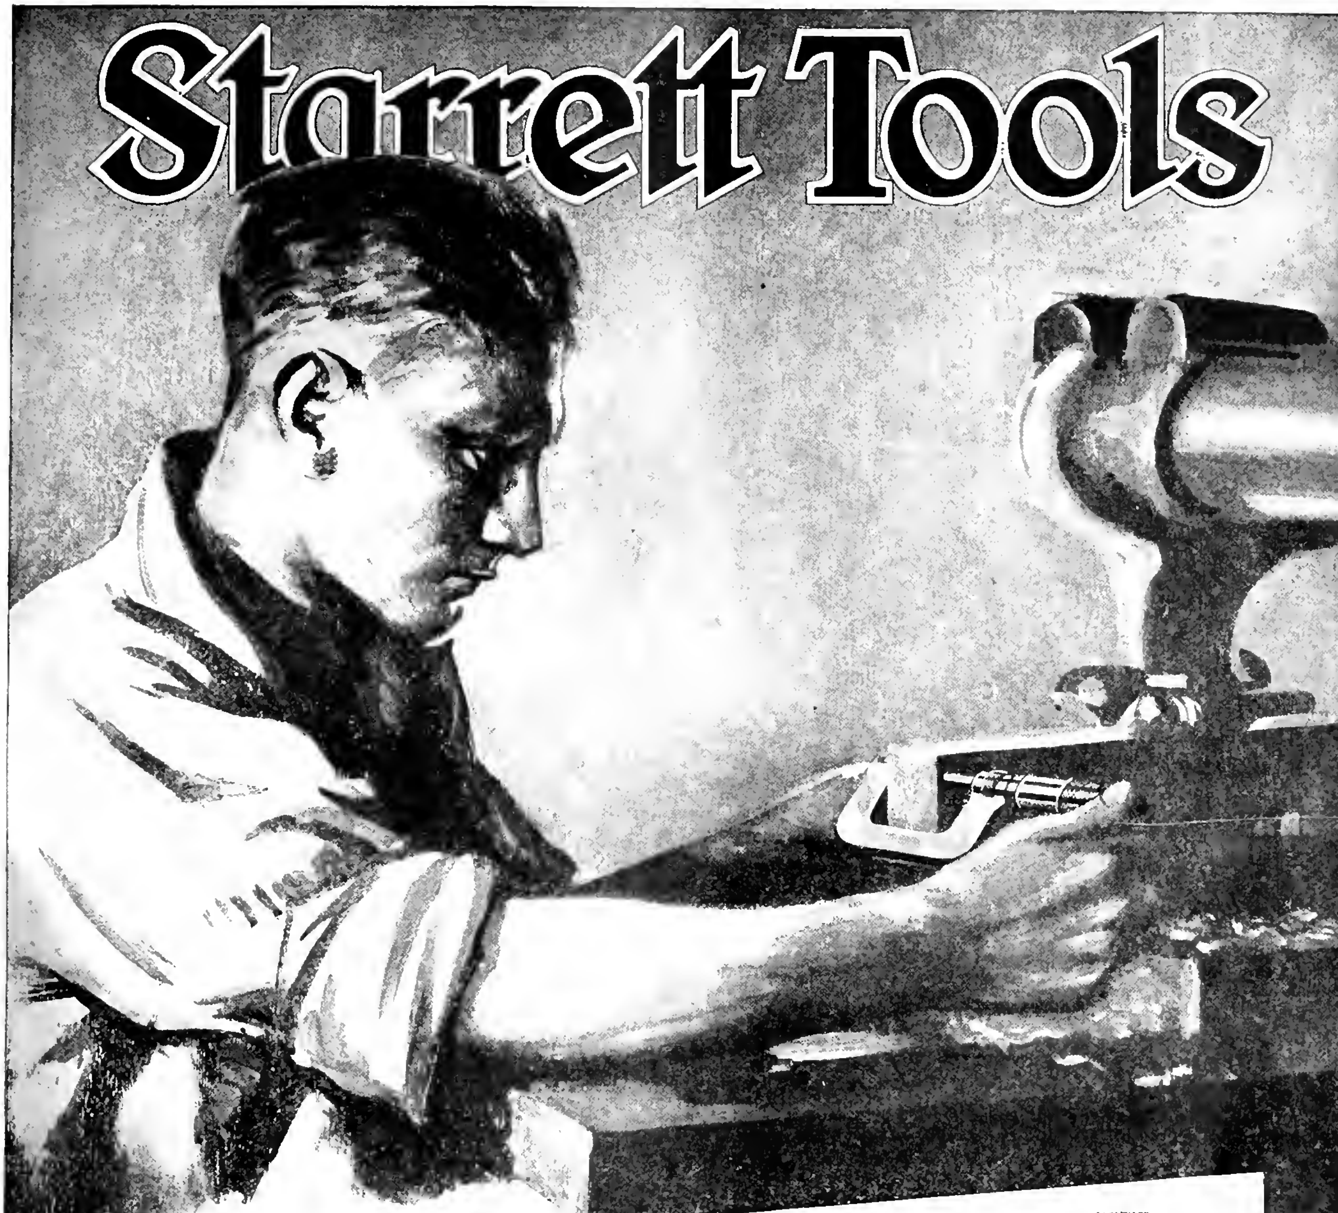
Lea Coal-Consumption Meter (Apparell indicateur-totalisateur de la consommation de charbon, système Lea). P. Letheule. Génie Civil, vol. 74, no. 6, Feb. 8, 1919, pp. 101-105, 18 figs. Registers total consumption by system of levers and pinions operated by motion of stoker and controlled by volume of coal fed into burners. Details of construction and application of apparatus to Stirling and Babcock boilers are given.

Flow Meters

An Automatic Compensating Flow Meter. G. G. Oberfell. Jl. Indus. & Eng. Chemistry, vol. 11, no. 4, Apr. 1, 1919, pp. 294-296, 1 fig. Instrument intended for accurately controlling gas concentration of gas-air mixtures.

Fluid Velocity and Pressure

The Measurement of Fluid Velocity and Pressure, J. R. Pannel. Engineering, vol. 107, nos. 2774 and 2775, Feb. 28 and Mar. 7, 1919, pp. 295-297 and 261-263, 14 figs. Robinson cup anemometer; vane anemometer and other "moving part" instruments. (Continuation of serial). Feb. 28: Pressure tube instruments.



SINCE 1880—

For two generations we have been making fine precision instruments — building them to the Starrett standard—not to a price.

Today the name Starrett is recognized the world over as standard for accuracy. Starrett Tools are helping skilled mechanics produce high-quality work.

Manufac urers of Hack Saws Unexcelled

Athol, Mass.

42-001

Oil-Tank Gaging

Scientific Gauges, B. C. Rinehart. Petroleum Age, vol. 6, no. 3, March, 1919, p. 30, 1 fig. Method of gaging oil tanks.

Standards of Temperature and Means of Checking Pyrometers. Am. Mach., vol. 50, no. 12, Mar. 20, 1919, pp. 541-545, 7 figs. Directions for use of standards; chart showing relation between base-metal thermocouple and net electromotive force.

Paper Tester

The Webb Paper Tester—A New Instrument for Testing Corrugated Fiber Boards, J. D. Malcolmson. Jl. Indus. & Eng. Chem., vol. 11, no. 2, Feb. 1, 1919, pp. 133-138, 6 figs. Comparison with Mullen tester decides writer to prefer Webb machine.

Pyrometers

Checking Pyrometers to Get Results. Am. Drop Forger, vol. 5, no. 3, Mar. 1919, pp. 131-137, 6 figs. Various methods are recommended for different sizes of equipment.

Thermocouples

Calibration of Base-Metal Thermocouples, G. S. Crouse. Eng. & Min. Jl., vol. 107, no. 10, March 8, 1919, pp. 442-444, 1 fig. Describes three methods of calibrating such couples.

Viscosimeters

Standardization of the Saybolt Universal Viscosimeter, Winslow H. Herschel. Department of Commerce, Tech. Papers Bur. Stand., no. 112, 25 pages, 4 figs. Equation for instruments of standard dimensions.

See also MECHANICAL ENGINEERING, Research, (Rolling Mill, Research Laboratory), Air Machinery (Compressors), Machine Shop (Test-Piece Manufacture), Power Plants (CO_2 Recorders); AERONAUTICS, Aerostatics (Schilling Apparatus for Measuring Hydrogen), Instruments; MINING ENGINEERING, Mines and Mining (Dust Sampling).

MECHANICAL PROCESSES

Bakelite Products and Dies

Making Molded Bakelite Products. Machinery, vol. 13, no. 331, Jan. 30, 1919, pp. 481-485, 9 figs. Designing and making dies with provision for heating with steam.

Boilers

Areas of Segments of Boiler Heads, Power, vol. 49, no. 11, March 18, 1919, pp. 402-404, 2 figs. Table of areas of segments of boiler heads to be stayed.

Chains, Cast-Steel

Malleable Plant Proves Versatility. Iron Trade Rev., vol. 64, no. 10, Mar. 6, 1919, pp. 623-629, 12 figs. Adaptation to manufacture of cast-steel anchor chains of plant designed and constructed for malleable foundry.

Gears

The Manufacture and Design of Toothed Gearing, Joseph Chilton. Engineering, vol. 107, no. 2772, Feb. 14, 1919, pp. 202-206, 13 figs. Gearing employed in transmission of motion between shafts whose axes are either parallel or at right angles to each other. (To be continued.) Read at North-East Coast Instn. Engrs. & Shipbuilders.

Pumps

Manufacturing Rotary Suds Pumps. Machinery, vol. 13, no. 328, Jan. 9, 1919, pp. 406-408, 11 figs. Pump manufactured by Brooke Tool Co. is presented as example of interchangeable manufacture.

Rolling Mills

Universal Mill Rolls Strip Steel. Iron Trade Rev., vol. 64, no. 11, Mar. 13, 1919, pp. 691-695. Roughing unit is of massive construction, each housing weighing 42 tons; spring of mill when rolling high-carbon steel is 0.001 in.

Rolling Concrete Reinforcements from Old Rails, W. S. Standiford. Can. Machy., vol. 21, no. 3, Jan. 16, 1919, pp. 59-61 and 65, 5 figs. Design and general layout of roughing and finishing rolls.

Large Rolling Mill Plant. Elec. Rev., vol. 84, no. 2155, Mar. 14, 1919, pp. 283-284, 4 figs. Particulars and illustrations of Siemens 19,000 hp. rolling mill motor. (To be concluded.)

The Government Rolling Mill, Southampton. Engineer, vol. 127, nos. 3296 and 3297, Feb. 28 and Mar. 7, 1919, pp. 191-193 and 217-219, [illegible]. Mill is being employed in melting of scrap metal and is turning out standard Government brass ingots of guaranteed analysis. Mar. 7: Power plant and gas-producer equipment; facilities for handling coal, coke and raw materials; foundry and rolling departments.

Rubber Goods

Railroad Rubber Goods, G. W. Alden. Official Proc. Car Foremen's Assn., Chicago, vol. 14, no. 5, Feb. 1919, pp. 36-71. Growth and properties of crude rubber; manufacture of wrapped ply hose, belting and various kinds of packings.

Sheet Metal Products

Imagination and Sheet Metal Layout Work, F. Scriber. Can. Machy., vol. 21, no. 9, Feb. 27, 1919, pp. 199-202, 10 figs. Examples of bending sheet metal into shape.

Work of Sheet Metal Man in New Industry, W. B. Metzger. Metal Worker, vol. 41, no. 10, Mar. 7, 1919, pp. 302-304, 5 figs. Making apparatus for use in distillation of volatile oils from birch and wintergreen.

Tank Links

Machine Tool Adaptations for the Manufacture of Tank Links. Engineer, vol. 127, no. 3293, Feb. 7, 1919, pp. 120-123, 12 figs. Operations performed on stamping pattern of links for moving tracks of tanks.

Tubes, Seamless

Making Seamless Tubes. Iron Trade Rev., vol. 64, no. 4, Jan. 23, 1919, pp. 259-264, 11 figs. Piercing and cold-drawing processes as followed at plant of Standard Seamless Tube Co.

Textiles

Back-Filling Process for Sheetings. Textile World Jl., vol. 55, no. 13, Mar. 29, 1919, pp. 29 and 31, 2 figs. Handling goods in finishing department; composition of mixings.

MECHANICS

Angles, Section Moduli

The Angle as a Beam, R. Fleming. Eng. News Rec., vol. 82, no. 9, Feb. 27, 1919, pp. 433-434, 5 figs. Tables comparing section moduli angles of various sizes.

Axles, Critical Velocity

Critical Velocity of High Speed Axles—II (La velocità critica degli alberi a grande velocità), Industria, vol. 33, no. 4, Feb. 28, 1919, pp. 113-114, 3 figs. On Dunkerley's theorem.

Beams

On the Beam of Uniform Strength, Taking the Weight of the Beam Into Consideration (in Japanese), Keiichi Aichi. Jl. Soc. Mech. Engrs., Tokyo, vol. 22, no. 54, Nov. 1918.

Bevel Gears, Strength of

Distribution of Load on Bevel Gear Teeth and Strength of Bevel Gear Teeth, W. G. Dunkley. Machinery, vol. 13, no. 337, Mar. 13, 1919, pp. 660-662, 4 figs. Investigation of variation of load in bevel-gear teeth; diagram illustrating deflection of teeth under load and graph showing distribution of load on teeth and their strength.

Gear Drives

Dynamics of Gear Drive, N. W. Akimoff. Jl. Am. Soc. Naval Engrs., vol. 31, no. 1, Feb. 1919, pp. 46-52, 1 fig. Designing formula.

MOTOR-CAR ENGINEERING

Carburetor Testing

Bureau of Standards Carburetor Test Plant, P. M. Heldt. Automotive Industries, vol. 40, no. 12, Mar. 20, 1919, pp. 641-644, 6 figs. Designed to determine metering qualities of different carburetors under varying conditions of atmospheric pressure and pressure drop. Fifth article.

System of Testing Fuel Jets in Zenith Carburetors. Aerial Age, vol. 9, no. 2, Mar. 24, 1919, p. 121, 4 figs. Machinery used in Zenith laboratory.

Carburetors

The Cox "Atmos" Carburetor. Autocar, vol. 42, no. 1221, Mar. 15, 1919, pp. 358-360, 7 figs. Results of tests of carburetor using only one jet and having no automatic moving parts.

Fiat

The New Fiat Light Car. Autocar, vol. 42, no. 1221, Mar. 15, 1919, pp. 355-357, 6 figs. Mechanical points in construction of engine, gear box and rear axle.

Fire Apparatus

Motor Apparatus and Equipment. Fire & Water Eng., vol. 65, no. 13, Mar. 26, 1919, pp. 649-653. Motor apparatus at Highland Park, Mich., equipped with Sewell cushion wheels.

French Cars

Automotor Design and Construction of 1919. Auto., vol. 24, no. 949, Mar. 13, 1919, pp. 250-252, 5 figs. Six-cyl. 23.9-hp. Delage type being exhibited at Lyons Fair.

A Standardized French Car. Autocar, vol. 42, no. 1221, Mar. 15, 1919, pp. 368-369, 6 figs. Details of 10-hp. 4-cyl. monobloc-engine car.

Headlights

Report of 1917-18 Committee on Automobile Headlighting Specifications. Trans. Illum. Eng. Soc., vol. 14, no. 2, Mar. 20, 1919, pp. 64-77 and (discussion) pp. 77-99, 2 figs. Specifications are based upon practical considerations and tests, and are selected in a manner to make them applicable to all devices.

Lubrication

Lubricating the Farm Tractor. Motor Age, vol. 35, no. 8, Feb. 20, 1919, pp. 28-29, 2 figs. Suggestion in regard to selection and application of lubricants.

The Lubrication of Motor Cars—II, G. W. A. Brown. Automotive Industries, vol. 40, no. 14, Apr. 3, 1919, pp. 751-754, 20 figs. Discussion of methods employed in lubrication of steering gears, drag links, rear axles, springs, spring eyes and road wheels; oil- and grease-retaining devices.

Mercury

The 10-12 hp. Mercury. Autocar, vol. 42, no. 1221, Mar. 15, 1919, pp. 583-584, 6 figs. Engine and transmission details.

Military Chassis

Military Transport Chassis—XII. Automobile Engr., vol. 9, no. 124, Mar. 1919, pp. 68-71, 5 figs. Performance under war conditions. Albion 32-hp. (3 tons) chassis.

Napier Trucks

A New Two-Tonner. Motor Traction, vol. 28, no. 733, Mar. 19, 1919, pp. 240-242, 6 figs. Designed for reliable and inexpensive operation. Napier 40-55 cwt. chassis.

Producer Gas for Tractors

Producer Gas Driven Tractors (Tracteurs à gaz pauvre). Bulletin de la Société d'Encouragement pour l'Industrie Nationale, vol. 131, no. 1, Jan.-Feb. 1919, pp. 185-187, 2 figs. Tests with Cages truck.

Talbot

A New 25-50 hp. Talbot. Autocar, vol. 42, no. 1221, Mar. 15, 1919, pp. 352-354, 3 figs. Main features are: Cylinders cast in pairs; pump water circulation; forced oil circulation; electric starting and lighting; cone clutch, with fabric on flywheel.

Tanks

The French Baby Renault Tank, W. F. Bradley. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, pp. 464-470, 12 figs. Weighs $6\frac{1}{2}$ tons with machine gun. Driving sprocket is at rear, endless band passes around pulley at front, and between these is a series of idlers and automatic tensioning apparatus.

Tractor Attachments

The Big Auto Tractor Attachment. Automotive Industries, vol. 40, no. 10, Mar. 6, 1919, pp. 528-529, 3 figs. Conversion unit for converting large touring cars of older models into farm tractors.

Tractors

An Analysis of Tractor Specifications, P. M. Heldt. Automotive Industries, vol. 40, no. 10, Mar. 6, 1919, pp. 522-524, 6 figs. Representation of different features of design on percentage basis. Charts based on count of American-built tractors.

The Austin Farm Tractor. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, p. 484. British tractor on Fordson lines.

Southern Tractor Requirements, B. M. Ikert. Motor Age, vol. 35, no. 13, Mar. 27, 1919, p. 27. Protection of working parts from dust and sand held to be of greatest importance.

Ball Bearings in Tractor Design, H. M. Trumbull. Can. Machy., vol. 21, no. 8, Feb. 20, 1919, pp. 179-183 and 187, 20 figs. Advocates using high-grade self-aligning ball bearing and illustrates its operation under various conditions of tractor service. From Tractor and Trailer.

Novel Frame in S. W. H. Tractor. Motor Age, vol. 35, no. 8, Feb. 20, 1919, pp. 46-47, 4 figs. Housing of gear set and rear axle in single casting.

Fiat Tractor Design Changes, W. F. Bradley. Automotive Industries, vol. 40, no. 10, Mar. 6, 1919, pp. 525-526, 4 figs. Secondary shaft behind axle housing; straight belt drive.

Vulcan

The Eight-Cylindered 20-25 H. P. Vulcan. Auto., vol. 24, no. 949, Mar. 13, 1919, pp. 247-250, 5 figs. Description and discussion with reference to characteristics of "eights" in general.

See also MECHANICAL ENGINEERING,

Internal Combustion Engines (Carburetion, High Speed Engines, Truck and Tractor Engines, Valves); RAILROAD ENGINEERING, Equipment (Motor Inspection, Cars).

PIPE

Corrosion

Health Board Studies Pipe Corrosion in Buildings. Eng. News Rec., vol. 82, no. 10, March 6, 1919, pp. 469-470, 6 figs. Examinations of sewer and vent-pipe systems in buildings of various ages found in the Chicago business district.

Couplings

Lead Pipe Couplings, John A. Jensen. Can. Engr., vol. 36, no. 1, Jan. 2, 1919, pp. 107-108. Results of examination of street leaks. Paper read before St. Louis Convention Am. Water Works Assn.

POWER GENERATION

Appalachian System

The Appalachian Power System, H. S. Slocum. Power, vol. 49, no. 12, Mar. 25, 1919, pp. 438-444, 12 figs. Features of hydroelectric and steam system supplying electric current to a large section of the South. Glen Lyn steam station.

Atlantic Seaboard

Power Supply for Atlantic Seaboard. Elec. World, vol. 73, no. 13, Mar. 29, 1919, pp. 638-639, 1 fig. Scope of plan of Secretary of Interior Lane for development of superpower stations in Boston-Washington district. Paper before Boston section Am. Inst. Elec. Engrs.

Australia

Water-Power Resources in Australia, Douglas Mawson. Commonwealth Engr., vol. 6, no. 6, Jan. 1, 1919, pp. 181-182. Figures gathered by writer show that a total of 13,722,000 hp. is available in Australasia; of this he believes 8,500,000 hp. is capable of development in Papua.

Hydroelectric Developments, Costs

General Factors Affecting the Cost of Constructing Hydro-Electric Development. Eng. & Contracting, vol. 51, no. 11, March 12, 1919, pp. 271-273. Investigation by Public Utilities Commission of State of Maine.

Massachusetts

Development of Massachusetts' Water Power. Elec. World, vol. 73, no. 6, Feb. 8, 1919, pp. 272-273, 1 fig. Special commission declares public ownership to be of doubtful value as a water-power policy.

Muscle Shoals

United States Nitrate Plant No. 2 at Muscle Shoals, Ala., Charles H. Bromley. Power, vol. 49, no. 12, Mar. 25, 1919, pp. 424-431, 8 figs. Data on flow and available power of Tennessee River at that point. Table of specifications of plant. First article of series.

Nationalization

Nationalization of Transport and Electricity Supply. Tramway & Ry. World, vol. 45, no. 13, Mar. 13, 1919, pp. 113-115. Scheme for unification and cheapening of communication.

Oil Engines

Place for Oil-Engine-Driven Generators. Elec. World, vol. 73, no. 11, March 15, 1919, pp. 519-520. Operating and maintenance expenses; analysis of expenses with old and new types of engines.

Solar Energy

The Utilization of Solar Energy, J. F. Heffron. Power House, vol. 12, no. 3, Mar. 1919, pp. 56-59, 5 figs. Review of attempts that have been made to utilize sun heat and indication as to what may be accomplished in future.

Sweden

The Extension of Hydro-Electric Power in Sweden. Engineering, vol. 107, no. 2775, Mar. 7, 1919, pp. 302-304. Calculations and investigations of Roy. Swedish Waterfalls Board.

Power Conditions in Europe. Power Plant Eng., vol. 23, no. 7, Apr. 1, 1919, pp. 332-334. Developments proposed in Sweden. Data supplied by Roy. Consulate of Sweden.

POWER PLANTS

Air Heaters for Boilers

Boilers Provided with Air Heaters (Les chaudières avec réchauffeurs d'air), J. R. Revue Générale de l'Electricité, vol. 5, no. 7, Feb. 15, 1919, pp. 265-269, 8 figs. Installation by Underfeed Stoker Co. in English plant. Heat contained in the chimney gases of boiler is utilized for heating air entering the furnace.

Ash Disposal

Fast Modern Methods of Ash Disposal. Black Diamond, vol. 62, no. 12, Mar. 22, 1919, pp. 332-335, 6 figs. Comparison of methods; review of book published by Am. Steam Conveyor Corp.

Central Heating Plant of the Colorado State College. Power, vol. 49, no. 10, March 11, 1919, pp. 346-348, 6 figs. Coal- and ash-handling equipment.

Power Plant Management; Coal and Ash Handling—I, Robert June. Power House, vol. 12, no. 3, Mar. 1919, pp. 60-62, 3 figs. Claims that elimination of hand labor is an important element in power-plant operation. Also in Refrig. World, vol. 54, no. 3, Mar. 1919, pp. 23-25, 3 figs.

Boiler Explosion

Boiler Explosion at Mobile. Power, vol. 49, no. 12, Mar. 25, 1919, pp. 432-436, 11 figs. Particulars of explosion of two Heine boilers at plant of Mobile Electric Co.

Boiler Interconnection

New Boiler Plant of the A. S. & R. Co. at Omaha, R. N. Robertson. Power, vol. 49, no. 14, Apr. 8, 1919, pp. 514-518, 7 figs. Main feature of this underfed stoker plant is interconnection of two boilers which are baffled to utilize radiant energy from fire; superheater is placed behind bridge wall.

Boiler-Tube Ruptures

Water-Tube Boiler Tube Ruptures, Weldon Melroy. Power, vol. 49, no. 9, March 4, 1919, pp. 302-303, 5 figs. Illustrations of ruptures from various causes.

CO_2 Recorders

Fuel Economy in the Boiler House—III, J. B. C. Kershaw. Chem. & Metallurgical Eng., vol. 20, no. 6, March 15, 1919, pp. 291-295, 8 figs. Description of German types of CO_2 recorders which depend on measurements of the physical properties of flue gas.

Coal Consumption

The Coal Consumption of Steam Power Plant, Robert H. Parsons. Elec. Rev., vol. 84, no. 2152, Feb. 21, 1919, pp. 200-202, 4 figs. Charts of coal consumption, steam consumption, coal efficiency and water efficiency.

Saving Coal in Steam Power Plants, Dept of Interior, Bur. of Mines, Technical Paper 217, 8 pp., 1 fig. Economical principles and method of applying them to power-plant operation.

Condensers

Installation and Operation of Condensers (Remarques sur l'établissement et l'exploitation des installations de condenseurs), C. Oettinger. Revue Générale de l'Electricité, vol. 5, no. 11, Mar. 15, 1919, pp. 419-422, 5 figs. Suggestions to engineer assuming direction of condensing apparatus in steel plant.

Economizers

Economizer Practice, M. E. Alone. Power Plant Eng., vol. 23, no. 7, Apr. 1, 1919, pp. 311-315, 2 figs. Saving, materials, cleaning, keeping track of performance, temperatures, gas volume, and air leakage in steam-boiler plants.

Equipment

Modern Steam Power Station Equipment, Joseph G. Worker. Blast Furnace & Steel Plant, vol. 7, no. 4, Apr. 1919, pp. 177-182, and 202, 13 figs. Review of modern steam power-plant equipment installed to meet demand of increased power facilities.

Exhaust Steam

Values of Exhaust Steam, R. L. Wales. Natl. Engr., vol. 23, no. 4, Apr. 1919, pp. 156-161, 5 figs. Discussion of factors to be considered when calculating relative values; distribution of costs between power and heat; charts for computation of comparative values.

Hand-Fired Plants

Saving Coal in Boiler Plants, Henry Kreisinger. Universal Engr., vol. 29, no. 2, Feb. 1919, pp. 45-54, 3 figs. Suggestions given to operators of hand-fired plants.

Power Costs

Saving Coal in Steam Plants, Edward J. Willis. Natl. Engr., vol. 23, no. 4, Apr. 1919, pp. 170-172. Data of costs of production.

Emergency Shop Power and Coal Conservation, C. E. Clewell. Am. Mach., vol. 50, no. 12, Mar. 20, 1919, pp. 533-536, 6 figs. Graph showing how operating costs per unit of energy delivered may vary for different values of percentage of use.

Calculation of Plant Efficiencies and Fuel Costs, J. T. Foster. Power, vol. 49, no. 9, March 4, 1919, pp. 316-318, 2 figs. Charts.

Power-House Economy

Getting Better Economy in the Power House, G. H. Kelsay. Elec. Ry. Jl., vol. 53, no. 10, Mar. 8, 1919, pp. 455-460, 9 figs. Relation of boiler load to efficiency; increase in efficiency of steam turbines and relation of coal used to available supply; curves showing progress of combustion beyond fuel bed and effect of excess air. Abstract of paper read before Central Elec. Ry. Assn.

Power Plants

Power Plants of New Gotham Hotels. Black Diamond, vol. 62, no. 12, Mar. 22, 1919, pp. 321 and 335, 4 figs. Battery of boilers of 15,000 hp.

Stokers

Erith-Riley Mechanical Stokers. Engineering, vol. 107, no. 2774, Feb. 28, 1919, pp. 268-269, 5 figs. Development of Erith-Riley stoker in conjunction with large boiler plants installed on the unit system.

Valves

Notes on the Repairing and Adjusting of Valves, W. H. Wakeman. Domestic Eng., vol. 86, no. 13, Mar. 29, 1919, pp. 556-559, 12 figs. Suggestions to steamfitters on repairing and adjusting valves of various types.

Water Softening

Water Softening, E. V. Chambers. Chem. News, vol. 118, no. 3066, Jan. 17, 1919, pp. 27-29. Treatment given in North of England to upland surface water intended for use in textile industry.

Water Softening, P. E. King. Chem. News, vol. 118, no. 3065, Jan. 10, 1919, pp. 14-16. Classification and description of methods.

See also MECHANICAL ENGINEERING, Handling of Materials (Ash Handling), Measurements and Measuring Apparatus; MARINE ENGINEERING, Auxiliary Machinery (Evaporators).

POWER TRANSMISSION

Belt Transmission

On the Power Transmission by Belt and Pulley (in Japanese), Chido Sugatani. Jl. Soc. Mech. Engrs., Tokyo, vol. 22, no. 54, Nov. 1918.

PRODUCER GAS

Operation

Gas Producers (Les gazogènes), G. Marconnet. Chimie & Industrie, vol. 2, no. 1, Jan. 1, 1919, pp. 6-14, 6 figs. Classification; operating data.

Theory

Elementary Theory of the Gas Producer, W. L. Badger. Mich. Technic, vol. 31, no. 1, Mar. 1918, pp. 13-17, 2 figs. Le Chatelier theorem.

REFRACTORIES

Graphite Ash Fusibility

Fusibility of Graphite Ash and Its Influence on the Refractoriness of Bond Clay, M. C. Booze. Jl. Am. Ceramic Soc., vol. 2, no. 1, Jan. 1919, pp. 65-68. From laboratory tests it is concluded that the softening point of a graphite ash is not a true criterion of its action in a crucible body.

Ovens and Kilns

Ovens and Kilns with a High Thermal Efficiency, A. Bigot. Gas Jl., vol. 145, no. 2905, Jan. 14, 1919, p. 71. Laboratory kiln with waste pipe surrounded by sheet-iron recuperator claimed by author to have increased by 200 deg. cent. temperature of interior of kiln. Paper before Ceramic Soc.

Research

Refractory Materials as a Field for Research, Edward W. Washburn. Jl. Am. Ceramic Soc., vol. 2, no. 1, Jan. 1919, pp. 3-31, 1 fig. Survey of scientific aspects of subject. Report drafted under auspices of Section of Indus. Research of Nat. Research Council.

REFRIGERATION

Cold Storage Abroad

Refrigeration Abroad. Ice & Refrigeration, vol. 56, no. 3, Mar. 1919, pp. 174-175. Cold storage accommodations in Great Britain, Australia, and Russia.

Compression Refrigerating Machine

The Compression Refrigerating Machine, Gardner T. Voorhees. Ice & Refrigeration, vol. 56, nos. 2 and 3, Feb. and Mar. 1919, pp. 99-100 and 149-151, 6 figs. Comparison of types; conditions of heat flow. (To be continued.)

The Ammonia Compression Refrigerating System XXXVIII, W. S. Doan. Refrig. World, vol. 54, no. 3, Mar. 1919, pp. 30-32, 4 figs. Atmospheric parallel flow type ammonia condenser; submerged condenser, shell type condenser; submerged and shell type condensers.

Fur Storage

Cold Storage of Furs, B. F. Green. Refrig. World, vol. 54, no. 3, Mar. 1919, pp. 25-26. Suggestions in regard to efficiency and safety.

Hotel Equipment

Refrigerating Equipment of the Pennsylvania Hotel. Power, vol. 49, no. 14, Apr. 8, 1919, pp. 522-524, 3 figs. Equipment has ice making capacity of 100 tons per day.

Refrigerating Plant Efficiency

Refrigerating Plant Efficiency, Victor J. Azbe. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 362-368, 10 figs. General discussion of refrigerating plant economics. Abstract of paper read at Annual Meeting of A.S.M.E., December 1918.

PUMPS

Centrifugal Pumps

On the Combined Running of Centrifugal Pumps (in Japanese), Iwao Oki. Jl. Soc. Mech. Engrs., Tokyo, vol. 22, no. 54, Nov. 1918.

RESEARCH

Canada

The Canadian Honorary Advisory Council for Scientific and Industrial Research, A. B. Macallum. Can. Min. Jl., vol. 45, no. 2, Jan. 15, 1919, pp. 28-29. Situation which has confronted Research Council since its erection in Dec. 1916.

Chemical Warfare Service

The Research Division, Chemical Warfare Service, U. S. A., George A. Burrell. Jl. Indus. & Eng. Chem., vol. 11, no. 2, Feb. 1, 1919, pp. 93-104. Review of work done by Service, beginning with its inception before U. S. entered war, and covering development of Division, including personnel, location of various parts of work and some of the problems attacked and solved.

England

The Government and the Organisation of Scientific Research, Frank Heath. Jl. Roy. Soc. Arts, vol. 67, no. 3457, Feb. 21, 1919, pp. 206-215 and (discussion) pp. 215-219. Difficulties encountered by Department of Sci. and Industrial Research, England.

The Organization of Research in Great Britain. Science, vol. 44, no. 1262, March 7, 1919, pp. 239-241. Abstract of report of Committee of Privy Counsel for Scientific and Industrial Research.

Industrial Laboratories

Technical Direction of an Industrial Laboratory (Direction d'un laboratoire industriel au point de vue analytique), Paul Nicolardot. Chimie & Industrie, vol. 2, no. 1, Jan. 1, 1919, pp. 18-24, 5 figs. Concerning standardization of methods of analysis and relations with other laboratories.

Rolling-Mill Research Laboratory

Rolling Mill Research Laboratory Founded. Blast Furnace & Steel Plant, vol. 7, no. 4, Apr. 1919, pp. 183-185, 2 figs. Experimental rolling mill and bureau of rolling mill research, organized in Pittsburgh by leading steel and rolling-mill manufacturers under auspices of Carnegie Inst. of Technology.

See also MECHANICAL ENGINEERING, Refractories (Research); AERONAUTICS, Research.

SPECIFICATIONS

Leather Belting

Specifications for Leather Belting, Harry A. Hey. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 275-281, 2 figs. Requirements to control quality from new point of view.

Steel, High-Speed

Specifications for High Speed Steels, R. Poliakoff. Iron Age, vol. 103, no. 13, Mar. 27, 1919, pp. 827-829. Questions to take into consideration in drafting specifications, with reference to European practice.

STANDARDS AND STANDARDIZATION

Brass and Bronze Foundries

Standards for Brass and Bronze Foundries and Metal Finishing Processes, William Erskine. Metal Indus., vol. 17, no. 3, March 1919, pp. 113-117. Methods and apparatus to protect health of workers.

Marine Engines

Standardization of Marine Engines. Mar. Rev., vol. 49, no. 4, Apr. 1919, pp. 179-182, 2 figs. Composite design embodying approved features of standard types is advocated.

Standards

Standards in Engineering, R. J. Durley. Jl. Eng. Inst. Can., vol. 2, no. 3, Mar. 1919, pp. 174-182. Their importance in limiting costs of manufacture and facilitating production. Notes on attention now being given in England and U. S. to standards.

STEAM ENGINEERING

Boilers

Talbot Boilers and Engines Made in Canada. Power House, vol. 12, no. 3, Mar. 1919, pp. 66-98, 5 figs. Description of contraflow boiler and uniflow engine.

Evaporation Charts

Chart for Finding the Factor of Evaporation, G. H. Sheasley. Power, vol. 49, no. 11, March 18, 1919, p. 406, 1 fig. Chart gives required factor of any given steam-boiler performance.

Rotary Engines

Avery's Rotary Steam Engine. Natl. Engr., vol. 23, no. 4, Apr. 1919, pp. 173-174, 2 figs. Construction details and performance.

Steam-Turbine History

Steam Turbine Progress Reviewed Historically. Steam, vol. 23, nos. 2 and 3, Feb. and Mar. 1919, pp. 33-41 and 63-69, 37 figs. Review of British patent-office records. Mar. 1919: Impulse blading and blade materials. Also in Railroad Herald, vol. 23, no. 3, Feb. 1919, pp. 63-65; Universal Engr., vol. 29, no. 2, Feb. 1919, pp. 34-44, 13 figs.

Steam Turbines

The Assembly and Adjustment of Steam Turbines, J. Humphrey. Machinery, vol. 13, no. 331, Jan. 30, 1919, pp. 486-492, 14 figs. Turbines considered are those working on the Parsons principle and having large number of fixed and moving blades, calked into the casing and on the periphery of the rotor.

The Large Steam Turbine, J. F. Johnson. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 355-361, 7 figs. Development of large units to meet modern power requirements; records of performance; notes on design and construction.

WELDING

Arc-Welding Regulations

Notes on Regulations for Arc Welding, H. M. Sayers. Can. Machy., vol. 21, no. 2, Jan. 9, 1919, pp. 39-41. Precautions to be observed for safety of operator; effects of welding load on supply mains of power station.

Blowpipe, Oxy-Acetylene

How to Choose an Oxy-Acetylene Blowpipe, C. Royer. Can. Machy., vol. 21, no. 8, Feb. 20, 1919, pp. 184-187, 1 fig. Writer considers that determining factors are character of work to be done and equipment on hand, and refers to features he estimates as of paramount importance in various classes of service.

Frog Shop

Welding in the Frog Shop, B. K. Smith. Welding Engr., vol. 4, no. 3, Mar. 1919, pp. 19-20. Reclaiming of materials.

Lead Welding

The Autogenous Welding of Lead—II, P. Rosemberg. Acetylene & Welding Jl., vol. 15, no. 178, July 1918, pp. 118-119, 6 figs. Uses of hydrogen and air blowpipe.

Rail Joints

Modern Welding and Cutting, Ethan Viall. Am. Mach., vol. 50, no. 12, Mar. 20, 1919, pp. 529-532, 11 figs. Notes on welding various types of rail joints. Sixth article.

Seam Welding, Electric

Electric Seam Welding, P. T. Van Bibber. Am. Mach., vol. 50, no. 13, Mar. 27, 1919, pp. 575-580, 14 figs. Details of welding roller head; lap-seam welding machine and Thomson machine for flange-seam welding.

Thermit Welding

Modern Welding and Cutting, Ethan Viall. Am. Mach., vol. 50, no. 11, Mar. 13, 1919, pp. 479-483, 11 figs. Thermit rail welding for electric systems. (Continuation of serial.)

Miscellaneous Thermit Repairs in the Nashville, Chattanooga & St. Louis Shops, Albert L. Seals. Reactions, First Quarter, 1919, pp. 18-20, 7 figs. Splice welded to main frame of engine; repair on a two-throw crankshaft.

Tires, Welded

Microscopic Study of Welded Tires. Acetylene & Welding Jl., vol. 16, no. 185, Feb. 1919, pp. 30-32, 30 figs. Structure of test pieces 3/16-in. from fracture, and tabulation of their characteristic differences according to position relative to fracture. (Concluded.)

Tool-Steel and Stellite Welding

Electric Welding of High-Speed Steel and Stellite in Tool Manufacture, P. T. Van Bibber. Am. Mach., vol. 50, no. 10, March 6, 1919, pp. 425-437, 80 figs. Stellite used only for vital parts is welded to shank of ordinary steel by butt-welding process. Operations, data and specifications.

WOOD

Applications

The Uses of Wood, Hu Maxwell. Am. Forestry, vol. 25, no. 303, Mar. 1919, pp. 923-930, 18 figs. Fencing materials from forests. Eleventh article.

Drying

English Methods of Lumber Drying, John Young. Wood-Worker, vol. 38, no. 1, Mar. 1919, p. 34, 1 fig. Details of English drykiln.

Seasoning

The Seasoning of Lumber, Bror L. Grondall, Sci. Am. Supp., vol. 87, no. 2253, Mar. 8, 1919, pp. 158-160. Basic facts underlying artificial drying of forest products. From West Coast Lumberman.

VARIA

Drawings, Reproduction of

Reproducing Drawings, F. G. Allen. Univ. Colo. Jl. Eng., vol. 15, no. 2, Jan. 1919, pp. 36-51. Discussion of the various methods of making duplicates of engineering drawings. Photo-chemical methods, lithographic methods, zinc etching, and half-tones, are considered.

Engineers

The Functions of the Engineer: His Education and Training, W. A. J. O'Meara. Elec. Rev., vol. 84, no. 2152, Feb. 21, 1919, pp. 219-221, 1 fig. Diagram of salaries and estimated personal qualifications.

Invention

Efficient Invention, Douglas Leechman. Automobile Engr., vol. 9, no. 124, Mar. 1919, pp. 74-79. Writer suggests that if present patent fees were suitably reduced, trade of country would be benefited by increased encouragement of invention. Particular reference to patents affected by the war. Paper presented to Instn. Automobile Engrs.

Licensing Engineers

Comparison of Various Existing and Proposed License Laws, Eng. News Rec., vol. 82, no. 9, Feb. 27, 1919, pp. 423-430. States that have laws regulating practice of engineering and those which contemplate establishing such laws.

Nomography

Nomography, M. J. Eichhorn. Natl. Engr., vol. 23, no. 4, Apr. 1919, pp. 165-169, 13 figs. Reduction tables for pressures, temperatures, etc., and graphical steam tables. (Continuation of serial.)

Semi-Logarithmic Paper

The Use of Semi-Logarithmic Paper in the Determination of Empirical Formulas, E. W. Lane. Cornell Civ. Engr., vol. 27, no. 1, Feb. 1919, pp. 3-8, 3 figs. Types of semi-logarithmic curves.

Steam-Distribution Charts

Chart of Steam Distribution (Abaque général pour l'étude des distributions de vapeur), Rodolphe Soreau. Mémoires et Compte rendu des Travaux de la Société des Ingenieurs Civils de France, vol. 71, nos. 11-12, Nov.-Dec. 1918, pp. 551-556, 2 figs. Chart is prepared to indicate any of three quantities, relative piston displacement, ratio of crank to connecting rod, and angle between crank and line of dead centers—when the other two are determined.

Organization and Management

ACCOUNTING

Cost Accounting

Uniform Cost Accounting. Ice & Refrigeration, vol. 56, no. 2, Feb. 1919, pp. 101-109, 8 figs. Forms covering cost accounting for production and distribution of ice, worked out by special committee of Nat. Assn. Ice Industries.

Cost Accounting to Aid Production—VII, G. Charter Harrison. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 314-318, 3 figs.

Expansion of application of scientific management principles. Theory illustrated by example of firm entering field of manufacturing automobile trucks.

Inventories .

Accurate Inventories Aid Output, Clifford E. Lynn. Iron Trade Rev., vol. 64, no. 13, Mar. 27, 1919, pp. 828-829, 2 figs. Form of keeping complete plant records of finished and semi-finished stocks.

Production Accounts

Systematizing Production Accounts, Ralph E. Butz. Iron Trade Rev., vol. 64, no. 12, Mar. 20, 1919, pp. 757-759. Methods for keeping records of costs in manufacturing plants. It is recommended that accounting be operated on double-entry principle.

EDUCATION

Crew Instruction at Hydroelectric Plant

Operation at Holtwood, Charles H. Bromley. Power, vol. 49, no. 12, Mar. 25, 1919, pp. 450-454, 6 figs. Methods used in instruction of crew at hydroelectric station of Pa. Water & Power Co. First article of series.

Education and Industry

Industry, Democracy, and Education, C. V. Corless. Bul. Am. Inst. Min. & Metallurgical Engrs., no. 148, Apr. 1919, pp. 621-635. Social problems developed from moral forces which found themselves released at termination of war.

Soldiers

Soldiers Civil Re-Establishment, L. Anthes. Jl. Eng. Inst. Can., vol. 2, no. 3, Mar. 1919, pp. 185-187. Notes on responsibility for soldiers' welfare placed on those who did not share their sacrifice.

Women, Training School for

Training Women in an Airplane Plant, James W. Russell. Machy., vol. 25, no. 7, Mar. 1919, pp. 593-595, 7 figs. Experiments and results in Curtiss Aeroplane & Motor Corporation's training school.

See also MINING ENGINEERING, Coal and Coke (Training of Students).

FACTORY MANAGEMENT

Credit

Mathematics of Credit Extension, Frederick Thulin. Jl. Accountancy, vol. 27, no. 4, Apr. 1919, pp. 259-267. Question of determining point of limitation to which grant of credit can go and of determining prima facie amount of capital, if any, a business requires from its proprietorship in reference to particular request of credit under consideration.

Employment System

Employment System of Cincinnati Planer Co., A. J. Schneider. Machy., vol. 25, no. 7, Mar. 1919, pp. 622-623, 8 figs. Forms of inquiry cards, record sheets and employment pass.

The Employment Department, G. L. Hostetter. Eng. & Indus. Management, vol. 1, no. 5, Mar. 13, 1919, pp. 142-143. Discusses effect of defective organization upon minds of applicants for employment and shows how first impressions generally influence the worker in the factory.

Selecting and Training Interviewers, Roy Willmarth Kelly. Indust. Management, vol. 57, no. 4, Apr. 1919, pp. 263-270, 9 figs. Analyzes knowledge and training needed by employment interviewer and points out specific information he should secure in regard to his community.

Forge-Shop Maintenance Department

Methods of Increasing Shop Efficiency, J. D. Lannon. Am. Drop Forger, vol. 5, no. 3. Mar. 1919, pp. 117-120. Schemes for sustaining maintenance department in forge shop. First article.

Human Activities, Classification of

Human Parasitism or Service, Harrington Emerson. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 257-262, 1 fig. Classifies human activities into nine elements. Graphs for purpose of aiding each one to know where he belongs and what he is doing.

Human Factor in Efficiency

The Human Factor in Efficiency Methods, C. A. Pells. Elec. Rev., vol. 84, no. 2153, Feb. 28, 1919, p. 228. Social, economic, and hygienic conditions of worker as affecting efficiency.

Industrial Organization

Managing for Maximum Production—II, L. V. Estes. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 284-288, 5 figs. Theory of functions of industrial organizations. It is advanced that the industrial machine should be so built that routine work becomes compulsorily automatic.

Problems of Industrial Organization, Major Greenwood. Colliery Guardian, vol. 117, no. 3035, Feb. 28, 1919, p. 477. Remarks that while details of production, quantities of goods made, nature and powers of machines are matters which can be adequately described, such is not the case with efficiency of workers. Paper before Roy. Statistical Soc. Also abstracted in Eng. & Indus. Management, vol. 1, no. 5, Mar. 12, 1919, pp. 150-154.

Labor Turnover

Proper Systems Reduce Labor Turnover. Automotive Industries, vol. 40, no. 12, Mar. 20, 1919, pp. 619-621. Statistics of labor turnover and analysis of factory methods for handling it.

Labor Turnover and a Remedy, W. H. Weingar. Am. Mach., vol. 50, no. 11, Mar. 13, 1919, pp. 497-499, 5 figs. How a munition plant has handled problem.

Layout of Works

The Thornycroft Motor Works at Basingstoke. Ry. Gaz., vol. 30, no. 5, Jan. 31, 1919, pp. 168-169, 5 figs. Layout of works and views of laboratories.

The Automobile Factory—III. Automobile Engr., vol. 9, no. 124, Mar. 1919, pp. 87-94, 18 figs. Notes on layout, construction and equipment.

Library

The Organization of a Factory Library, W. Barbour. Jl. Soc. Chem. Indus., vol. 39, no. 3, Feb. 15, 1919, pp. 35R-40R. Particulars of a system of indexing books, extracts, periodicals, manuscripts, papers, reports and charts.

Limitation of Output

The Limitation of Output, Andrew Stewart. Engineering Review, vol. 32, no. 9, Mar. 15, 1919, pp. 247-250, 6 figs. Deals with problem of restriction of output of men and machines.

Machine-Tool Plant

Organization and Management of a Machine Tool Plant, Oskar Kylin and Erik Oberg. Machy., vol. 25, no. 7, Mar. 1919, pp. 608-614, 10 figs. Principles of organization and details of system used in a medium-size machine-tool manufacturing plant. First article.

Management Systems

Democracy Applied to Shop Management. Iron Age, vol. 103, no. 12, Mar. 20, 1919, pp. 743-745. Describes system adopted by Am. Multigraph Co., said to be based on American form of government.

"Efficiology," a Method of Making Profits by Universal Democracy, W. S. Rogers and Nellie M. Scott. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 299-301, 3 figs. Method of Bantam Ball Bearing Co. Charts of authority and responsibility.

Milling Calculations

Milling Calculations, Robert S. Lewis. Chem. & Metallurgical Eng., vol. 20, no. 5, March 1, 1919, pp. 224-233, 2 figs. Formulae for determining extraction of processes, efficiency of machines, density of solids, solutions and pulps; notes on methods of testing and microscopic examination; bibliography of articles dealing with calculations.

Profit Sharing

A Profit-Sharing Plan for Executives, A. P. Ball. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 296-298, 3 figs. Experiment of Square D Company.

Rotation in Jobs

What Is the Value of Rotation in Jobs? Harry Tipper. Automotive Industries, vol. 40, no. 12, Mar. 20, 1919, pp. 628-629. Discussion whether employer or employee benefits most from shifting workers frequently.

Scientific Management

Seven Common Questions Regarding Scientific Management, Carle M. Bigelow. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 281-283. Objections that must be overcome in minds of business executives before they will consider the possibility of installing scientific management in their plants.

How I Have Applied the Taylor System (Comment j'ai mis en pratique le systéme Taylor), Serge Heryngfel. Mémoires et Compte rendu des Travaux de la Société des Ingénieurs Civils de France, vol. 71, nos. 11-12, Nov.-Dec. 1918, pp. 557-559, 17 figs. Personal experiences in organization work.

Science and Industry (La science et l'industrie). Métallurgie, vol. 51, nos. 1 and 2, Jan. 1 and 8, 1919, pp. 26 and 75. Conducting industrial operations by scientific methods of organization.

Guiding the Creative Instinct, W. R. Basset. Factory, vol. 22, no. 3, March 1919, pp. 449-452. Concerning scientific management and the psychological characteristics of workers.

Shop Routing

Shop Routing System Reduces Handling Costs, F. L. Prentiss. Iron Age, vol. 103, no. 14, Apr. 3, 1919, pp. 867-870, 5 figs. Methods of Cleveland Tractor Co.

Store Room

Distribution of Materials and Supplies, B. J. Yungbluth. Elec. Ry. Jl., vol. 53, no. 10, Mar. 8, 1919, pp. 473-475. Economic aspect of methods followed in storeroom.

Keeping Track of Factory Material, J. C. Hickman. Factory, vol. 22, no. 3, March 1919, pp. 465-469, 16 figs. Remarks on specifying, receiving and inspecting purchase. First article.

Time Study

Six Fundamentals of Time Study, Samuel R. Gerber. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 308-311. How they must be handled by time-study man.

Tool Room

Modern Tool Room Organization. Machinery, vol. 13, no. 331, Jan. 30, 1919, pp. 477-479, 7 figs. Scheme of the record and costing of jigs and fixtures.

Trucks, Industrial

Conserving Labor in the Mill. Am. Miller, vol. 47, no. 4, Apr. 1, 1919, pp. 319-320, 4 figs. Suggests cutting down overhead by employing industrial truck to do work of many men.

Timken Solving Difficult Production Problem, Edward Schipper. Automotive Industries, vol. 40, nos. 13 and 14, Mar. 27 and Apr. 3, 1919, pp. 685-688 and 748-750, 13 figs. Mar. 27: Methods for scheduling work of Timken-Detroit Axle Co. Apr. 3: Practice of company in departmental communication, by using electric trucks.

Welfare

Welfare in the Factory. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, p. 77. Influence of the State.

FINANCE AND COST

Prices

Civil War Price Trends Compared with Those Today, Morris Knowles. Eng. News-Rec., vol. 82, no. 9, Feb. 27, 1919, pp. 414-416, 2 figs. Writer, judging by past, believes high prices will continue.

LABOR

American Conditions

American Workmen During the War (Le travail américain pendant la guerre). Revue Générale de l'Electricité, vol. 5, no. 7, Feb. 15, 1919, pp. 275-278. Survey of organization work in United States, specially of relations between workers and employers.

Crippled Soldiers

Economic Benefit to Mining Industry Illustrated by Experience with Crippled Soldiers, Douglas C. McMurtrie. Colo. School Mines Mag., vol. 9, no. 3, Mar. 1919, pp. 55-57. Studies of Red Cross Inst. for Crippled and Disabled Men.

Dilution of Labour

Dilution of Labour. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, p. 76. Progress and consequences; methods of training.

Housing

Attractive Homes for Employees, W. F. Sutherland. Can. Machy., vol. 21, no. 10, Mar. 6, 1919, pp. 234-237, 17 figs. Plan of housing development at Chippewa plant of Norton Co.

Westinghouse Village at South Philadelphia, Pa. Am. Architect, vol. 115, no. 2251, Feb. 12, 1919, pp. 223-229, 10 figs. Tract set aside for housing contains about 90 acres.

Town Housing of the Working Classes, Herbert Freyberg. Surveyor, vol. 55, no. 1409, Jan. 17, 1919, pp. 31-32. Experience of administration of part III of act of 1890. Before Soc. Architects.

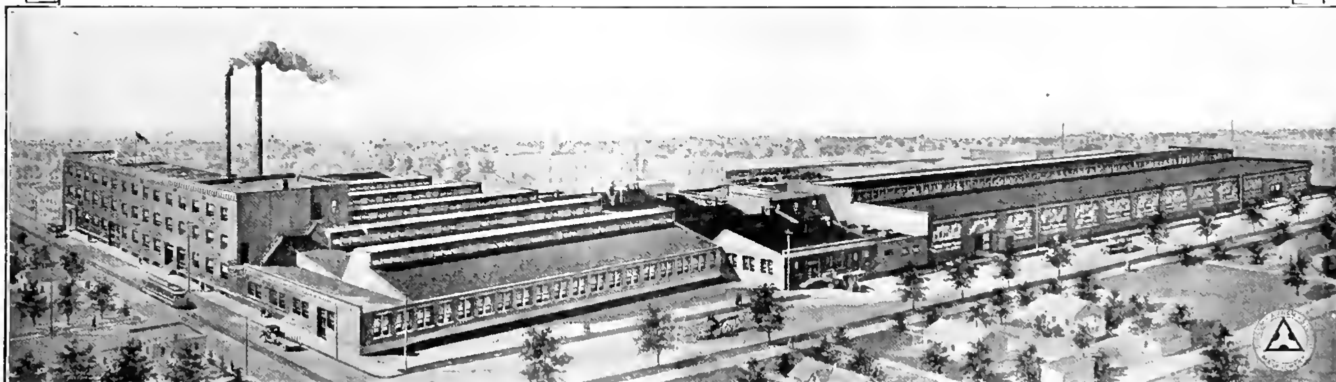
Housing from the Point of View of Economy in Planning and Construction, Henry Tanner. Jl. Roy. Sanitary Inst., vol. 39, no.

Let Us Do Your Special Work

Production Work and Special Work as you want it—and when you need it

When you give Production Work or Special Work to the S. A. S. Laboratories you can feel certain to get accuracy and fine work—the kind you have hoped for, but never expected to get. All work is done by experts, each a specialist in his line. We have more than 500 men trained to do things right and do them well—trained to produce accurate and fine work in large quantities—trained to make the last hundred as good as the sample submitted.

No organization is better equipped to handle your work, and most not as well—we were the only successful manufacturer of Schneider Sights, used on 155m and 240m Howitzers, for the United States Government as well as other extremely accurate devices.



SLOCUM, AVRAM & SLOCUM LABORATORIES, INC.
NEWARK, N. J.

A complete service is offered—

To work with you and for you—from designing to finishing—whether you need a simple part of accurate measurement or an intricate mechanical device that must work accurately—we can do it and do it right—and deliver on time.

What the S. A. S. Laboratories can and will do for you:

—cooperate with you
—design and perfect your special parts or complete machines
—build and perfect working models
—relieve you of troublesome work and make it profitable for you
—handle your production work in any quantity with speed and accuracy

This is the second of a series of advertisements showing our plant, our methods and the work we are doing. Watch for them.

Investigate today—learn just wherein our services are invaluable to you.

LET US BUILD YOUR SPECIAL MACHINES

SLOCUM, AVRAM & SLOCUM LABORATORIES, Inc.

Factory
NEWARK, N. J.

New York Office
30 PINE ST., N.Y.

IT WILL BE RIGHT IF WE BUILD IT

2, Oct. 1918, pp. 79-84. British Government view as to what is proper accommodation to be provided for workers.

The Cost and Construction of Workmen's Dwellings, Roads, Sewers, and Water Supply in Connection with Town Planning. John Parker. Jl. Roy. Sanitary Inst., vol. 39, no. 2, Oct. 1918, pp. 75-78. Conditions and legal regulations at Hereford.

Industrial Councils, Joint

Whitley Plan for Improving Labor Status. Contract Rec., vol. 33, no. 13, Mar. 26, 1919, pp. 279-280. Joint standing industrial councils recommended to provide remedy for differences between employers and employees.

The League of Labor and Capital. C. S. Robinson. Iron Age, vol. 103, no. 11, Mar. 13, 1919, pp. 683-684. Concerning coöperation in industry between employer and employee by establishing a basis for representation of workers.

Labor Representation

Labor's Representation in Plant Management the Immediate Problem. Harry Tipper. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, pp. 476-477, 2 figs. Chart illustrating representation of employees of Bethlehem Steel Corp. and subsidiary companies.

Profit Sharing

The Profit Sharing Plan of the Baker Manufacturing Co., John S. Baker. Wisconsin Engr., vol. 23, no. 6, Mar. 1919, pp. 193-201. Writer advocates plan for increased remuneration of employees with increased production, and illustrates instance of application of plan.

Psychology of Workers

The Human Machine. Arthur P. Young. Eng. & Indus. Management, vol. 1, no. 5, Mar. 13, 1919, pp. 135-137, 2 figs. Study of psychology of workers.

Unemployment

View of Unemployment from Employer's Side. Iron Age, vol. 103, no. 12, Mar. 20, 1919, pp. 747-748. Opinion of representatives of National Associations connected with metal trades.

Wage Problem

The Wage Problem in Industry. W. L. Hichens. Colliery Guardian, vol. 117, no. 3036, Mar. 7, 1919, p. 536. Suggests ways in which increase of wages may be effective in increasing production. Paper before Roy. Soc. Arts. See also Engineer, vol. 127, no. 3297, Mar. 7, 1919, pp. 231-232, and Jl. Roy. Soc. Arts, vol. 67, no. 3458, Feb. 28, 1919, pp. 224-229 and (discussion) pp. 229-233.

Probable Wages and Supply of Construction Labor During Coming Season. Eng. & Contracting, vol. 51, no. 12, Mar. 19, 1919, pp. 284-286. Committee report of Am. Road Builders' Assn.

Wage Systems (Les différents systèmes de salaires). Métallurgie, vol. 51, no. 11, Mar. 12, 1919, p. 587. Review of systems which have been put into practice in France, America, England and Germany. (To be continued.)

Problems and Formulæ for Payment of Wages (Problèmes et formules de paiement des salaires). Technique Moderne, vol. 10, no. 12, Dec. 1918, pp. 571-574, 1 fig. Includes graph for the Benedict-Stronck, Emerson, Halsey, Rowen, Taylor and Gantt systems. From Metallurgical and Chemical Eng., Mar. 1, 1918; Annales des Ponts et Chaussées, Apr.-May 1917 and previous account in Technique Moderne, vol. 10, no. 1, Jan. 1918, p. 17.

Different Wage Systems (Les différents systèmes de salaires). Métallurgie no. 12, Mar 19, 1919, pp. 649-650, 5 figs. Different wage systems; relation of wage system to effective production. (Continuation of serial.)

Women

Women in the Industry. George H. Priest. Gas Indus., vol. 19, no. 3, Mar. 1919, pp. 73-75. Results from questionnaire sent out to 28 gas works.

LEGAL

Boiler Legislation, Low-Pressure

Low Pressure Boiler Legislation. Official Bul. Heating & Piping Contractors Nat. Assn., vol. 26, no. 3, Mar. 1919, pp. 26-28. Quotes a number of bills now pending before legislatures of several states.

Building Contracts

The Building Contract of the Future. Sullivan W. Jones. Jl. Am. Inst. Architects, vol. 7, no. 3, Mar. 1919, pp. 119-122. Analysis of various forms of existing contracts and suggested changes in policy on building loans. From address before Inst. Elec. Contractors.

Disability

Disability Under the Compensation Acts I, II, III. Chesla C. Sherlock. Am. Mach., vol. 50, nos. 10, 11 and 13, Mar. 6, 13 and 27, 1919, pp. 415-418, 499-502 and 597-599. Court decisions in cases involving temporary disability.

See also MECHANICAL ENGINEERING, Heating and Ventilation (Laws).

LIGHTING

Gas Lighting

Modern Gas Lighting. Philmer Eves. Gas Indus., vol. 19, no. 3, Mar. 1919, pp. 70-72. Practice in churches, public buildings, etc.

Illumination Intensity

Industrial Illumination. Geo. K. McDougall. Jl. Eng. Inst. Can., vol. 2, no. 3, Mar. 1919, pp. 210-215, 8 figs. Review of general information on subject and data of foot candle intensity for various classes of work.

Lighting and Production

Four Conclusive Tests of Production Value of Good Factory Lighting. Elec. Rev., vol. 74, no. 12, Mar. 21, 1919, pp. 449-451, 4 figs. Details of tests conducted by Testing Department of Commonwealth Edison Company. Average increase of production ranges from 10 to 20 per cent.

RECONSTRUCTION AND EXPORT TRADE

Belgium

Reconstruction in Belgium. Times Eng. Supp., vol 15, no. 532, Feb. 1919, p. 69. Requirements in tools; disorganization of transport; problem of labor.

Coal Trade

American Opportunities in the Foreign Coal Trade. Coal Age, vol. 15, no. 11, March 13, 1919, pp. 486-488. From Colliery Guardian.

Electrical Goods

Electrical Competition in Foreign Markets. Joseph M. Goldstein. Elec. World, vol. 73, no. 10, Mar. 8, 1919, pp. 468-471, 2 figs. How the industry in the United States may compete with Allgemeine Elektrizitaets-Gesellschaft of Berlin, which, it is asserted, has dominated the world.

Electrical Goods in Japan. Jl. Electricity, vol. 42, no. 6, Mar. 15, 1919, pp. 266-267. Possibilities of American trade.

Financial Aspect of Reconstruction

The Problem of Reconstruction. Southwestern Elecn., vol. 14, no. 11, Jan. 1919, pp. 14-16. Financial aspect of problem.

France

The Problem of Rebuilding the Devastated Regions of France, Jean-Paul Alaux. Jl. Am. Inst. Architects, vol. 7, no. 3, Mar. 1919, pp. 115-117. Visualization of extent of reconstruction work to be required.

Great Britain

Reconstruction in Great Britain Following the War, H. Babington Smith. Sci. Monthly, vol. 8, no. 4, Apr. 1919, pp. 298-305. Problems of demobilization, vocational instruction of soldiers, and disposal of property in reserve for military purposes.

Latin America

Some Agencies in the Development of Closer Relations with the Countries of Central and South America. L. S. Rowe. Sci. Monthly, vol. 8, no. 4, Apr. 1919, pp. 320-322. Effectiveness of international organization based on moral and cultural ties between nations.

Market for Electrical Goods in South America—II. Philip S. Smith. Elec. World, vol. 73, no. 10, Mar. 8, 1919, pp. 479-481. Notes on Bolivia, Ecuador and British Guiana; résumé of South American conditions as a whole; list of central stations in Chile, Uruguay, Ecuador and Peru.

New Engineering Industries (England)

New Engineering Industries. Chem. News, vol. 118, no. 3070, Feb. 14, 1919, pp. 80-81. Report of Committee of Ministry of Reconstruction, appointed to compile list of articles (suitable for manufacture by those with engineering trade experience) not made in United Kingdom before war.

Railway Buying

Railway Buying and Industrial Readjustment, E. B. Leigh. Ry. Age, vol 64, no. 14, Apr. 4, 1919, pp. 879-881, 1 fig. Shows relation of railway purchases to general business conditions. Address delivered before Natl. Indus. Conference Board.

Union of International Associations

International Associations and After-War Constructions (Les associations internationales et la reconstitution de l'après-guerre), Paul Otlet. Revue Générale des Sciences, no. 4, Feb. 28, 1919, pp. 114-119. Work done by the Union of International Associations organized in 1910. Probable future relations of the Union with Science and Industry.

SAFETY ENGINEERING

Accident Prevention

The Limits of Accident Prevention. Eng. & Indus. Management, vol. 1, no. 5, Mar. 13, 1919, pp. 139-141, 3 figs. Study of accident causes in iron and steel industry based on statistical reports.

The Economics of Safety. Lew R. Palmer. Sci. Monthly, vol. 8, no. 4, Apr. 1919, pp. 350-355, 2 figs. Plant management in relation to accident prevention. As illustration organization of Safety Dept., U. S. Steel Corp., is quoted.

Elevator Accidents

Elevator Accidents and Their Causes. William J. Picard. Safety Eng., vol. 37, no. 3, Mar. 1919, pp. 117-123, 8 figs. Statistical charts and data.

Increasing Cage Safety. Thomas Price. Coal Age, vol. 15, no. 13, Mar. 27, 1919, p. 570, 2 figs. Scheme for attaching two ropes to each cage, either one of which is capable of sustaining load.

Fire Doors and Shutters

Covering Fire Doors and Shutters—I. Metal Worker, vol. 91, no. 13, Mar. 28, 1919, pp. 395-397 and 399, 16 figs. Information on size of sheets to use, method of notching and bending locks, etc., in conformance with underwriters' regulations.

Statistics of Accidents

Statistics in Accident Prevention. Evelyn M. Davis. Elec. World, vol. 73, no. 10, Mar. 8, 1919, pp. 476-477, 1 fig. Analysis of 1172 cases during two-year period, giving data on days lost and division of cost.

Industrial Accidents in the United States Iron and Steel Industry. Engineering, vol. 107, no. 2771, Feb. 7, 1919, pp. 164-167, 7 figs. Statistics giving frequency and severity of accidents.

See also MINING ENGINEERING, Coal and Coke (Fatalities), Mines and Mining (Accidents).

SALVAGE

Motor Shells

Saving Motor Shells from the Scrap Heap by Welding. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 581-586, 15 figs. Different steps in thermit method of welding motor shells as used by large electric-railway system; suggestions for relining crucibles and keeping welding tools in proper repair.

Tool-Steel Scrap

Reclaiming High-Speed Steel Scrap. Edwin F. Cone. Iron Age, vol. 103, no. 13, Mar. 27, 1919, pp. 805-808, 6 figs. Detection and sorting of steel scrap from nature of sparks from special grinding wheel.

War Material

Salvage of War Material. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, p. 70. Organization and research.

Waste of Industrial Materials

Common Wastes of Industrial Materials. H. E. Howe. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 303-307. Suggestions in regard to elimination of waste.

TRANSPORTATION

Crating

Crating Automobiles for Export. J. H. Teagan. Automotive Industries, vol. 40, no. 11, Mar. 13, 1919, pp. 570-571, 4 figs. Combining security with minimum waste of space.

Light as Aid to Transportation

Light as an Aid to the Transportation of Material. A. L. Powell and R. E. Harrington. Tran. Illum. Eng. Soc., vol. 14, no. 1, Feb. 10, 1919, pp. 1-17 and (discussion) pp. 17-23. Argues that proper lighting of stations, warehouses and piers increases their capacity which depends on speed with which material moves through them.

Mine Cars

Standardized Wagon Designs. J. R. Bazin. Colliery Guardian, vol. 117, no. 3037, Mar. 14, 1919, p. 595. Buffing and drawgear; wheels and axles; axle guards; brakes; body work. Paper read before Inst. Locomotive Engrs.

Rural Transport

Rural Transport. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, pp. 67-68. Suggestions being put forward to effect improvement.

Shop Haulage

Shop Haulage System of New Design. Iron Trade Rev., vol. 64, no. 12, Mar. 20, 1919, pp. 760-763, 13 figs. Geometric principle employed to enable cars to trail correctly and turn sharp corners without tracks; hauling unit is tractor capable of pulling 15 trucks.

Industrial Electric Tractors (Chariots transporteurs electriques pour manutention), Jacques Deschamps. Revue Générale de l'Electricité, vol. 5, no. 5, Feb. 1, 1919, pp. 171-174, 6 figs. Describes various types and their uses, also the Edison accumulator with which industrial tractors are usually operated.

Truck Transportation

Concrete Material for Army Base Hauled by Motor Trucks. Eng. News Rec., vol. 82, no. 8, Feb. 20, 1919, pp. 366-368, 4 figs. Analysis of truck performance and delivery cost. Equipment considered was utilized for stevedoring and haulage at South Brooklyn supply unit.

Economical Motor Transport. Iron Age, vol. 103, no. 11, Mar. 13, 1919, pp. 693-694, 1 fig. Experience in operation by large organization employing trucks in freight haulage.

Zoning

Industrial Zoning, Herbert S. Swan. Am. Architect, vol. 115, no. 2258, Apr. 2, 1919, pp. 500-503. Considers method of formulating zoning ordinance and of laying out several business and factory districts, in order to remove congestion in transportation.

Electrical Engineering

ELECTROCHEMISTRY

Electrolytes

The Effect of Some Simple Electrolytes on the Temperature of Maximum Density of Water, Robert Wright. Jl. Chem. Soc., vols. 115 and 116, no. 676, Feb. 1919, pp. 119-126, 1 fig. Reported from experiments that lowering of temperature produced by highly ionized binary electrolyte is composed of two separate, independent effects, one due to acid radical and other to basic radical of electrolyte.

Electrolytic Dissociation, S. Arrhenius. Chem. News, vol. 118, no. 3069, Feb. 7, 1919, pp. 61-64. Discussion of analytical-chemistry explanation of dissociation.

Electrolytic Conductivity in Non-Aqueous Solutions, Henry Jermain Maude Creighton. Jl. Franklin Inst., vol. 187, no. 3, March 1919, pp. 313-318. Results of measurements in 13 solvents are discussed with reference to viscosity, degree of association and dielectric constant of solvent.

Electroplating

Electro-Plating on Iron from Copper Sulphate Solution, Oliver P. Watts. Gen. Meeting Am. Electrochem. Soc., Apr. 3-5, 1919, paper 7, pp. 61-69. Arsenic, antimony, bismuth, lead and tin dipping solutions were tried. Arsenic, lead and antimony solutions said to be effective in securing a good subsequent electroplating of copper. Bismuth was electrodeposited on iron by using a preliminary arsenic or antimony dip, and nickel on aluminum by using a ferric chloride dip.

Remarkable Pitting of Electroplating, Oliver P. Watts. Gen. Meeting Am. Electrochem Soc., Apr. 3-5, 1919, paper 5, pp. 51-53, 1 fig. Study of irregular pitting in some lead platings led writer to attribute it to air dissolving in electrolyte while it was resting over night, which on cooling was expelled as minute air bubbles on work when bath was heated up by passage of current.

Storage Batteries

Chemical Phenomena in Lead Storage Batteries (Recherches sur le fonctionnement chimique de l'accumulateur au plomb), Ch. Féry. Bulletin de la Société Francaise des Electriciens, vol. 9, no. 77, Feb. 1919, pp. 85-96. Study of what are termed inconsistencies of double sulphate theory in the light of laws of electrolysis. Also in Bulletin de la Société d'Encouragement pour l'Industrie Nationale, vol. 131, no. 1, Jan-Feb. 1919, pp. 92-98.

ELECTROPHYSICS

A. C. Waves, Harmonics

Direct Harmonic Analysis of Alternating Current Waves by Mechanical or Electrical Resonance (Sur l'analyse harmonique directe de l'onde des courants alternatifs par résonance mécanique ou electrique), André Blondel Annales de Physique, series 9, vol. 10, Nov.-Dec. 1918, pp. 195-354, 47 figs. Starting out to measure current, measurement of tension is effected by branching apparatus to terminals of non inductive rheostat placed in series in circuit. Writer states that in harmonic analysis mechanical resonance of vibrating galvanometer is less subject to errors than electrical resonance method.

Arc Electrodes, Temperature of

Temperature of Arc Electrodes (Détermination de la température aux electrodes de l'arc), A. Hagenbach and K. Langbein. Archives des Sciences Physiques et Naturelles, year 124, vol. 1, Jan.-Feb. 1919, pp. 48-54. Experiments apparently show that anodes of metallic arcs (Ag, Cu, Fe, Ni, W) become heated to ebullition temperature but not the cathodes; when oxidation of metal has taken place, temperature rises to ebullition temperature of metallic oxide.

Circuits

Properties of Electrical Circuits Considered as Having No Resistance (Sur les propriétés des circuits électriques dénués de resistance), G. Lippman. Revue Générale de l'Electricité, vol. 5, no. 5, Feb. 1, 1919, pp. 163-165. Advantages of disregarding resistance in establishing general laws of electric action in long circuits. Writer concludes that the laws thus established are static laws. Before the Académie des Sciences. Also in Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 2, Jan. 13, 1919, pp. 73-78.

Electrolytic Safeguards Against Overcharge

Electric Discharge on the Surface of a Solid Electrolyte, Was. Sulejkin. Phys. Rev., vol. 13, no. 3, Mar. 1919, pp. 197-208, 5 figs. Theory of electrolytic safeguards against over tension; dependence of value of critical tension upon the concentration of the electrolyte for different solutions; photomicrographs; behavior of aluminum anode up to critical tension explained.

Overhead Lines

Electrical Constants of Overhead Lines (Costanti elettriche per il calcolo delle condutture aeree), Renzo Norsa. Elettrotecnica, vol. 5, no. 33, Nov. 25, 1919, pp. 470-477, 10 figs. Diagrams and tables showing values of resistance, impedance and reactance of various circuits.

Polyphase Currents

Theory of Polyphase Currents (Théorie des Courants polyphasés), Philippe Banneux. Société Belge des Electriciens, vol. 32, 1915-1916, 1917-1918, pp. 11-91, 8 figs. Generalization of principles involved in investigations with two-phase and three-phase currents. A trigonometric series which permits addition of sines of arcs in arithmetical progression between any two limits is introduced in computations and expressions for electrical quantities are thereby developed.

Selectivity of Circuits

Process and Device for Increasing the Selectivity of Electric Circuits (Procédé et dispositifs pour accroitre la sélectivité des circuits électriques), M. I. Pupin and E. H. Armstrong. Revue Générale de l'Electricité, vol. 5, no. 7, Feb. 15, 1919, pp. 270-274, 10 figs. No. 485533 and 20499. Object is to increase selectivity of circuits which are the seat of periodically variable electric vibrations, particularly of radio-telegraphic installations.

Wehnelt Tube

The Relation of Potential Distribution to Hysteresis Effect in the Wehnelt Tube, R. A. Porter. Phys. Rev., vol. 13, no. 3, Mar. 1919, pp. 189-196, 7 figs. Three stages in discharge of vacuum tube with CaO cathode identified and potential distribution curves for one pressure and heating current obtained for each stage.

FURNACES

Air-Tight Furnaces

English Electric Furnace Developments, F. J. Moffett. Blast Furnace & Steel Plant, vol. 7, no. 4, Apr. 1919, pp. 169-170. On high efficiency and high temperature possibilities and reduction of heat losses by air-tight furnaces.

Arc Furnaces

Development of the Electric Arc Furnace (Perfezionamenti nei forni elettrici ad arco), E. Thovez. Elettrotecnica, vol. 5, no. 33, Nov. 25, 1918, pp. 477-481, 3 figs. History of various types, particularly Héroult and Bassanese.

Steel Furnaces

Iron and Steel Electric Furnaces, J. Bibby. Electrical Review, vol. 84, no. 2150, Feb. 7, 1919, pp. 166-167, 2 figs. Writer advocates single arc for steel making. (Continuation of serial.) Before Manchester Assn. Engrs.

Temperature Uniformity

Temperature Uniformity in an Electric Furnace, John F. Ferguson. Chem. & Metal lurgical Eng., vol. 20, no. 6, March 15, 1919, pp. 283-288, 9 figs. Method of manufacturing laboratory electric furnaces producing uniform temperature from end to end of core.

See also MECHANICAL ENGINEERING, *Foundries (Malleable Foundry).*

GENERATING STATIONS

Alternators in Parallel

Operation of Alternators Connected in Parallel (Etude sur la marche en parallèle des alternateurs), M. de Marchena. Bulletin de la Société Française des Electriciens, vol. 9, no. 76, Jan. 1919, pp. 17-42, 2 figs. Study of conditions under which existing theories, specially the researches of Cornu, Blondel and Boucherot, are applicable. Also in Revue Générale de l'Electricité, vol. 5, no. 11, Mar. 15, 1919, pp. 405-415, 2 figs.

Canada

Statistical Analysis of the Central Electric Stations of Canada. Power, vol. 49, no. 9, March 4, 1919, pp. 309-310. Figures showing amounts of power, capital invested, salaries and wages paid, with data on hydroelectric power.

Central Stations in West

Data on Central Stations in the West. Jl. Electricity, vol. 42, no. 5, Mar. 1, 1919, pp. 215-216. Figures issued by Bur. of Census on central electric light and power stations in New Mexico, Oregon, Nevada and Utah.

GENERATORS AND MOTORS

Armatures

Design of Small Direct-Current Armatures, C. R. Wylie. Elec. World, vol. 73, no. 12, Mar. 22, 1919, pp. 571-575, 8 figs. Methods of designing small armatures based upon both test data and theory developed for larger machines.

Asynchronous Machines

Asynchronous Generators and Converters (Generatrici asincrone e macchine convertitrici), Luigi Lombardi. Elettrotecnica, vol. 6, no. 6, Feb. 25, 1919, pp. 110-114, 1 fig. Characteristic curves of Gadda converters. (Continued.)

Ball Bearings

The Use of Ball Bearing for Electrical Machinery, H. M. Trumbull. Can. Machy., vol. 21, no. 2, Jan. 9, 1919, pp. 35-38, 12 figs. Argues that ball bearings enable builder to use smaller air gap and enhance efficiency of machines.

Commutation

Phenomena of Commutation (Phénomènes de la commutation), J. Rezelman. Société Belge des Electriciens, vol. 31, Aug.-Dec. 1914, pp. 599-632, 14 figs. Experimental determination of impedance of section of drum armature and its mutual induction with neighboring sections and the fieldmagnets, under various conditions; oscillograms showing shape and simultaneous values of tension between sections and current under brushes, for various arrangements of brushes and under different ratios b/B.

D. C. Generators

Causes of Direct-Current Generators Failing to Build Up Their Voltage, Robin Beach. Power, vol. 49, no. 14, Apr. 8, 1919, pp. 519-521, 5 figs. Mentions various causes why a machine may fail to come up to voltage and proposes remedies.

Effect of Interpoles on Commutation of Direct-Current Machines, R. L. Witham. Power, vol. 49, no. 9 and 10, Mar. 4 and 11, 1919, pp. 303-305 and 358-360, 15 figs. Purpose of interpoles and how they operate to effect commutation. Mar. 11: Influence of interpoles on voltage of generators, and on speed of motors.

D. C. Motors

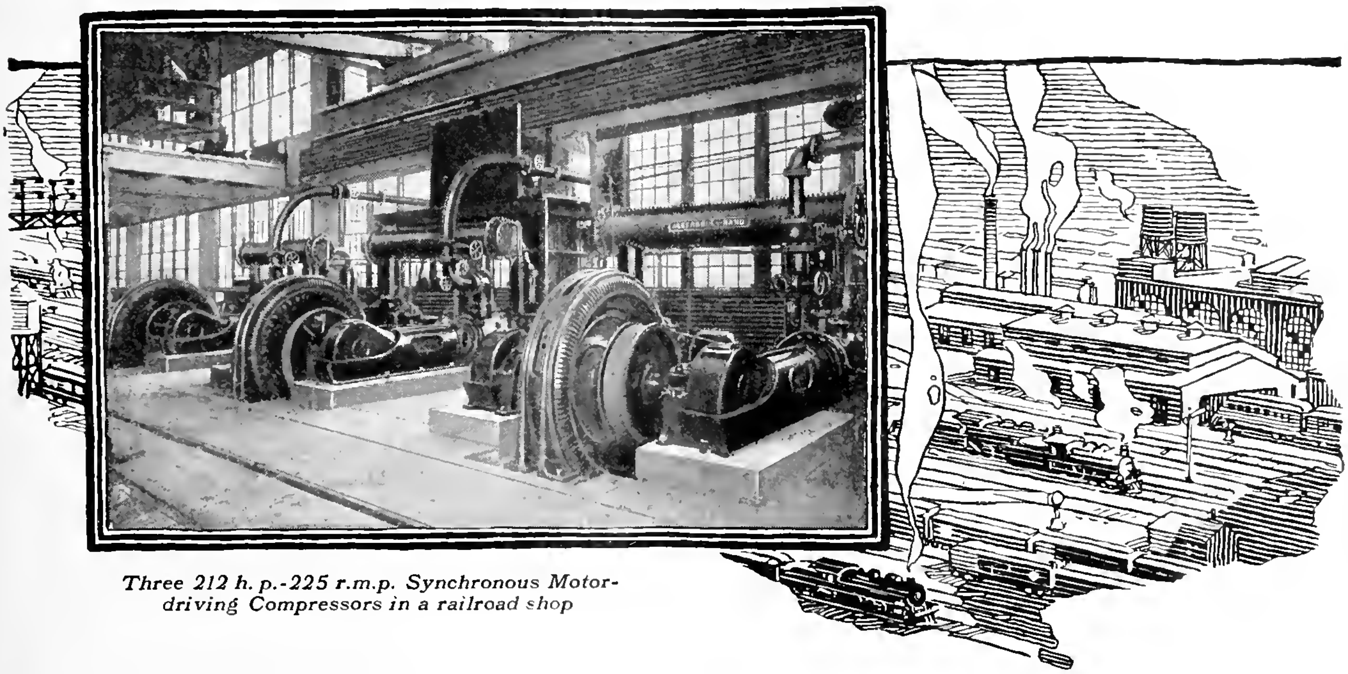
The Influence of the Distribution of Losses on the Efficiency Curves of a Continuous Current Motor, Thomas Carter. Elecn., vol. 82, nos. 9 and 10, Feb. 28 and Mar. 7, 1919, pp. 247-249 and 275-277, 8 figs. Graphs of maximum efficiency and corresponding input and output against k, with various percentages of full load efficiency. Mar. 7: Maximum output which can be got from a motor and values of input and efficiency at which it occurs. (Concluded.)

The Emeol D. C. Motors. Electrical Review, vol. 84, no. 2153, Feb. 28, 1919, pp. 250-251, 3 figs. General features, arrangement of air circulation, and temperature-rise curves of 50-hp. motor.

High Frequency Alternators

High Frequency Alternators (Les alternateurs à haute fréquence), Marius Latour. Bulletin de la Société Française des Electriciens, vol. 9, no. 77, Feb. 1919, pp. 97-114, 18 figs. Design characteristics of machines capable of furnishing directly, without supplementary transformers, the electromotive force necessary for feeding antennæ in wireless telegraphy.

The high efficiency and dependability of G-E Synchronous Motors are relied upon in many industries today.



Three 212 h.p.-225 r.m.p. Synchronous Motor-driving Compressors in a railroad shop

88,000 h.p. of synchronous motors supplied in 1918 for air compressor drive

FOR a quarter century the General Electric Company has supplied synchronous motors designed for the particular work to be done. The first ones furnished are still in continuous service requiring maximum dependability.

For industrial drives these motors are furnished from 25 to 2000 h.p. capacity with speeds from 80 to 1800 r.p.m. and are designed tc start any load met with in commercial practice without excessive current demands upon the power circuit.

The very high efficiency and dependability of these motors are due to their excellent design which is based on thorough testing of both raw materials and finished motors.

Our engineers will be pleased to supply additional information on these motors.

43-163

General Electric Company

General Office Schenectady, N.Y.

Induction Motors

Speed Regulation of Induction Motors Coupled in Cascades. (Réglage de la vitesse des moteurs d'induction par couplage en cascade), G. Darrieus. Revue Générale de l'Electricité, vol. 5, no. 7, Feb. 15, 1919, pp. 257-265, 13 figs. Survey of present designs. Suggestions to develop a more general process.

Reconnecting Induction Motors, A. M. Dudley. Power, vol. 49, no. 11, March 18, 1919, pp. 393-396, 6 figs. Summary of principles brought out in a series of thirteen articles by writer.

Mill Motors

Live Roller Motors in Steel Works, W. W. Wood. Electrician, vol. 82, no. 10, Mar. 7, 1919, pp. 269-271, 4 figs. Graphs of tests made on small mill motors without ingots on the rollers and of approximation for calculating heating effect for large mill motor. From Magnet Mag.

Large Motors for Reversing Mills. Iron & Coal Trades Rev., vol. 98, no. 2663, Mar. 14, 1919, p. 311, 2 figs. Reversing mill motors of Siemens Brothers, Dynamo Works, Ltd.; with peak load of 19,000 hp. Also in Electn. vol. 82, no. 2130, Mar. 14, 1919, pp. 302-303, 4 figs.

Nomenclature

Motors for Electric Installations (Moteurs primaires pour installations électriques). Société Belge des Electriciens, vol. 31, Aug.-Dec. 1914, pp. 636-643, 7 figs. Hydroelectric nomenclature proposed by the Commission Electrotechnique Internationale.

Turbo-Alternators

The Determination of the Efficiency of the Turbo-Alternator, S. F. Barclay, and S. P. Smith. Engineering, vol. 107, no. 2775, Mar. 7, 1919, pp. 322-326, 11 figs. Attempting to introduce method for establishing alternator efficiency based on measurement of actual losses on load. Writer shows that actual losses on load can be deduced from measurements of cooling air flowing to alternator. Paper read before Instn. Elec. Engrs.

Winding Old Armatures

Winding Coils for Old Armatures. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 578-580, 9 figs. Suggests that additional insulation is necessary at corners and between leads where clearance with core is small and large radius bends give greater flexibility for rewinding.

IGNITION APPARATUS

Ignition of Gases

The Ignition of Explosive Gases by Electric Sparks, John David Morgan. Jl. Chem. Soc., no. 675, Jan. 1919, pp. 94-104, 6 figs. Experiments with low-tension sparks under various magnetic conditions.

Plugs

Tests of Ignition Apparatus, P. M. Heldt. Automotive Industries, vol. 40, no. 11, March 13, 1919, pp. 578-579, 3 figs. Resistance to thermo-cracking and shock and gas-tightness of plugs.

Spark Gaps. Sci. Am. Supp., vol. 87, no. 2256, Mar. 29, 1919, p. 198. Suggestions concerning the construction and use of the plugs. From The Auto.

The Operation and Design of Sparking Plugs—II, H. Warren. Automobile Engr., vol. 9, no. 124, Mar. 1919, pp. 94-97, 24 figs. Details of manufacture of various types.

LIGHTING AND LAMP MANUFACTURE

Report of the Committee on Progress. Tran. Illum. Eng. Soc., vol. 13, no. 9, Dec. 30, 1919, pp. 450-511. Gas, incandescent lamps, arc lamps, lamps for projection purposes, street lighting, interior illumination, fixtures, photometry, and physical experiments.

Hotels

Illumination Notes. Hotel Rooms, W. F. Little and A. C. Dick. Tran. Illum. Eng. Soc., vol. 14, no. 1, Feb. 10, 1919, pp. 15-52, and (discussion) pp. 52-59. Survey of light intensities in rooms of Twelve New York City hotels. Data and measurements given in tabular forms.

Incandescent Lamp Manufacture

Present Status of the Industry of Incandescent Lamps (Etat actuel de l'industrie des lampes à incandescence), A. Larnaude. Houille Blanche, no. 23-24, Nov.-Dec., 1918, pp. 356-357. Abstract from communication presented before Société Internationale des Electriciens.

Legislation

Report of Committee on Lighting Legislation, L. B. Marks. Tran. Illum. Eng. Soc., vol. 13, no. 9, Dec. 30, 1919, pp. 524-527. Digest of laws on illumination.

Nomenclature

Report of the Committee on Nomenclature and Standards of the Illuminating Engineering Society for the Year 1918. Tran. Illum. Eng. Soc., vol. 13, no. 9, Dec. 30, 1919, pp. 512-523. New and revised symbols, coefficients and definitions.

Searchlights

Searchlights, Hugh M. Goody. Electrical Review, vol. 84, no. 2153, Feb. 28, 1919, pp. 227-228, 3 figs. Notes on the various designs of projector and control gear.

Spherical Candlepower

Apparatus for the Determination of the Spherical Candle-Power of a Source of Light, J. Sahulka. Elecn., vol. 82, no. 2128, Feb. 28, 1919, pp. 255-256, 2 figs. Apparatus intended to simplify usual method by obviating necessity of constructing Rousseau curve. From Elektrotechnische Zeitschrift.

Standards

Illumination and Some of Its Fundamental Considerations, H. A. Tinson. Tran. South African Instn. Elec. Engrs., vol. 9, part 11, Dec. 1918, pp. 192-198. Standards of exterior and interior illumination for various buildings, roadways, thoroughfares, etc.

Street Lighting

Street Lighting in a City of Average Size, C. D. Gray and E. Hagenlocher. Elec. World, vol. 73, no. 12, Mar. 22, 1919, pp. 575-578, 6 figs. Features of ornamental system installed at South Norwalk, Conn., said to be operated with low maintenance expense.

Tungsten Lamps

Characteristic Equations of Tungsten Lamps and Their Application to the Heterochromous Photography. (Equations caractéristiques des lampes à filament de tungstène et leur application à la photométrie hétérochrome), G. W. Middlekauff and J. F. Skogland. Revue Générale de l'Electricité, vol. 5, no. 7, Feb. 15, 1919, pp. 252-256. Investigation conducted by the Bureau of Standards concerning comparison of standards. From Scientific Papers of the Bureau of Standards.

MEASUREMENTS AND TESTS

Insulators

Photographic Study of Porcelain Insulators, Harold G. Tufty. Elec. World, vol. 73, no. 6, Feb. 8, 1919, pp. 268-271, 2 figs. Polarized light employed in examination of thin sections of insulators some of which had been properly fired, while others were underfired, and still others overfired.

Lines

Note on the Tests and Measurements of Electrical Lines (Note sur les essais et mesures relatifs aux lignes électriques), L. Monchard. Revue Générale de l'Electricité, vol. 5, no. 9, Mar. 1, 1919, p. 352, 1 fig. Arrangement suggested in L. Puget's scheme given in R. G. E. Oct. 19, 1918, pp. 563-565, to eliminate η, which is not considered in that scheme.

Magnetic Testing

Frequency of Current Reversals in Magnetic Testing, A. W. Smith. Mich. Technic, vol. 31, no. 1, Mar. 1918, pp. 18-24, 3 figs. Effect of various methods for demagnetization.

Photometry

Photometric Apparatus for Measuring the Illuminating Value of Fluctuating Sources of High Candlepower (Flares, Parachute Lights, etc.), A. P. Trotter. Illuminating Engr., vol. 11, no. 11, Nov. 1918, pp. 253-259, 3 figs. and (discussion) vol. 11, no. 12, Dec. 1918, pp. 269-276, 1 fig. Method and apparatus devised by society.

Repairmen's Testing Apparatus

Curing Electric Troubles. Motor Age, vol. 35, no. 12, Mar. 20, 1919, pp. 22-24, 11 figs. General testing apparatus for repairmen.

Transformers, Instrument

Field Testing of Instrument Transformers, H. M. Crothers. Elec. World, vol. 73, no. 11, March 15, 1919, pp. 516-519, 2 figs. Experiences with the Agnew method are said to have shown it to be valuable for tests conducted at place of installation.

POWER APPLICATIONS

Heating

Electric Heating in Houses (Le chauffage à l'électricité des maisons d'habitation), Augustin Frigon. Revue Trimestrielle Canadienne, vol. 4, no. 16, Feb. 1919, pp. 371-383, 1 fig. Efficiency and cost.

Difficulties in Electric House Heating, Joseph F. Merrill. Jl. Electricity, vol. 42, no. 5, Mar. 1, 1919, pp. 212-214. Figures showing comparative cost of central steam heating and electric heating. Writer concludes electric house heating is not a practicable load for the average power company.

Principles of Inductive Heating With High Frequency Currents, E. F. Northrup. Gen. Meeting Am. Electrochem. Soc., Apr. 3-5, 1919, paper 8, pp. 71-159, 29 figs. Theory of this method of heating and accounts of methods employed and actual results obtained in tests and experiments conducted at Palmer Phys. Lab., Princeton Univ.

Hospital

Some Electrical Features of New San Francisco Hospital. Elec. Rev., vol. 74, no. 13, Mar. 29, 1919, pp. 493-496, 5 figs. Municipal institution with power plant, silent-call signals, electric elevators, electric clocks, modern laundry and kitchen equipment, electrotherapeutic and laboratory apparatus, etc.

Loading Machinery

Electricity as Applied to Bulk Material Handling Boats. Freight Handling & Terminal Eng., vol. 5, no. 3, Mar. 1919, pp. 102-105, 10 figs. History of application of electricity to loading and unloading coal and ore. Paper read before Soc. Terminal Engrs.

Paper Making

Making Paper by Electricity. Jl. Electricity, vol. 42, no. 6, Mar. 15, 1919, pp. 260-261, 3 figs. Outline of reservoir, penstock and power plant.

Quarrying

Quarrying and Working Stone by Electricity. Stone, vol. 40, no. 3, Mar. 1919, pp. 120-122, 2 figs. Detail of Westinghouse quarry equipment.

Steel Plants

Electric Steel Plant; Features of Plant Design, W. F. Sutherland. Can. Machy., vol. 21, no. 10, Mar. 6, 1919, pp. 225-228, 8 figs. Layout of electrical apparatus in a large electric-steel plant.

See also MECHANICAL ENGINEERING, *Machine Shop (Electric Drive).*

POWER GENERATION

Hydroelectric Plants

See Power Generation, Mechanical Engineering.

STANDARDS

Lightning Rods

New Standards of the Swiss Association of Electricians (Les nouvelles normes de l'association suisse des électriciens), S. Frid. Industrie Electrique, vol. 28, no. 640, Feb. 25, 1919, pp. 72-73. Relates to installation and maintenance of lightning rods.

Polyphase Voltages

The Standardisation of Polyphase Voltages, R. Rudenberg. Elecn., vol. 82, no. 10, Mar. 7, 1919, pp. 272-273, 2 figs. Comparison of recent suggestions for standardized voltages. From Elektrotechnische Zeitschrift, Nov. 24, 1918.

TELEGRAPHY AND TELEPHONY

Amplifiers

The Use of Impedance, Capacity, and Resistance Couplings in High-Frequency Amplifiers, J. Scott-Taggart. Wireless World, vol. 6, no. 71, Feb. 1919, pp. 628-633, 8 figs. Receiving circuits without intermediary transformers or oscillatory circuits between the valves.

Vacuum-Tube Amplifiers, MacC. Batsel. Elec. World, vol. 73, no. 12, Mar. 22, 1919, pp. 568-570, 9 figs. Detection by use of vacuum-tube amplifiers of weak telegraphic ground currents and stray telephonic currents.

Antenna

Note on the Fundamental Wave and the Harmonics in a Homogenous Antenna and also a Non-Homogenous Antenna (Note sur l'onde fondamentale et les harmoniques dans une antenne homogène et dans une antenne non homogène), L. Dubar. Revue Générale de l'Electricité, vol. 5, no. 8, Feb. 22, 1919, pp. 284-289, 5 figs. Conclusions of the question derived on article R. G. E., vol. 4, no. 11, Sept. 14, 1918, p. 363.

Call Letters

International Wireless Administration. Wireless World, vol. 6, no. 71, Feb. 1919, pp. 609-610. Sugestion in regard to allocation of station call letters.

Direction Finders

Radio Direction-Finding Apparatus, A. S. Blatterman. Elec. World, vol. 73, no. 10, Mar. 8, 1919, pp. 464-467, 11 figs. Use of loop antenna in guiding airplane flight and general principles affecting design of receiving loops.

Field Stations

Recent Developments in Field Station Apparatus. Wireless World, vol. 6, no. 72, Mar. 1919, pp. 656-662, 7 figs. Technical details of damped and continuous wave transmitters and receivers.

Fires

Fires Caused by Hertzian Waves (Incendies provoqués par les ondes hertziennes), Georges Le Roy. Génie Civil, vol. 74, no. 7, Feb. 15, 1919, pp. 133-134, 1 fig., Industrie Electrique, vol. 28, no. 640, Feb. 25, 1919, pp. 78-79, and Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 4, Jan. 27, 1919, pp. 224-227, 1 fig. Specially constructed Hertzian resonator with which writer studied possibilities of fire being produced by wireless waves traversing iron bodies accidentally disposed in form of resonator.

Military Radio

Military Radio Communication, A. D. Cameron. Elec. World, vol. 73, no. 11, March 15, 1919, pp. 521-525, 3 figs. Organization of a wireless telephone and telegraph system of the signal corps.

Norwegian Stations

Great Wireless Stations of the World, Julius Galster. Wireless World, vol. 6, no. 71, Feb. 1919, pp. 591-595, 6 figs. Norwegian radio station.

Photographs

The Design and Construction of Apparatus for the Wireless Transmission of Photographs. Wireless World, vol. 6, no. 72, Mar. 1919, pp. 685-690, 16 figs. Details of the various apparatus used. (Continuation of serial.)

Poulsen System

Poulsen System of Radiotelegraphy (Il sistema di radiotelegrafia "Poulsen"), G. Pession. Elettrotecnica, vol. 6, no. 7, Mar. 5, 1919, pp. 126-134, 18 figs. System is based on property of electric arc to determine electrical oscillations in circuit comprising capacity and self-inductance.

Receivers

Super-Sensitive Receivers, Wireless World, vol. 6, no. 71, Feb. 1919, pp. 598-600, 2 figs. Types 50 and 55 evolved by Marconi Company.

Telegraphs

Ground Telegraphy in the World War, Willis L. Winter, Jl. Electricity, vol. 42, no. 5, Mar. 1, 1919, pp. 210-211, 3 figs. Principles of ground telegraphy and conditions of operation.

Telephones

The Sonority of Telegraph and Telephone Lines and a New Type of Damper (La Sonorita dei Fili telegrafici e telefonici e un nuovo tipo di sordina). Elettricista, vol. 8, no. 4, Feb. 15, 1919, pp. 25-28, 7 figs. Instrument which grips hanging wire at predetermined point in its length.

System Protecting Telephone Lines Against Trolley Wires (Los sistemas de protección contra la caida de los hilos telefónicos sobre las lineas aéreas de los tranvias eléctricos), Eng. Aigouy. Energia Eléctrica, vol. 21, no. 2, Jan. 25, 1919, pp. 17-20. Answers to questionnaire sent out to railway companies by International Union of Brussels. (To be continued.) From Electricien, Paris.

Circuits with Zero Mutual Induction, William W. Crawford. Telephony, vol. 76, no. 13, Mar. 29, 1919, pp. 15-18, 11 figs. Reduction of inductive interference in telephone circuits; forms of constructions and calculations and tentative design for greatest refinement of balance against induction. Paper before Am. Inst. Elec. Engrs.

The Multiple Interurban Telephone of Strassburg (Le multiple téléphonique interurbain de Strasbourg). Revue Générale de l'Electricité, vol. 5, no. 9, Mar. 1, 1919, pp. 335-339, 2 figs. Schemes of connections and account of construction.

Transmitters

Radio Transmitters of Synchronous Rotary Spark-Gap Type, Millard C. Spencer. Elec. Rev., vol. 74, nos. 12 and 13, Mar. 21 and 29, 1919, pp. 456-458, and 497-499, 11 figs. Theory of simple transmitter; diagram of equivalent circuit of radio transmitter; use of vector diagram for analyzing test results. First and second articles.

Undamped Oscillations

Undamped Electrical Oscillations of Short Wave Length (Oscillations électriques non amorties de courte longueur d'onde), Gutton and Touly. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 5, Feb. 3, 1919, pp. 271-274, 1 fig. and Revue Générale de l'Electricité, vol. 5, no. 11, Mar. 15, 1919, pp. 415-416, 1 fig. Apparatus developed at laboratories of military radio-telegraphy, while examining application of lamp valves with three electrodes for the generation of long waves employed in wireless telegraphy.

Vacuum Bulb

On Reading on Mr. Nozoye's "Vacuum Bulb" (in Japanese), T. Kikuchi. Denki Gakkwai Zasshi, no. 367, Feb. 10, 1919.

TRANSFORMERS, CONVERTERS, FREQUENCY CHANGERS

Rectifier

An Electro-Magnetic Alternating Current Rectifier, George F. Haller. Sci. Am. Supp., vol. 87, no. 2248, Feb. 1, 1919, pp. 76-78, 15 figs. Type designed for construction in amateur laboratory.

Transformer Connections

Transformer Connections for Power Transmission, Gordon Kribs. Power House, vol. 12, no. 3, Mar. 1919, pp. 69-73, 19 figs. Transformer connections in common use and characteristics of resulting circuits.

Transformer Mounting

Standardization of Transformer Mounting, W. C. Blackwood. Elec. World, vol. 73, no. 12, Mar. 22, 1919, pp. 578-581, 9 figs. Tables and drawings specifying methods of hanging and spacing the units mounted on poles or on consumers' premises.

TRANSMISSION, DISTRIBUTION, CONTROL

Electricity Supply

A New Era in Power Transmission, Louis Bell. Elec. World, vol. 73, no. 13, Mar. 29, 1919, pp. 631-632. Believes that development of water power, establishment of stations at mines and wider interconnection are necessary for proper industrial development of the country and for the social betterment of labor.

The Past, Present, and Future of Electricity Supply. Electrical Review, vol. 84, no. 2150, Feb. 7, 1919, pp. 163-165. Problem dealt with on a national basis. Discussion at meeting of Manchester Assn. Engrs.

Projects of Great Distribution Systems of Electrical Energy in Germany, Holland and Sweden (Les projects de création de très grands réseaux de distribution d'énergie électrique en Allemagne, Hollande et Suède). Revue Générale de l'Electricité, vol. 5, no. 9, Mar. 1, 1919, pp. 353-354. Official communication of the French Government.

Electricity Supply at Birmingham. Elec. Rev., vol. 84, no. 2154, Mar. 7, 1919, pp. 255-257, 4 figs. Installation of additional generating plant of two 5000-kw. B.T.H. turbo-alternators.

Line

Reliability of a Transmission Line (in Japanese), M. Shibuzawa. Denki Gakkwai Zasshi, no. 367, Feb. 10, 1919.

Poles

Extending the Life of Wood Poles, Charles R. Harte. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 554-559, 13 figs. Description of various methods used and discussion of their relative advantages, based on manner in which different preservatives keep out and destroy germs.

Potential Regulators

Compensated-Type Potential Regulators, Arthur H. Ford, Paul E. Mead and Guy W. Thomas. Elec. World, vol. 73, no. 13, Mar. 29, 1919, pp. 620-623, 13 figs. Connections for using compensated potential regulators for power factor and voltage correction at load; tests to determine dependence of action of regulator upon influence of line constants.

Power Circuits

Determination of Economical Power Circuits, P. O. Reyneau. Elec. World, vol. 73, no 10, Mar. 8, 1919, pp. 471-473, 3 figs. Method of deriving curves showing when two circuits become more economical than one as load increases. Fixed charges are balanced against saving of line loss when new conductors are added.

Substations

A Year of the Automatic Substation at Butte, E. J. Nash. Elec. Ry. Jl., vol, 53, no. 12, Mar. 22, 1919, pp. 565-567, 6 figs. Maintenance cost of first year.

Static Condenser Installation at the Stoughton Sub-Station of the Brockton Edison Company, W. A. Forbush. Stone & Webster Jl., vol. 24, no. 3, Mar. 1919, pp. 195-199, 3 figs. How Edison Electric Illuminating Co. solved the problem of feeding new sections in district supplied by system already loaded to capacity.

VARIA

International Electrotechnical Commission

The International Electrotechnical Commission (La comisión electrotécnica internacional), German Niebuhr. Boletin de la Asociación Argentina de Electro-Técnicos, vol. 4, no. 10, Oct. 1918, pp. 840-850, 1 fig. History, development and work. (Continuation of serial.)

Civil Engineering

BRIDGES

Concrete Arch Bridges in Canada

Concrete Arch Bridges in Canada. Contract Rec., vol. 33, no. 13, Mar. 26, 1919, pp. 275-279, 8 figs. Historical review of Canadian bridge building and reference list of reinforced-concrete arch spans.

Concrete Slab Bridge

Re-Enforced Concrete Slab Bridge Design, Based on Tests of Full-Sized Slabs, A. T. Goldbeck. Can. Engr., vol. 26, no. 10, March 6, 1919, pp. 280-281, 2 figs. Tests were conducted at Bureau of Public Roads. From Public Roads.

Design

Bridge Engineering. Surveyor, vol. 55, no. 1412, Feb. 7, 1919, pp. 129-130. On future loads and dangers of faulty design.

Erection

Cantilever Erection of Draw in Open Position While Old Draw Serves as Fixed Span. Eng. News Rec., vol. 82, no. 12, Mar. 20, 1919, pp. 567-569, 6 figs. Swing-span part of Union Pacific Bridge over Missouri at St. Joseph; old span during work carried traffic.

Bridge Substructure Construction with Concrete Caissons Sunk by Open Excavation Method, L. W. Scov. Eng. & Contracting, vol. 51, no. 13, Mar. 26, 1919, pp. 317-319, 3 figs. Experiences of Chicago, Burlington & Quincy R. R. Paper presented before Western Soc. Engrs.

Highway

Concrete and Steel Bridges, John W. Towle. Better Roads & Streets, vol. 8, no. 10, Oct. 1918, pp. 371-372. Economic advantages of good roads. Address delivered before North Carolina Good Roads Assn.

Painting

Maintenance and Painting of Highway Bridges, Charles D. Snead. Eng. & Contracting, vol. 51, no. 13, Mar. 26, 1919, pp. 306-307. Classification of structures according to structural conditions; maintenance and cost of painting.

Railway and Highway Bridge

Move Bridge Spans 136 Feet Endwise on Car Trucks. Eng. News Rec., vol. 82, no. 11, Mar. 13, 1919, pp. 530-532, 4 figs. Combined railway and highway bridge of the Union Pacific Ry.

Strengthening

Strengthening Railway Bridges, W. J. Doak. Commonwealth Engr., vol. 6, no. 6, Jan. 1, 1919, pp. 191-197, 10 figs. Details of various bridges erected throughout Queensland, Australia. Paper read before Inst. Civil Engrs.

Track-Elevation Bridge

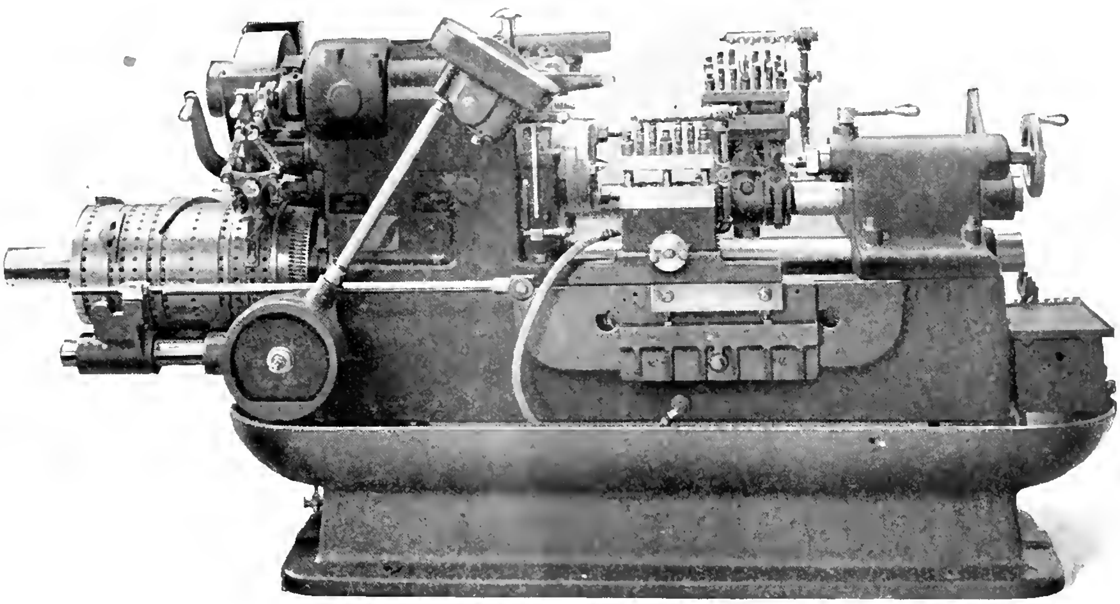
Omaha Track-Elevation Bridges Vary in Type to Meet Local Conditions. Egr. News Rec., vol. 82, no. 8, Feb. 20, 1919, pp. 380-382, 3 figs. Types of bridge superstructure and floor of Missouri Pac. R. R.

Vertical-Lift Bridge

Mechanical Features of Vertical-Lift Bridge, J. A. L. Waddell. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 379-381, 4 figs. Details of a 260-ft. double-track lift span at Louisville, Ky.

Viaducts

Design and Construction of Reinforced Concrete Viaducts on North Toronto Subdivision,



Canadian Pacific Railway, B. O. Eriksen and H. S. Deubelbeiss. Can. Ry. & Mar. World, no. 253, March 1919, pp. 109-113, 7 figs. Dimensions, details, and method of calculating moments in towers.

BUILDING AND CONSTRUCTION

Arch Analysis

Arch Analysis by a Method Using Variable Elastic Weights, F. J. Dulude. Eng. News Rec., vol. 82, no. 10, March 6, 1919, pp. 471-473, 3 figs. Tabular form intended to simplify computation of summations required in solution of arch problem by influence lines.

Architects

Does the Architect Function as He Should? Robert D. Kohn. Am. Architect, vol. 115, no. 2253, Feb. 26, 1919, pp. 291-296. Résumé of program of Post-War Committee on Architectural Practice, Am. Inst. Architects.

Automobile Storage Structure

The New Automobile Center, Social Hall Avenue, Salt Lake City. Am. Architect, vol. 115, no. 2252, Feb. 19, 1919, pp. 281-287, 13 figs. Reinforced-concrete 3-story structure used for storage of automobiles.

Barracks

A Barracks Built in a Hurry, Parker R. Whitney. Univ. Colo. Jl. Eng., vol. 15, no. 2, Jan. 1919, pp. 11-19, 4 figs. Main barracks built for Students' Army Training Corps to accommodate 350 men.

Brick

Shallow Brick Stand Up Well on Cement-Sand Base. Eng. News Rec., vol. 82, no. 8, Feb. 20, 1919, pp. 378-379, 4 figs. Service given by patching bricks on ramps of Pa. Station, N. Y.

Dams

See Earthwork, Rock Excavation, etc., p 26a.

Dry Dock

Building a Floating Dry Dock in Well Laid Out Yard. Eng. News Rec., vol. 82, no. 1 , Mar. 20, 1919, pp. 552-554, 6 figs. Cableway assisted by whirler and derrick car keeps heavy timbers ready for carpenter crews; large b saws and cutoffs; frame handled on two-way roller system.

Elevators

Floating Pneumatic Grain Elevators. Engineer, vol. 127, no. 3296, Feb. 28, 1919, pp. 206-208, 7 figs. Elevators have a maximum capacity of about 100 tons per hour each, when working in wheat.

Chicago & North Western Ry. Co.'s Grain Elevator, W. H. Finley. Eng. World, vol. 14, no. 6, Mar. 15, 1919, pp. 15-19, 5 figs. Handling capacity is 1,766,000 bu. per day. Location permits grain to be received and shipped both by rail and water.

Engine House

A Rectangular Reinforced Concrete Engine House. Ry. Age, vol. 64, no. 14, Apr. 4, 1919 pp. 891-892, 3 figs. Design to replace old brick and timber building in location where space for expansion was restricted.

Factory

Modern Factory Construction, B. A. Williams. Aeronautics, vol. 16, no. 280, Feb. 26 1919, pp. 226-227, 3 figs. Example illustrates use of Reliance standard steel sashes.

Building a Home for an Industry. Am. Architect, vol. 115, no. 2257, Mar. 26, 1919, pp. 467-475, 15 figs. Studies and projected design of buildings of dye-manufacturing concern are presented as illustration of procedure in designing an industrial structure.

Flat-Slab Construction

Design of Exterior Panels in Flat Slab Construction, Albert M. Wolf. Eng. World, vol. 14, no. 6, Mar. 15, 1919, pp. 11-14, 5 figs. Details of spandrel strips in flat-slab floors; examples of typical interior and exterior panels in accordance with Acme design standards.

Floors

Some Pointers on How to Finish a Concrete Floor, William McGinnis. Eng. News Rec., vol. 82, no. 10, March 6, 1919, pp. 477-478. Notes on use of screens and treatment of aggregate and surface.

Foundations

Anchor Bolts for Foundations, Terrell Croft. Natl. Engr., vol. 23, no. 4, Apr. 1919, pp. 175-179, 11 figs. Dimensions and weights of materials used. (To be continued).

Hotels

The Hotel Pennsylvania, New York. Am. Architect, vol. 115, no. 2253, Feb. 26, 1919, pp. 297-306, 14 figs. Said to be largest in world.

Housing

Quantity House Production Methods, Construction Branch, Emergency Fleet Corporation. Am. Architect, vol. 115, no. 2254, Mar. 5, 1919, pp. 353-358, 20 figs. Organization of Housing Section. (To be continued).

Suggested Solution of Housing Problem. Contract Rec., vol. 33, no. 6, Feb. 5, 1919, pp. 119-121. Advanced by British Roy. Sanitary Inst.

Tilbury Housing—Present and Future. Surveyor, vol. 55, no. 1415, Feb. 28, 1919, pp. 159-161, 9 figs. Scheme providing for building workers' homes rapidly.

A Chepstow Housing Scheme, William Dunn and W. Curtis Green. Jl. Roy. Inst. British Architects, vol. 26, no. 2, Dec. 1918, pp. 25-38 and (discussion) pp. 38-43, 6 figs. Site is about 28 acres in extent. Details of layout of streets, number of houses per acre and other particulars are given.

Housing: The Architects' Contribution, Raymond Unwin. Jl. Roy. Inst. British Architects, vol. 26, no. 3, Jan. 1919, pp. 49-59 and (discussion) pp. 60-64, 13 figs. Various types of houses are examined from point of view of convenience and comfort.

Financing the Expected Boom in the Building Industry—III. Am. Architect, vol. 115, no. 2251, Feb. 12, 1919, pp. 241-243. Efforts of Government authorities to encourage building construction.

The Preparation of Housing Schemes, A. G. Wheeler. Surveyor, vol. 55, nos. 1412, 1413 and 1415, Feb. 7, 14 and 26, 1919, pp. 127-128, 144 and 162. Recommendations to municipal engineers and surveyors. (Concluded)

Mortar Under Pressure

Injecting Mortar Under Pressure (Les appareils pour l'injection du mortier sous pression), L. Biette. Génie Civil, vol. 74, no. 7, Feb. 15, 1919, pp. 121-126, 15 figs. Features and operation of various types with reference to their utilization in the construction of Paris subway.

Hotel Lincoln, Indianapolis, Ind. Am. Architect, vol. 115, no. 2251, Feb. 12, 1919, pp. 238-240, 11 figs. Situated on triangular lot measuring 150 ft. and 187 ft. street fronts.

Roofs

Zinc as a Roof Covering, William Hutton. Metal Worker, no. 2360, Mar. 21, 1919, pp. 370-371, 5 figs. Suggestions based upon practice in European countries.

School

The Scarboro-on-Hudson School, Welles Bosworth. Am. Architect, vol. 115, no. 2258, Apr. 2, 1919, pp. 477-480, 4 figs. Architectural features.

Methods, Economies and Standardization in Preparation of Plans for School Buildings, Clarence E. Dobbin. Eng. & Contracting, vol. 51, no. 13, Mar. 26, 1919, pp. 313-314, 1 fig. Plea for uniform practice. From paper presented before Mun. Engrs. of City of N. Y.

Sheet Steel

A Structural Material Made of Thin Sheet Steel. Am. Architect, vol. 115, no. 2251, Feb. 12, 1919, pp. 249-254, 12 figs. Describes joists, studs, sills and caps made of said material embedded in concrete.

Standardization

The Standardization of Building Products, Robert D. Kohn. Am. Architect, vol. 115, no. 2258, Apr. 2, 1919, pp. 498-500. Advocated as means to insure production speed in housing work.

Storage Tanks

Storage Tanks made of Reinforced Concrete, F. W. Frerichs. Chem. & Metallurgical Eng., vol. 20, no. 5, March 1, 1919, pp. 234-236, 3 figs. Details of large installation of concrete tanks; tests on permeability for water and ammoniacal liquor; drawings, construction, and costs. Before Chicago meeting, Am. Inst. Chem. Engrs.

Design and Construction Features of Concrete Oil Storage Tanks, C. W. Van Dyke. Eng. & Contracting, vol. 51, no. 13, Mar. 26, 1919, pp. 304-305, 4 figs. Particulars of 182,-000-gal. fuel-oil tank of American Brakeshoe Co.

Structures, Theory of

On a New Principle in the Theory of Structures, George F. Swain. Proc. Am. Soc. Civil Engrs., vol. 45, no. 3, Mar. 1919 (paper and discussion), pp. 75-91, 13 figs. Mathematical formula to determine angular rotation at a point, derived by a method analogous to that used for finding the deflection for any point of a structure in any given direction.

Swimming Pools

Swimming Pools for Public Schools, C. E. Dobbin. Am. Architect, vol. 115, no. 2253, Feb. 26, 1919, pp. 319-328, 8 figs. Arrangement and details.

Warehouse

Industrial Building Construction in Trafford Park. Engineer, vol. 127, no. 3292, Jan. 31, 1919, pp. 98-100, 11 figs. Warehouse with capacity of 10,000 tons of frozen produce, erected to comply with the requirements of Ministry of Food.

See also MECHANICAL ENGINEERING, Pipe (Corrosion).

CEMENT AND CONCRETE

Blended Portland Cement

An Investigation of Blended Portland Cement. School of Mines & Metallurgy, University of Missouri, vol. 4, no. 4, May, 1918, pp. 1-76, 33 figs. Study of behavior of sand-blended cement. From tests at Mo. School of Mines.

Cement Gun

Tests on Cement Gun Products, Bryan C. Collier. Contract Rec., vol. 33, no. 10, March 5, 1919, pp. 216-218. Modulus of rupture determined for slabs having various ages.

Consistency Measurement

Concrete Consistency Measured by New Device, Herbert A. Davis. Eng. News Rec., vol. 82, no. 13, Mar. 27, 1919, pp. 603-605, 6 figs. Method developed for construction of concrete ships determines amount of water to use in field operations.

Flue Dust

Double Salts of Calcium and Potassium and Their Occurrence in Leaching Cement Mill Flue Dust, E. Anderson. Jl. Indus. & Eng. Chemistry, vol. 11, no. 4, Apr. 1, 1919, pp. 327-332, 3 figs. Formation of potassium penta-calcium sulfate.

Holland

New Dutch Instructions Relative to Reinforced Concrete Construction (Les nouvelles instructions hollandaises relatives aux instructions en béton armé). Génie Civil, vol. 74, no. 9, Mar. 1, 1919, pp. 171-173, 10 figs. Regulations published by the Roy. Inst. Engrs.

Mixing

Effect of Quantity of Mixing Water and Curing Conditions on the Strength and Wear of Concrete. Eng. & Contracting, vol. 51, no. 13, Mar. 26, 1919, pp. 309-312, 9 figs. Deductions obtained from tests made at Lewis Inst., Chicago.

Pneumatic Concreting

The Pneumatic Method of Concreting, H. B. Kirkland. Jl. Western Soc. Engrs., vol. 23, no. 5, May 1918, pp. 319-349 and (discussion), pp. 349-355, 23 figs. Method consists in blowing batches of concrete through a pipe from a central point of supplies to their place in the concrete forms.

Precast Construction

Concrete Moulding Plant, Pennsylvania R. R. Ry. Rev., vol. 64, no. 12, Mar. 22, 1919, pp. 425-432, 14 figs. Facilities placed in operation for the purpose of manufacturing precast reinforced-concrete members for erection of buildings and construction of bridges, and also for turning out concrete fence posts and telegraph poles.

Quick-Hardening Cement

The Hydraulic Properties of the Calcium Aluminates, P. H. Bates. Jl. Am. Ceramic Society, vol. 1, no. 10, Oct. 1918, pp. 679-696, 5 figs. Tests are reported to have shown that it is possible to make cements giving 24 hours strengths as high as those developed by Portland Cements in 28 days. This quick-hardening cement is said to consist of calcium aluminate high in alumina (55 to 75 per cent.).

Reinforced-Concrete Structures

Theory of Reinforced-Concrete Structures (Calculo de estructuras de hormigón armado), Julio R. Castiñeiras. Universidad Nacional de la Plata, Publicaciones de la Facultad de Ciencias Fisicas, Matemáticas y Astronómicas, vol. 1, no. 35, May 1918, pp. 373-454, 55 figs. Formulæ and theorems applicable to beams under simple flexure. (Continuation of serial.)

Reinforcing Elements

New Accepted Form of Reinforcing Metal in Concrete (Sur une nouvelle forme canonique des massifs armés), Charles Rabut. Comptes rendus des séances de l'Académie de Sciences, vol. 168, no. 1, Jan. 6, 1919, pp. 50-53. Value of plates in reinforcing; claimed advantages over bars.

Slag Concrete

Blast Furnace Slag in Concrete and Reinforced Concrete, J. E. Stead. Eng. World, vol. 14, no. 6, Mar. 15, 1919, pp. 25-27: Oxidation of sulphides in slag; conditions under which slag concrete has failed; suggestions for production of reinforced concrete.

Underground Work

The Use of Concrete in Underground Work. Chem. Eng. & Min. Rev., vol. 11, no. 125, Feb. 5, 1919, pp. 130-132, 3 figs. Work done by Wallaroo and Moonta Mining & Smelting Co., Ltd.

Underwater Work

Methods of Depositing Concrete under Water. Eng. & Contracting, vol. 51, no. 13, Mar. 26, 1919, pp. 307-308. Report submitted at convention of Am. Ry. Eng. Assn.

Wasteful Construction

Useless Waste in Concrete Construction Due to Legal Requirements, W. Stuart Tait. Am. Architect, vol. 115, nos. 2250 and 2251, Feb. 5 and 12, 1919, pp. 211-212 and 254-256. Ruling for column design adopted by Am. Concrete Inst. Feb. 12: Comparison of concrete regulations with Lloyd's factors of safety for ship structures.

See also MECHANICAL ENGINEERING, Materials of Construction (Beams, Reinforced Concrete, Mortars, Cement, Lime).

EARTHWORK, ROCK EXCAVATION, ETC.

Cofferdams

Cofferdam and River Wall Construction, T. E. Thain. Practical Engr., vol. 59, no. 1672, Mar. 13, 1919, pp. 124-127, 16 figs. Particulars of dam designed for dock works, where it is proposed to dam up a dock.

Dams

The East Canyon Creek Dam, A. F. Parker. Proc. Am. Soc. Civil Engrs., vol. 45, no. 3, Mar. 1919. Papers and Discussions, pp. 93-113, 4 figs. Design and construction of arched concrete dam.

Conditions of Stability and Suggested Design for Wooden Dam Built on Sand. Eng. & Contracting, vol. 51, no. 11, Mar. 12, 1919, pp. 261-262. Dam is to be built on very permeable sand.

Recent Multiple Arch Dams, John S. Eastwood. Jl. Electricity, vol. 42, no. 6, Mar. 15, 1919, pp. 263-266, 3 figs. Data on four structures of this type.

Dredge, Hydraulic

Operating a Hydraulic Dredge Under Difficulties, Albert S. Fry. Eng. News Rec., vol. 82, no. 9, Feb. 27, 1919, pp. 410-414, 7 figs. Excavation used to dig out log-filled earth in channel which had been filled up by slipping of spoil banks.

Excavation, Balancing

Economic Balancing of Highway Excavation by a Semi-Graphic Method, Dudley S. Babcock. Eng. News-Rec., vol. 82, no. 8, Feb. 20, 1919, pp. 361-364, 6 figs. Device called "trace curve," used in designing Storm King Highway of N. Y. State Highway Dept.

Fills

Dump Cars and Wagons Enlarge Railway Fills. Eng. News-Rec., vol. 82, no. 9, Feb. 27, 1919, pp. 419-420, 2 figs. Methods of raising and widening fills.

Tunnel, Hudson River

Vehicular Tunnels under the Hudson River, Martin Schreiber. Jl. Franklin Inst., vol. 187, no. 3, Mar. 1919, pp. 273-288, 9 figs. Necessity of constructing proposed tunnel is emphasized principally by the fact that out of a total of 40,000 miles of terminal railway within the metropolitan area, 29,000 miles are on the Jersey side. Views, details, and location of various projects for tunnel and bridge are given.

Tunnels

Principles and Scientific Rules for Designing Long Tunnels Under Water Courses (Principes et règles scientifiques pour l'établissement des longs tunnels sous nappe d'eau), Charles Rabut. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 4, Jan. 27, 1919, pp. 220-221. Subordination of plans, profile, and all other details of project to preventing inundation, or in case it happens, to avoid loss of human life by providing suitable means such as accessory exploration galleries, etc.

Regulations for Constructing Long Tunnels Under Water Cources (Règles à suive pour l'établissement des longs tunnels sous nappe d'eau), M. Lecornu. Génie Civil, vol. 74, no. 6, Feb. 8, 1919, p. 114. Rules intended to prevent inundation. Read before the Académie des Sciences.

ROADS AND PAVEMENTS

Asphaltic Concrete Pavements

Two Types of Hard Surface Roads Successfully Employed in New Hampshire, Frederic E. Everett. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 80-81. Service given by asphaltic concrete pavement.

Bituminous Pavements

Efficiency of Bituminous Surfaces and Pavements Under Motor Truck Traffic, Prevost Hubbard. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 98-100. Rates increasing efficiency of bituminous types as follows: Bituminous surfaces, bituminous macadam, bituminous concrete, sheet asphalt and asphalt block. Also in Good Roads, vol. 17, no. 11, Mar. 15, 1919, pp. 117-119; Can. Engr., vol. 26, no. 10, Mar. 6, 1919, pp. 117-119.

Brick Pavements

Present Status of Brick Pavements Constructed with Sand Cushions, Cement Mortar Beds and Green Concrete Foundation, Wm. M. Acheson. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 103-105. Changes in design since 1915.

Canada

Roads in Coleman Township, H. T. Routly. Can. Engr., vol. 26, no. 10, Mar. 6, 1919, pp. 274 and 286-287, 4 figs. History, developments, improvements and organization of personnel. Ontario Land Surveyors.

Chicago

Recent Developments in Design and Construction of Pavements in Chicago, H. J. Fixmer. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 92-94, 2 figs. Layout of central concrete-mixing plant.

Cost-Keeping

Cost-Keeping for Highway Contractors, Albert B. Gillette. Can. Engr., vol. 26, no. 10, Mar. 6, 1919, pp. 282-283. Recommends securing daily reports that show the total unit cost of every item on which contractor has bid a unit price. Before Convention of the Am. Road Builders' Assn.

Some Points to Observe in the Construction of Concrete Roads, William W. Cox. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 105-106. Concerning drainage, preparation of sub-grade, selection of materials, workmanship and designing.

Dustless Roads

Smooth, Dustless Roads Maintained by Gang System. Eng. News Rec., vol. 82, no. 11, Mar. 13, 1919, pp. 526-528, 3 figs. Bituminous carpet placed on macadam highways said to prove satisfactory metal on such roads.

Financing

Efficient Methods of Promoting Bond Issues, S. E. Bradt. Good Roads, vol. 17, no. 13, Mar. 29, 1919, pp. 139-140. Considerations generally taken up in issuing state bonds for highway construction.

Drainage

Drainage Methods for Country Roads. Contract Rec., vol. 33, no. 6, Feb. 5, 1919, pp. 110-114, 2 figs. Discussion of foundations and drainage suitable to various soils found in highway construction.

Foundations

Road Foundations, Drainage and Culverts, George Hogarth. Contract Rec., vol. 33, no. 10, March 5, 1919, pp. 197-199, 19 figs. Examples of various constructions. Also in Can. Engr., vol. 26, no. 10, Mar. 6, 1919, pp. 284-285, 6 figs.

Grade Crossings

Grade Crossing Elimination in New York City, William L. Selmer, Mun. Engrs. Jl., vol. 5, no. 3, Mar. 1919, pp. 1-21, 10 figs. Progress made by Public Service Commission for First District during the 11½ years of its existence.

Granite Block Pavements

Some Suggestions on the Proper Construction of Granite Block Pavements, Albert T. Rhodes. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 106-110, 7 figs. Suggestions based on differences of production in Northern and Southern quarries.

Indiana

Provisions of Proposed Indiana Highway Law. Good Roads, vol. 17, no. 7, Feb. 15, 1919, pp. 58-60. Summary of test of bill introduced in Indiana Senate providing for establishment of state highway commission, state system of highways and state highway fund.

Kansas

Some features of Highway Work in Kansas, M. W. Watson. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 86-88, 3 figs. State Highway Commission created by legislature.

Labor

Sources of Supply of Unskilled Labor for Highway Work. Good Roads, vol. 17, no. 10, Mar. 8, 1919, pp. 111 and 114-115. From reports of state highway departments, city departments and contractors, it is stated that there will be sufficient supply of unskilled labor for highway projects during coming season and at wages lower than those prevailing during season of 1918. Committee report of Am. Road Builders' Assn. Also in Eng. News Rec., vol. 82, no. 10, Mar. 6, 1919, pp. 466-467.

Macadam Road Reconstruction

Building New Concrete Shoulders to Preserve the Old Macadam Roads of Maryland, John N. Mackall. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 79-80, 3 figs. Preserving old macadam roads constructed before coming of extremely heavy motor traffic of to-day.

The Reconstruction of Worn Out Macadam Upon a State Road in Rhode Island, I. W. Patterson. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 81-83, 1 fig. Difficulties encountered in reconstructing; imperfect drainage; resurfacing macadam roads built originally with coarse-grained granite.

Maintenance

System Without Red Tape Makes Success of Day Labor Road Maintenance. Eng. News Rec., vol. 82, no. 8, Feb. 20, 1919, pp. 384-386, 3 figs. Weekly return form to show status of each job.

Methods of Maintaining Highway Systems Prior to Construction by State or County, Frederic E. Everett. Good Roads, vol. 17, no. 13, Mar. 29, 1919, pp. 137-138. Practice followed at New Hampshire. Paper presented before Am. Road Builders' Assn.

Michigan

Low Hauling Cost and No Waste of Material on Construction of Michigan Roads. Better Roads & Streets, vol. 8, no. 10, Oct. 1918, pp. 380-381, 1 fig. Layout of Lake Shore road job; number of men required; material-handling system.

Repairs

Repairing Pavement Openings. Mun. Jl., vol. 46, no. 12, Mar. 22, 1919, pp. 215-218, 2 figs. Practices of various cities as to methods of restoring pavements.

Streets

Street Systems; Their Relation to Highways Outside of Urban Districts, Nelson P. Lewis. Good Roads, vol. 17, no. 9, Mar. 1, 1919, pp. 99-100. Concerning exit from a city to system of roads outside it. Presented at convention Am. Road Builders' Assn.

Street Cleaning

Recommended Procedure in Cleaning Streets in Rochester, N. Y., James W. Routh. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 90-91. Criticism of common methods of street cleaning, with reference to conditions in Rochester.

Surfaces

Build Permanent Road Surfaces, R. Crawford Muir. Contract Rec., vol. 33, no. 10, March 5, 1919, pp. 200-204, 17 figs. Analysis of methods of constructing the various types of surfaces; importance of gaging amount of future traffic.

Temperature of Road Surfaces

High Relative Temperatures of Pavement Surfaces, G. S. Eaton. Eng. News-Rec., vol. 82, no. 13, Mar. 27, 1919, pp. 633-634, 3 figs. Observations made by engineer of Universal Portland Cement Co. on surface temperatures of various types of surfacing and variation between these surfaces and adjacent localities.

Vitrified Brick

Vitrified Brick Construction for Heavy Motor-Truck Traffic, W. M. Acheson. Eng. News-Rec., vol. 82, no. 10, March 6, 1919, pp. 467-468. Advantages claimed for brick pavements of monolithic type.

Width

Wider Pavements Needed by Motor Vehicles at Curves, G. S. Eaton. Eng. News-Rec., vol. 82, no. 10, March 6, 1919, pp. 461-462, 3 figs. Graph of theoretical and recommended widths of lane for various radii.

SANITARY ENGINEERING

Camp Drainage

Camp Drainage and Sanitation, W. H. Beswick. Jl. Roy. Sanitary Inst., vol. 39, no. 2, Oct. 1918, pp. 70-74. Outline of work done at Salisbury Plain Camps.

Garbage Disposal

Baltimore Adopts Feeding Method for Garbage Disposal. Eng. & Contracting, vol. 51, no. 11, March 12, 1919, pp. 258-259, 1 fig. Specifications of city of Baltimore garbage disposal. Also in Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 96-98.

Suggestions for Improvements in Apparatus and Appliances for Dealing with House Refuse, James Jackson. Surveyor, vol. 55, no. 1415, Feb. 28, 1919, pp. 180-181. Concerning the assignation of special charges and daily removal of refuse.

Sewage Disposal

Sewage Disposal Works at London, Ontario, Willis Chipman. Can. Engr., vol. 26, no. 10, March 6, 1919, pp. 269-274, 12 figs. Two-story, non-reversible sedimentation tanks and enclosed filters with fixed spray nozzle.

St. Catherine's Relief Sewage System, D. H. Fleming. Contract Rec., vol. 33, no. 8, Feb. 19, 1919, pp. 178-181, 12 figs. Details of tunnels, manholes, etc.

Sewage Disposal at Manchester. Surveyor, vol. 55, no. 1408, Jan. 10, 1919, pp. 17-18. Activated sludge investigations; results of operation.

Sewers

Rideau River Intercepting Sewer, Ottawa, L. McLaren Hunter. Can. Engr., vol. 36, no. 1, Jan. 2, 1919, pp. 105-106 and 111, 6 figs. Map showing areas drained; method of supporting pipe under fill; operations in laying 40-in. concrete pipe.

Street Cleaning

Street Cleaning Methods. Mun. Jl., vol. 46, no. 6, Feb. 8, 1919, pp. 101-104, 4 figs. Sweeping by machine and hand, flushing and sprinkling. Report of Rochester Bureau of Municipal Research. (To be continued.)

WATER SUPPLY

Conduit Design

Economical Section of Water Conduit for Power Development, Cary T. Hutchinson. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 369-371, 2 figs. Method of determining economical section of water conduit for supplying water to a power plant.

Factory Water Supply

What It Pays to Know About Factory Water Supply, Charles L. Hubbard. Factory, vol. 22, no. 3, March 1919, pp. 453-455, 3 figs. On insuring against well going dry.

Flood Control

Colorado River Flood Control by Storage, E. C. La Rue. Eng. News Rec., vol. 82, no. 10, March 6, 1919, pp. 456-461, 7 figs. It is claimed that reservoirs at various sites would so cut flood at Yuma as to control Imperial Valley.

Freezing of Reservoir

The Freezing of a Reservoir Outlet Works, Gilbert Christie. Surveyor, vol. 55, no. 1408, Jan. 10, 1919, pp. 19-20, 2 figs. Operations to restore supply. Paper before Instn. Water Engrs.

Railway Water Supply

Modern Water Supply Plant on Southern Railway System. Railroad Herald, vol. 23, no. 3, Feb. 1919, pp. 52-54, 1 fig. Sedimentation basin of 2,500,000 gal. capacity, installed to provide improved water supply for operation of locomotives.

Water Treatment

Results of Application of Chloramine Process to Catskill (Esopus) Water of New York City, Frank E. Hale. Eng. & Contracting, vol. 51, no. 11, March 12, 1919, pp. 262-264, 3 figs. Process consists in combining bleach with ammonia just before applying to the water treated.

Chlorine Absorption and the Chlorination of Water, Abel Wolman and Linn H. Enslow. Jl. Indus. & Eng. Chem., vol. 11, no. 3, Mar. 1, 1919, pp. 209-213, 3 figs. Results of the study of the question of chlorination control in Maryland.

Design and Performance of the Iron Removal Plant for Laundry Water at State School, Sparta, Wis., W. G. Kirchoffer. Mun. & County Eng., vol. 56, no. 3, Mar. 1919, pp. 88-90, 3 figs. Removal of iron from deep-well water by aeration, coke and treated sand filter.

Water-Works Operation

Water Works Operation: Reservoir Maintenance. Mun. Jl., vol. 46, no. 6, Feb. 8, 1919, pp. 105-107, 1 fig. Collection of sediment in reservoirs and methods of removing it.

WATERWAYS

Canals

Construction of a Lateral Canal at Allier (Construction de'un canal latéral à l'Allier), René Tavernier. Houille Blanche, nos. 23-24, Nov.-Dec., 1918, pp. 337-338. Study of a joint commission of the Departments of Allier and Puy de Dome.

The Rhone-Rhine Canal (Le canal du Rhône au Rhin.) Huille Blanche, nos. 23-24, Nov.-Dec., 1918, pp. 334-336. History of project. From Bulletin Hebdomadaire de la Navigation et des Ports Maritimes, Aug. 4 and 11, 1918.

The Cher Hydraulic System (Contribution à la détermination du régime hydraulique du Cher), P. Morin. Revue Générale de l'Electricité, vol. 5, no. 11, Mar. 15, 1919, pp. 417-418, 3 figs. Concerning supplying Berry canal at point near bridge from Cher to Montluçon.

Floods

On the Gradually Varying Movement and the Propagation of Floods (Sur le mouvement graduéllement varié et la propagation des crues), Edmond Maillet. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 5, Feb. 3, 1919, pp. 266-268. Suggests modification of Boussinesq's equations.

Inland Waterways

What the Goverament Did in Inland Waterway Navigation. Eng. News-Rec., vol. 82, no. 10, March 6, 1919, pp. 480-481. Abstract of Director General of Railroads' report on progress made during 1918 on waterways taken over by his administration.

Mississippi River

Revival of Mississippi River Traffic—III, M. von Pagenhardt. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 295-297, 4 figs. Structural features of barge terminal at St. Louis; arrangements of cargo-handling machinery.

Stream Flow

Stream Flow and Percolation Water, Samuel Hall. Surveyor, vol. 55, nos. 1408 and 1409, Jan. 10 and 17, 1919, pp. 15-16 and 35-37, 5 figs. Sources of supply due to percolation. Paper before Instn. Water Engrs.

Stream Regulation

Meteorology and Stream Regulation, W. F. V. Atkinson. Can. Engr., vol. 36, no. 1, Jan. 2, 1919, pp. 101-103, 1 fig. Chart showing direct effect of weather on flow and indirect effect through protection of forest growth; utilization of data concerning wind, temperature, precipitation and barometer records in fighting forest fires.

RECLAMATION AND IRRIGATION

Concrete

Concrete Box Flume Carried Across Gulch on Trestle, A. W. Collins. Eng. News Rec., vol. 82, no. 10, March 6, 1919, pp. 463-464, 2 figs. Substitution of concrete for steel in irrigation system at Hawaii.

Ditch

Hydraulic Efficiency of a Drainage Ditch for Five Different Channel Conditions, C. E. Ramser. Eng. News Rec., vol. 82, no. 11, Mar. 13, 1919, pp. 522-523, 5 figs. Data of various channels.

Drainage

Land Drainage in Cambridgeshire. Engineer, vol. 127, no. 3295, Feb. 21, 1919, pp. 174-176, 10 figs. Details of work on river and fen improvement.

Irrigation Canal Cleaning

Removing Algæ from a California Irrigation Canal, E. Court Eaton. Eng. News-Rec., vol. 82, no. 8, Feb. 20, 1919, pp. 382-383, 1 fig. Rotary screen with water jet and heavy dose of agent.

Morocco

The Hydraulic Wealth of Occidental Morocco (Les richesses hydrauliques du Maroc Occidental), P. Penet. Houille Blanche, nos. 23-24, Nov.-Dec., 1918, pp. 338-351, 8 figs. Possible industrial utilization; utilization of waters in agriculture; suggested program of study.

Reclamation Work

Reclamation Work on the Key System, Chas. Christopher. Elec. Traction, vol. 15, no. 3, Mar. 15, 1919, pp. 189-190 and 194-195, 4 figs. Installation of electromagnet and Brownhoist for handling scrap material.

SURVEYING

Point Determination

Errors in Position of a Point (Sur les erreurs de situation d'un point), Alf Guldherg. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 3, Jan. 20, 1919, pp. 153-155. Concerning probability of error in position of point determined by rectangular coördinates in series of continuous observations.

Mining Engineering

BASE MATERIALS

Clay

A Method for the Determination of Air in Plastic Clay, H. Spurrier. Jl. Am. Ceramic Soc., vol. 1, no. 10, Oct. 1918, pp. 710-713, and (discussion) pp. 714-715, 2 figs. Apparatus for quantitative determination of air.

Fluorspar

Fluorspar, Percy A. Wagner. South African Jl. Industries, vol. 1, no. 16, Dec. 1918, pp. 1516-1520. Manner of occurrence and sources of supply; dressing, preparation, and commercial uses; position and prospects of the South African fluorspar industry.

Fluorspar in the Ordovician Limestone of Wisconsin, Rufus Mather Bagg. Bul. Geol. Soc. Am., vol. 29, no. 3, Sept. 1918, pp. 393-397, 1 fig. Writer's findings while examining galena limestone quarries at Neenah.

Limestone

Labor Saving at Limestone Quarries, Oliver Bowles. Dept. of Interior, Bureau of Mines, Technical Paper 203, 26 pp. Methods and types of equipment that have been tried and approved by quarry operators.

Phosphates

Industry of Mineral Superphosphates (L'industrie des superphosphates minéraux). Chimie & Industrie, vol. 2, no. 2, Feb. 1, 1919, pp. 123-128, 4 figs. Technical study of French industry which produced two million tons of superphosphates during the twelve months preceding August 1914.

Silica

High-Grade Silica Materials, R. J. Colony. N. Y. State Museum Bul., nos. 203, 204, Nov. and Dec. 1917, pp. 5-29, 15 figs. From field, laboratory and microscopic studies of high-silicia rock, writer concludes that within the borders of the State of New York there is rock of good quality, easy of access, capable of being readily quarried, and which may be used for glass making, ferrosilicon manufacture, silica refractories and tube mill liners and pebbles.

GEOLOGY AND MINERALS

Age of Earth

The Age of the Earth, Harlow Shapley. Sci. Am. Supp., vol. 87, no. 2246, Jan. 18, 1919, pp. 34-35 and 42-43. Discussion of recent evidence from Geology, Astronomy and Physics. From Publ. Astron. Soc. of the Pacific, no. 177.

Anorthosite, Adirondack

Adirondack Anorthosite, William J. Miller. Bul. Geol. Soc. Am., vol. 29, no. 3, Sept. 1918, pp. 399-462. Structures, relations and origin. References are made to anorthosite of other regions and to Bowen's hypothesis, which latter writer pronounces untenable.

Columbia

The Guamoco District of Columbia—I, S. Ford Eaton. Eng. & Min. Jl., vol. 107, no. 12, Mar. 22, 1919, pp. 513-515, 3 figs. History of mining in Columbia and details of travel and physical characteristics of mineral deposits.

Crystallography

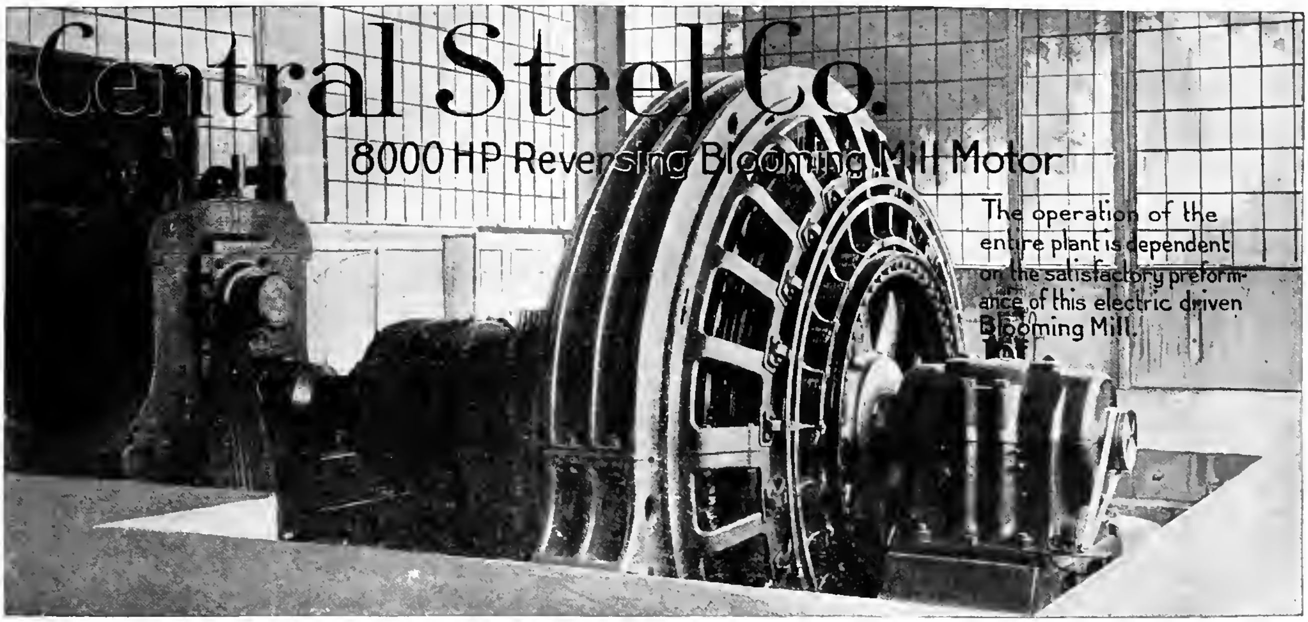
A Laboratory Method of Teaching Elementary Crystallography, Joseph E. Pogue. Am. Mineralogist, vol. 3, nos. 10 and 11, Oct. and Nov. 1918, pp. 179-182 and 193-194. Writer's practice in connection with a course in elementary crystallography at Northwestern University.

Crystallography of some Canadian Minerals. Albite, Titanite, Scapolite and Polycrase, Eugene Poitevin. Am. Mineralogist, vol. 4, nos. 2 and 3, Feb. and Mar. 1919, pp. 11-13 and 22-26, 7 figs. Specimens consisted of cavernous masses composed of association of augite, phlogopite and feldspar.

The Classification of Mimetic Crystals, Edgar T. Wherry and Elliot Q. Adams. Jl. Wash. Acad. Sci., vol. 9, no. 6, Mar. 19, 1919, pp. 153-157. Table showing types of mimetic phenomena, with three prefixtures proposed.

Kansas Crystalline Rocks

Geologic History of the Crystalline Rocks of Kansas, Raymond C. Moore. Bul. Am. Assn.



Westinghouse Has Furnished More than 65% of all Reversing Mill Equipments in the United States.

From the standpoint of economy and reliability of operation, excessive friction load is objectionable.

The friction load on a steam-driven mill may continue unchecked until the roller is warned of its presence by "low steam" or failure of the engine to pull the load.

For this reason useless and objectionable waste may be needlessly prolonged; all the while bearing spindles, boxes and necks continue to wear, the severity increasing with the increase in friction load. Hence, power consumption and maintenance climb upward.

Electric drive provides the roller means of instantly locating the source of trouble or irregularities in rolling operations—enabling the roll turner to take immediate corrective measures. Both the load and the power requirements of the various passes are easily and accurately determined, thus assisting in developing the most favorable rolling schedule. Consequently, power consumption, maintenance and costly shutdowns are held to the minimum

Among our early electric installations is that at the Central Steel Company —an 8000 H. P. Reversing Blooming Mill. The operation of the entire plant is dependent upon the satisfactory performance of this electric-driven blooming mill.

The broad experience of Westinghouse engineers is available in the solution of your power problems.

Westinghouse Electric & Mfg. Co.
East Pittsburg, Pa.

WESTINGHOUSE ELECTRIC

Westinghouse

—The Pioneer—

Petroleum Geologists, vol. 2, pp. 98-113. Material of crystalline mass is described as being for the most part a typical granite containing quartz porphyry and chlorite schist.

Datolite

Famous Mineral Localities: The Datolite Locality Near Westfield, Massachusetts, Earl V. Shannon. Am. Mineralogist, vol. 4, no. 1, Jan. 1919, pp. 5-6. General properties of minerals.

Earthquake Waves

Earthquake Waves and the Interior of the Earth. Engineering, vol. 107, no. 2774, Feb. 28, 1919, pp. 266-267, 1 fig. Facts revealed by examination of seismograph and experimental work of the motion of compressional longitudinal waves in ropes.

Eastern Pennsylvania Highlands

Precambrian Sedimentary Rocks in the Highlands of Eastern Pennsylvania, Edgar T. Wherry. Bul. Geol. Soc. Am., vol. 29, no. 3, Sept. 1918, pp. 375-392, 14 figs. Types described as of ultimate sedimentary origin.

Gettysburg

Glauberite Crystal Cavities in the Triassic Rocks in the Vicinity of Gettysburg, Pa., George W. Stose. Am. Mineralogist, vol. 4, no. 1, Jan. 1919, pp. 1-4, 7 figs. Results of petrographic study of specimens.

Glacial Deposits and Reservoir Sites

Relation of Landslides and Glacial Deposits to Reservoir Sites in the San Juan Mountains, Colorado, Wallace W. Atwood. Department of the Interior, U. S. Geological Survey, Bul. 685, 38 pages, 25 figs. Mountain canyons and deposits commonly found in them; geological conditions associated with the lakes in the mountains.

Kansas Geology

Geological Conditions in Central Kansas, Irving Perrine. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 70-97. Review of general geology with notes on the structural conditions.

Litchfield, Maine

Field Relations of Litchfielite and Soda-Syenites of Litchfield, Maine, Reginald A. Daly. Bul. Geol. Soc. Am., vol. 29, no. 3, Sept. 1918, pp. 463-470, 2 figs. Account of field work.

Maine

Famous Mineral Localities: Mt. Mica, Mt. Apatite and other Localities in Maine, James G. Manchester and William T. Bather. Am. Mineralogist, vol. 3, no. 9, Sept. 1918, pp. 169-174, 5 figs. Observations made by writers in automobile trip through localities.

Oolites in Shale

Oolites in Shale and Their Origin, W. A. Tarr. Bul. Geol. Soc. Am., vol. 29, no. 3, Sept. 1918, pp. 587-600, 2 figs. Oolites in shale constituting Papo Algie beds are believed to be due to direct precipitation of colloidal silica introduced into the saline, shallow waters by streams flowing from adjacent land areas.

Peneplains, Appalachian

Ages of Peneplains of the Appalachian Province, Eugene Wesley Thaw. Bul. Geol. Soc. Am., vol. 29, no. 3, Sept. 1918, pp. 575-586. Examination of Appalachian peneplains in light of published and unpublished data concerning buried peneplains in Atlantic and Gulf Coastal Plains.

Quartz

Fibrous Quartz from Rhode Island, Alfred C. Hawkins. Am. Mineralogist, vol. 3, no. 7, July 1918, pp. 149-151. Writer disagrees with Prof. Emerson's theory concerning origin of fibrous quartz.

River Virgin, Utah

Oil Possibilities of the River Virgin Anticline, W. F. Calvert. Salt Lake Min. Rev., vol. 20, no. 24, Mar. 30, 1919, pp. 21-23, 4 figs. Outline of geological features of region in Southwestern Utah, which is believed to possess oil deposits.

Texas, Louisiana Coastal Plain

Minerals of the Saline Domes of the Texas-Louisiana Coastal Plain, Alfred C. Hawkins. Am. Mineralogist, vol. 3, no. 11, Nov. 1918, pp. 189-192. General data of sixty-three domes mapped to date in Texas and Louisiana.

Trilobites

The Facial Suture of Trilobites, H. H. Swinnerton. Geol. Mag., vol. 6, no. 3, Mar. 1919, pp. 103-110, 2 figs. Examination of various evidences lead writer to affirm that trilobites are a compact group, the members of which at first underwent ecdysis along marginal suture

Vivianite

The Color Change in Vivianite and its Effect on the Optical Properties, Thomas L. Watson. Am. Mineralogist, vol. 3, no. 8, August 1918, pp. 159-161. Rapid change of color is said to to due to oxidation and not to inversion.

Wasatch Region, Utah

Relation of Ore Deposits to Thrust Faults in the Central Wasatch Region, Utah, B. S. Butler. Economic Geology, vol. 14, no. 2, Mar.-Apr. 1919, pp. 172-175, 3 figs. Writer's detail work in district.

COAL AND COKE

Ash Yield, Calorific Value

The Relation Between the Calorific Values and the Ash-Yields of Coal-Samples from the Same Seam, Thomas James Drakeley. Trans. Manchester Geol. & Min. Soc., vol. 36, part I, Feb. 1919, pp. 9-20, 3 figs. Plotted calorific values and ash yields of mixtures of coal with calcium carbonate and shale. Equation expressing relation between calorific value and ash percentage.

Coal Pyrites, Tennessee

The Coal Pyrite Resources of Tennessee and Tests on Their Availability, E. A. Holbrook and Wilbur A. Nelson. Resources of Tennessee, vol. 9, no. 1, Jan. 1919, pp. 60-70, 1 fig. Coöperative research of State Geol. Survey with U. S. Bur. of Mines.

Coal-Washing Machinery

The Draper Coal Washing Machine. Engineer, vol. 127, no. 3295, Feb. 21, 1919, pp. 180-181, 3 figs. Machine is intended to deal with fine classes of coal which are generally thrown away on account of difficulty in separating coal from its associated dirt; it is said machine will handle dust so fine that it will pass a 60-mesh screen.

Coke Handling

Handling of Coke, C. J. Woodhead. Gas Jl., vol. 145, no. 2912, Mar. 4, 1919, pp. 391-394, 2 figs. Figures of Huddersfield coke handling plant. Paper read before Manchester and District Junior Gas Assn.

Coke Retorts, Central System

A New Design of Vertical Retorts—the "Central" System. Gas Jl., vol. 145, no. 2912, Mar. 4, 1919, pp. 455-456, 2 figs. Design of type introduced by Firth Blakeley & Co. of Leeds.

England

The Coal Resources of England, H. H. Stoek. Black Diamond, vol. 62, no. 11, Mar. 15, 1919, pp. 298-300, 1 fig. Review showing importance and extent of Great Britain's coal deposits.

Fatalities

Coal-Mine Fatalities in the United States, Albert H. Fay. Dept. of Interior, Bur. of Mines, Jan. 1919, 61 pp. Statistics of coal-mine fatalities in 1918, by states and months; details relating to chief cause of accidents; list of permissible explosives, lamps and motors tested prior to Jan. 31, 1919.

German Coal Classification

The German System of Coal Classification and the Future Economic War—I & II. Colliery Guardian, vol. 117, nos. 3036 & 3037, Mar. 7 & 14, 1919, pp. 535-536 and 593-595, 10 figs. Study of efficiency in utilizing fuel value of coal by partial or complete gasification, direct combustion being reserved for exceptional instances. Utilizing separate products in preparation.

Knox County, Ind.

Knox County Mines and Their Coal. Black Diamond, vol. 62, no. 14, Apr. 5, 1919, pp. 376-377, 11 figs. Activities of Knox County (Indiana) Coal Operators Assn.

Nitrogen in Coal

Researches on Coal (Recherches sur la houille), Amé Pictet. Annales de Chimie, series 9, vol. 10, Nov.-Dec. 1918, pp. 249-330. Undertaken to determine in what form nitrogen is contained in coal. Samples from Montrambert (Loire) were treated with various acid and neutral solvents, notably boiling benzene.

Philippine Islands

The Mindanao Coal Mines, Monroe Woolley. Coal Age, vol. 15, no. 11, March 13, 1919, pp. 492-493, 3 figs. Operation of fuel beds in the Philippines.

Roll Crushers

Rolls for the Preparation of Coking Coals. Coal Age, vol. 15, no. 14, Apr. 3, 1919, pp. 612-615, 9 figs. Comparison of hammer mill and roll crusher.

Shaft Development

Modern Shaft Development of the Consolidation Coal Company—I & II, George W. Harris. Coal Age, vol. 15, nos. 11 and 12, Mar. 13 and 20, 1919, pp. 480-485 and 527-531, 6 figs. General details and dimensions of mine no. 87. Operations involved in mine workings by noting location of old and new gas wells.

Training of Students

The Training of Students in Coal-Mining, with Special reference to the Scheme of the Engineering Training Organization, F. W. Hardwick. Tran. Min. Inst. Scotland, vol. 40, part 8, 1918-1919, pp. 154-162. Maintenance of Central Bureau, where parents and educationalists can obtain accurate and comprehensive information relating to engineering industry and proper course to pursue on behalf of boys who are desirous of making engineering their profession.

Utah

A One-Year Retrospect of the Coal Industry of Utah, A. C. Watts. Coal Age, vol. 15, no. 14, Apr. 3, 1919, pp. 610-611. Growth of industry.

Yellowhead Coal District

The Yellowhead Coal District, S. McVicar. Coal Age, vol. 15, no. 14, Apr. 3, 1919, pp. 608-610, 4 figs. Details of operation of two coal beds on steep pitch worked simultaneously by means of balanced plane.

COPPER

Leaching

Practical Considerations in Ammonia Leaching of Copper Bearing Ores, Lawrence Eddy. Chem. & Metallurgical Eng., vol. 20, no. 7, Apr. 1, 1919, pp. 328-334, 4 figs. Plant installation and operation; leaching tanks; plate joinings, filters and inlets; piping and pumps; evaporators; details of operation; charging and extracting ore; chemical control; cost of leaching; labor, power and ammonia.

Copper Leaching, Percy R. Middleton. Chem. Eng. & Min. Rev., vol. 11, no. 125, Feb. 5, 1919, pp. 133-134, 2 figs. Methods applicable to Australian ores.

IRON

Australia

Australian Iron Ore Resources. Min. Mag., vol. 20, no. 3, Mar. 1919, pp. 150-156, 3 figs. Information relating to iron ore deposits in West Australia, New South Wales and Tasmania.

British Columbia

Utilization of Iron Ores of British Columbia. Canadian Min. Jl., vol. 40, no. 13, Apr. 2, 1919, pp. 212-213. Proposes asking British Columbia Legislature for authority to take from any of the iron ore properties of the Province a quantity of ore, not to exceed 10,000 tons in the aggregate for experimental uses.

Magnetic Concentration

Magnetic Concentration of Pyrrhotite Ores, J. P. Bonardi. Chem. & Metallurgical Eng., vol. 20, no. 6, March 15, 1919, pp. 266-270. Experiments and tests made with a Wetherill type magnetic separator.

Mexico

Iron in Mexico (El fiero en Mexico), Trinidad Paredes. Boletin Minero, vol. 6, no. 3, Sept. 1918, pp. 253-479, 1 fig. Official publication issued by Department of Industry and Labor of Mexican Government. Mining conditions and prospects are considered at length and legislation concerning exploitation of collieries and iron deposits is studied.

LEAD, ZINC, TIN

German Domination of Metal Markets

Report of Alien Property Custodian on the Metal Industry. Chem. & Metallurgical Eng., vol. 20, no. 7, Apr. 1, 1919, pp. 313-317, 3 figs. Regarding German domination of metal markets in Europe, particularly zinc and lead.

Lead, Osotopic

Notes on Osotopic Lead, Frank Wigglesworth Clarke. Chem. News, vol. 117, no. 3062, Dec. 6, 1918, pp. 370-373. Remarks on differences in atomic weight of ordinary lead and lead obtained from radio-active processes.

Northampton (Australia), Lead Ores

The Northampton Lead-Mining District, West Australia, C. M. Harris. Min. Mag., vol. 20, no. 3, Mar. 1919, pp. 140-143. Account of old lead-mining district in West Australia that showed renewed activity during war.

24 Years Carrying 50% Overload

TEN years ago the U. S. Rubber Reclaiming Co. of Buffalo installed a 50 H. P. Link-Belt Silent Chain Drive. That drive has been operating ever since, 24 hours a day carrying a 50% overload. If figured on tne basis of a ten-hour day, that drive has been in operation 24 years.

Think of it. Twenty-four years of driving efficiency—unaffected by heat, cold or dampness, carrying 50% greater load than was intended—with never a slip, the load always cushioned and never a moments idleness for chain repairs. That's Link-Belt Silent Chain Drive efficiency and service. It will prove itself "flexible as a belt, positive as a gear, more efficient than either" in your plant. Let us prove it.

Our many years of experience is at your service to help you save money in the transmission of your power. Write us. Ask for our Data Book No. 125. 206

Tin-Bearing Mineral, Pleochroism

Pleochroism in a Tin-Bearing Mineral from Siam, J. B. Scrivenor. Geol. Mag., vol. 6, no. 3, Mar. 1919, pp. 123-124. From examination of heavy concentrate of course grains of dark mineral and finer grains of ilmenite, monazite, tourmaline, zircon, and topaz.

Tin, Hydraulic Prospecting for

Hydraulic Prospecting at the Rooiberg Tin Mines, E. R. Schoch. South African Jl. & Eng. Rec., vol. 28, no. 1427, Feb. 1, 1919, pp. 501-502. Method of surface prospecting by means of hydraulic jets or monitors.

Zinc Tailings, Retreating

Retreating Zinc Tailings in Wisconsin, W. F. Boericke. Eng. & Ming. Jl., vol. 107, no. 12, Mar. 22, 1919, pp. 524-527, 2 figs. Details of 5-cell jig with settling tank.

MAJOR INDUSTRIAL MATERIALS

Manganese

Preparation of Manganese Ores, W. R. Crane and E. R. Eaton. Resources of Tennessee, vol. 9, no. 1, Jan. 1919, pp. 48-59, 2 figs. Methods employed in dry mining, washing and concentration.

The Mining and Preparation of Manganese Ores in Tennessee, W. R. Crane. Resources of Tennessee, vol. 9, no. 1, Jan. 1919, pp. 32-47, 5 figs. Different forms of deposits. Minerals found in manganese districts are pyrolusite, psilomelane and manganite.

MINES AND MINING

Accidents

Accidents at Metallurgical Works in the United States, Albert H. Fay. Dept. of Interior, Bureau of Mines, Technical Paper 215, 23 pp. Statistics during calendar year 1917.

British Columbia

Reports of British Columbia Government Mining Engineers. Can. Min. Jl., vol. 40, no. 7, Feb. 19, 1919, pp. 100-108. Review and estimate of mineral production for 1918.

Canada

Mineral Production in Canada for 1918. Contract Rec., vol. 33, no. 12, Mar. 19, 1919, pp. 264-266. Report issued by Mines Branch, Department of Mines.

Drill Attachments

The Swift Drill Attachment. South African Min. & Eng. Jl., vol. 28, no. 1430, Feb. 22, 1919, pp. 604-605, 1 fig. Description of device; tests at Van Ryn Deep and Crown Mines.

Dust Sampling

Sampling of Dust in Mine Air, J. Boyd. Eng. & Min. Jl., vol. 107, no. 9, March 1, 1919, pp. 395-396, 1 fig. Air-testing suction pump as used for dust sampling by Chamber of Mines on Witwatersrand.

Excavators

Model Mining Methods (Metodas modelos de minaria). Revista Mineira e Metalurgica, vol. 1, nos. 10, 11 and 12, Oct.-Dec. 1918, pp. 88-90, 3 figs. Experiments by North West Corporation with Lubecker excavator (German type).

Legal

Abstracts of Current Decisions on Mines and Mining, J. W. Thompson. Dept. of Interior, Bur. of Mines, Bul. 174, law serial 17, 136 pp. Reported from May to September 1918.

Uniform Mining Law for North America, T. E. Godson. Bul. Am. Inst. Min. & Metallurgical Engrs., no. 148, Apr. 1919, pp. 653-665. Mining laws of Canada represented as unassimilated to demands of industry.

Laws, Decrees and Decisions concerning Mines, Quarries, Sources of Mineral Waters, Railways in Operation, etc. (Lois, décrets et arrêtés concernant les mines, carrières, sources d'eaux minérales, chemins de fer en exploitation, etc.). Annales des Mines, vol. 7, no. 3, 1918, pp. 263-264. Documents published by Ministry of Public Works.

Details of Important Mining Bill Before the British Columbia Legislature, Robert Dunn. Coal Age, vol. 15, no. 12, Mar. 20, 1919, pp. 524-526. Provisions concerning miners' examinations, treatment of hoisting ropes and the practical elimination of all but safety lamps for miners' use.

Mining Law and Economics, David Bowen. Colliery Guardian, vol. 117, no. 3035, Feb. 28, 1919, pp. 479-480. Leases and licenses; definition of terms.

Longwall Mining

Longwall Mining in Illinois, Chester Mott. Mine & Quarry, vol. 11, no. 2, Mar. 1919, pp. 1122-1128, 6 figs. Practice in Illinois Third Vein field.

Ore-Dressing Laboratory

The Ore Dressing Laboratory of the Haileybury School of Mines, J. A. McRae. Can. Min. Jl., vol. 40, no. 3, Jan. 22, 1919, pp. 43-44. Summary of tests possible to carry out in plant.

Rescue Training

Rescue Training. Sci. & Art of Min., vol. 29, no. 17, Mar. 22, 1919, pp. 258-259. Fitness to undertake rescue work is said to be possessed by returning soldiers on account of their having been exposed, while in actual service, to constant danger.

Respirators

Industrial Use and Limitations of Respirators, Gas Masks and Oxygen Breathing Apparatus. Chem. & Metallurgical Eng., vol. 20, no. 5, March 1, 1919, pp. 220-221. Statement of Bur. of Mines.

Separation Doors

Separation-Doors at the Bottom of the Upcast Pit, Worked Automatically by Tubs attached to Endless-Rope (Undertub) Haulage, Clement Fletcher. Tran. Instn. Min. Engrs., vol. 56, part 3, Jan.-Feb. 1919, pp. 173-175. Design in which operating catch is disengaged from the tub axle when door is fully opened or closed.

Shaft Design

Shaft Design: Some Comparisons, W. L. White. South African Jl. & Eng. Rec., vol. 28, no. 1427, Feb. 1, 1919, pp. 503-504. On the various types of shafts with reference to those recently erected at South African mines.

Circular Shafts, H. Stuart Martin. Jl. South African Instn. Engrs., vol. 17, no. 7, Feb. 1919, pp. 136-147, 7 figs. Comparison of circular shafts with other types, particularly square and seven-compartment.

Seven-Compartment Rectangular Shafts, C. E. Knecht. Jl. South African Instn. Engrs., vol. 17, no. 7, Feb. 1919, pp. 127-136, 3 figs. Discusses merits in regard to safety in sinking, normal rate of sinking, ability to cope with water and other sinking difficulties, ventilation area, hoisting capacity and cost.

Shoveling

A Study of Shoveling Applied to Mining—H. G. Townsend Harley. Eng. & Min. Jl., vol. 107, no. 12, Mar. 22, 1919, pp. 520-522, 3 figs. Effect of shape of shovel and length of handle on amount of shoveling done. Influence of system of payment for work performed on individual efficiency of miners.

Notes on Rectangular Shafts at Randfontein Central G. M. Co., Ltd., and New State Areas, Ltd., W. L. White. Jl. South African Instn. Engrs., vol. 17, no. 7, Feb. 1919, pp. 148-156, 5 figs. Drawings and figures of two vertical shafts at Randfontein and at New State Area, South Africa.

Shot Drilling

Shot Drilling Around Thetford Mines, J. W. Davis. Can. Min. Jl., vol. 40, no. 3, Jan. 22, 1919, pp. 36-38, 4 figs. Prospecting work in asbestos and chromite iron deposits by Calix shot drills.

Stope Measurement

Cobar Stope Measurement Methods, W. S. Curteis. Instn. Min. & Metallurgy, Bul. 174, Mar. 13, 1919, 20 pp., 6 figs. Analysis of methods employed in measuring the stopes at Great Cobar, Ltd., New South Wales, Australia. Methods were devised primarily for measurement for payment purposes.

Taxation

Principles of Mining Taxation, Thos. W. Gibson. Bul. Am. Inst. Min. & Metallurgical Engrs., no. 148, Apr. 1919, pp. 611-620. Analysis of general systems of taxation and their application to mines, which, it is contended, have to spend part of earning in building for workers' conveniences of living in remoted regions.

Temperatures in Deep Mines

High Temperatures in Deep Mines, William Garnforth. Tran. Instn. Min. Engrs., vol. 56, part 3. Jan.-Feb. 1919, pp. 127-133. Review of reports issued by various official and scientific committees.

Tunnel Driving

Methods and Cost of Driving a 10 x 12 ft. Mining Tunnel at Copper Mountain, B. C., Oscar Lockmund. Eng. & Contracting, vol. 51, no. 12, Mar. 19, 1919, pp. 286-287, 1 fig. Driving of main haulage level at Copper Mountain Mines of Can. Copper Corp. Presented at Chicago meeting, Am. Inst. Min. Engrs.

Ventilation

Ventilation Methods in Coeur d'Alene Mines, Robert N. Bell. Min. & Sci. Press, vol. 118, no. 12, Mar. 22, 1919, pp. 397-398. Abstract from report of State Inspector of Mines.

Mine Ventilating Plant. Engineer, vol. 127, no. 3292, Jan. 31, 1919, pp. 110-111, 6 figs. Arrangements in installation driven by 300 hp., 2-cyl. tandem compound engine.

MINOR INDUSTRIAL MATERIALS

Salt

Separation of Salt from Saline Water and Mud, E. M. Kindle. Bul. Geol. Soc. Am., vol. 29, no. 3, Sept. 1918, pp. 471-487, 12 figs. Laboratory observations on behavior of salt in evaporation of saline mixtures and discussion of their geological significance.

Zirconia

Zirconia. Metal Industry, vol. 14, no. 10, Mar. 7, 1919, pp. 189-190. Its occurrence and application.

OIL

Cuba

The Geology of Cuban Petroleum Deposits, E. DeGolyer. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 133-167. Compilation of several geological, stratigraphic and structural data, and comparison with North American Mid-Continent fields.

Gasoline Content in Natural Gas

Testing Natural Gas for Gasoline Content, G. G. Oberfell, S. D. Shinkle and S. B. Meserve. Jl. Indus. & Eng. Chem., vol. 11, no. 3, Mar. 1, 1919, pp. 197-200, 6 figs. Method employs use of solid absorbing medium such as charcoal and is applicable to both lean and rich natural gas.

Geology

Value of Oil Geology in the Mid-Continent Field, Edward Bloesch. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 124-132. Value of geology is considered to depend on keeping producers out of territory where there is no chance of production at all.

India

Notes on Structure and Stratigraphy in the North-West Punjab, E. S. Pinfold. Records Geol. Survey India, vol. 49, part 3, Dec. 1918, pp. 137-159. Notes collected while prospecting for oil.

Kentucky

A Résumé of the Past Year's Development in Kentucky from a Geological Standpoint, J. R. Pemberton. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 38-52, 1 fig. Wild-cat drilling in 1917 is said to have resulted in the discovery of many new and valuable oil pools; anticlinal structure control and conditions of structures in western Kentucky are described.

Louisiana

The Oil and Gas Fields of Northern Louisiana, Mowry Bates. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 61-69. Wells are said to be costly to drill and operate in northern Louisiana and the region is not considered as attractive.

Migration Through Sedimentary Rocks

On the Migration of Petroleum through Sedimentary Rocks, A. W. McCoy. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 168-171. Concerning accepted theory that the oil has been formed from various types of animal and vegetable remains, buried in sedimentary rocks.

Santa Clara, Cal.

Tectonic Interpretation of Santa Clara Valley Petroliferous Region (Interprétation tectonique de la région petrolifère de la vallée de Santa Clara en Californie), Max Reinhard. Archives des Sciences Physiques et Naturelles, year 124, vol. 1, Jan.-Feb. 1919, pp. 63-78, 4 figs. Theoretical considerations on petroleum deposits, and Eldrige's and Arnold's studies have led writer to suggest interpretation of southern California formations particularly Santa Clara valley.

Storage

Petroleum Oils (Les essences de pétrole) A. Guiselin. Journal du Pétrole, no. 12, Dec. 1918, pp. 1-6, 3 figs. Losses due to storage and methods of preventing them. (Continuation of serial.)

Evaporation Losses of Crude Oil Decreases Gasoline Content, J. H. Wiggins. Natural Gas & Gasoline Jl., vol. 13, no. 3, Mar. 1919, pp. 89-90. Concerning evaporation losses of crude oil.

Texas

A Review of the Development in the New Central Texas Oil Fields During 1918, W. G. Matteson. Economic Geology, vol. 14, no. 2, Mar.-Apr. 1919, pp. 95-146, 7 figs. Stratigraphy, structural geology, and general tectonic relationships.

Venezuela

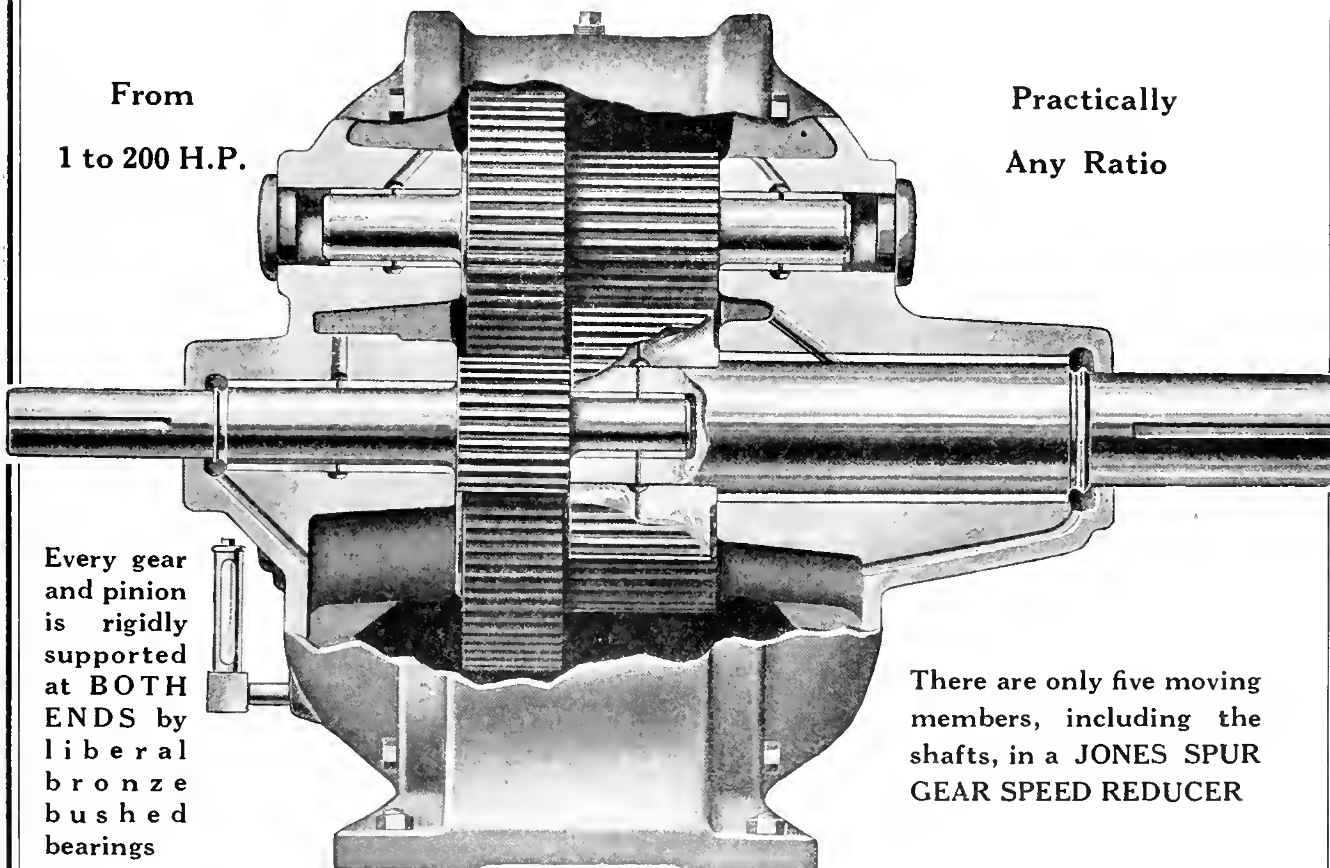
Caribbean Petroleum's Operations in Venezuela. Oil Trade Jl., vol. 10, no. 4, Apr. 1919, p. 72, 3 figs. Transportation of well casing.

COMPARE THE SIMPLICITY OF THE JONES SPUR GEAR SPEED REDUCER

With Other Speed Reducing Devices

From 1 to 200 H.P.

Practically Any Ratio



Every gear and pinion is rigidly supported at BOTH ENDS by liberal bronze bushed bearings

There are only five moving members, including the shafts, in a JONES SPUR GEAR SPEED REDUCER

All shafts are accurately ground to size.

The gears and pinions are not milled with rotary cutters, but are accurately generated, with stub teeth of 20° pressure angle (the recognized standard for automobile and truck transmissions).

The Jones Reducer is just a plain spur gear drive with no internal gears or overhung pinions involving a complicated mounting.

The consistent use of Johannson limit gages insures absolute interchangeability of parts.

Every gear, pinion and bearing is flooded with oil at all times.

Sling rings on the two extended shafts keep all of the oil in the housing.

The height of oil in the housing can be determined instantly by looking at the sight gage.

Every Reducer problem is given a complete engineering analysis, thus insuring the selection of a machine amply proportioned for the full duty to be performed.

Let us assist you in solving your reducing problems.

W. A. JONES FOUNDRY & MACHINE CO.

ESTABLISHED 1890

4400 WEST 12th ST., CHICAGO, U. S. A. NEW YORK OFFICE: 30 CHURCH ST.

Water

The Distribution of Underground Salt Water and its Relation to the Accumulation of Oil and Gas, Roswell H. Johnson. Bul. Am. Assn. Petroleum Geologists, vol. 2, pp. 174-176. On relative roles of ascending and descending waters in oil accumulation.

PRECIOUS MINERALS

Diamonds

The Latest Development of Diamond Winning in S. W. Africa. South African Jl. & Eng Rec., vol. 28, no. 1427, Feb. 1, 1919, pp. 495-496 Search for big mine under the sea; diamond recovery by dredging.

Gold Precipitation

The Theory of the Precipitation of Gold by Charcoal. A. W. Allen. Eng. & Ming. Jl., vol. 107, no. 12, Mar. 22, 1919, pp. 516-519, 2 figs. Abstracted from Bul. 171, I. M. M.

Gold Volatilization

The Volatilization of Gold. Thomas Kirke Rose. Instn. Min. & Metallurgy, Bul. 174, Mar. 13, 1919, 13 pp., 1 fig. Summary of results obtained by various investigators. Writer concludes that true volatilization of gold is so small as to be negligible at temperatures of industrial melting furnaces.

RARE MINERALS

Beryl

Famous Mineral Localities: Beryl Mountain, Acworth, N. H. Edward F. Holden. Am. Mineralogist, vol. 3, no. 12, Dec. 1918, pp. 199-200. Physical features of beryl crystals.

Famous Mineral Localities: Beryl Hill, Grafton, New Hampshire. George M. Flint. Am. Mineralogist, vol. 4, no. 3, Mar. 1919, pp. 21-22, 2 figs. Features of beryl exhibited at various museums.

Radium

Radium Production. Chas. H Viol. Science, vol. 44, no. 1262, March 7, 1919, pp. 227-228. Output of the Standard Chemical Co. of Pittsburgh from 1913-1918.

Uranium

The Determination of Uranium in Alloy Steels and Ferro-Uranium. G. L. Kelley, F. B. Myers and C. B. Illingworth. Jl. Indus. & Eng. Chemistry, vol. 11, no. 4, Apr. 1, 1919, pp. 316-317. Method for determining uranium in presence of any of the other elements now in common use in the manufacture of alloy steels.

Uranium: Its Extraction from Pitchblende. Gustave Gin. Gen. Meeting Am. Electrochem. Soc., Apr. 3-5, 1919, paper 6, pp. 55-60. Discussion of occurrence and composition of pitchblende; methods of treatment by which uranium oxide is separated from it, both when it contains vanadium and when vanadium is absent; writer's proposed method for purification, involving fusion and electric-furnace treatment to convert most of constituents into carbides followed by separation based on differing properties of carbides.

MERCURY

Condensation Losses

Fume and Other Losses in Condensing Quicksilver from Furnace Gases. L. H. Duschak and C. N. Schuette. Dept. of Interior, Bureau of Mines, Technical Paper 96, 29 pp., 8 figs. Report of experiments conducted by Federal Bur. of Mines through its station at Berkeley, Cal.

Metallurgy

BLAST FURNACES

Charging, Mechanical

Mechanical Charging of Silver Lead Blast Furnaces. L. D. Anderson Monthly Jl. Utah Soc. Engrs., vol. 5, no. 1, Jan. 1919, pp. 1-5, 3 figs. Practice of U. S. Smelting & Refining Co. at Midvale, Utah.

Gas Cleaning

New Blast Furnace Gas Cleaning Outfit. Blast Furnace & Steel Plant, vol 7, no. 4, Apr. 1919, pp 193-195, 2 figs. Ruddiman scrubber and combined cooler and dryer; cleaning apparatus combines principle of contact type of cleaner with that of scrubber type

New Dry Cleaner for Blast Furnace Gas. J. C. Barrett. Blast Furnace & Steel Plant, vol. 7, no. 4, Apr. 1919, pp 185-187, 1 fig. King-Weidlein dry gas cleaner developed at Youngstown claims many advantages over wet process; retention of sensible heat of gas; greater steam generation and higher stove temperature.

Hot-Blast Stoves

Forced Draft for Hot Blast Stoves. Oskar Simmersbach. Iron & Coal Trades Rev., vol. 48, no. 2654, Jan. 10, 1919, p. 40, 2 figs. Combats opinion that with natural draft products of combustion are not evenly distributed over whole area of chequer work. From Stahl und Eisen.

COPPER AND NICKEL

Cupro-Nickel Alloys

Cupro-Nickel. H. A. Eastick. Metal Industry, vol. 14, no. 8, Feb. 21, 1919, pp. 141-143, 3 figs. Equilibrium diagram for cupro-nickel alloys; physical properties, tensile strength, elongation curves and characteristic graph of alloy containing 15 per cent nickel.

Nickel Refining

International Nickel Company's Refining Works at Port Colborne, Ontario, W. L. Wotherspoon. Eng. & Min. Jl., vol. 107, no. 10, March 8, 1919, pp. 429-435, 11 figs. Preliminaries incidental to erection and details relating to installation of plant. An annual output of 15,000,000 lb. of nickel is expected.

FLOTATION

Differential Flotation

Differential Flotation of Lead-Zinc (Flottage différentiel de plomb-zinc). Echo des Mines et de la Métallurgie, vol. 47, no. 2616, Mar. 9, 1919, pp. 152-155, 1 fig. Bradford differential process.

Filters

An Electrically Driven Filter. E. J. Richards. Jl. Electricity, vol. 42, no. 6, Mar. 15, 1919, pp. 262-263, 2 figs. Oliver filter in use in flotation process, by Arizona Hercules Copper Company.

Wolf Patent

The Wolf Patent on Flotation. Min. & Sci. Press, vol. 118, no. 12, Mar. 22, 1919, pp. 390-392, 1 fig. Separation of metals from their ores. From text of Letters Patent No. 787,814.

IRON AND STEEL

Acid Bessemer Steel

A Technical Study of Acid Bessemer Steel. Iron Age, vol. 103, no. 10, Mar. 6, 1919, pp. 626-627. Action of manganese and its possible conservation; prevention of spitting; effect of bottom of converter. From Wisconsin Engr.

Cast Iron, Corrosion by Acids

Rupture of Cast Iron in Contact with Mixed Acid. A. C. Cumming. Jl. Soc. Chem. Indus., vol. 38, no. 3, Feb. 15, 1919, pp. 31T-32T. Experiments in connection with manufacture of trinotrotoluene.

Classification of Iron and Steel

Plan to Improve Foreign Trade Statistics. Iron Age, vol. 103, no. 11, Mar. 13, 1919, pp. 685-687. Tentative classification of iron and steel products to be used in reporting exports and imports, prepared by a committee of representatives from Bur. of Foreign and Domestic Commerce and other government organizations.

Ferrotitanium

The Beneficial Results Obtained by Introducing 25 per cent Carbonfree Ferrotitanium into Iron and Steel. Reactions, First Quarter, 1919, pp. 15-17, 7 figs. Cast-iron base of 25-ton Browning crane welded with thermit.

Flaky Steel

Observations on So-Called "Flakes" in Steel. Haakon Styri. Chem. & Metallurgical Eng., vol. 20, no. 7, Apr. 1, 1919, pp. 342-351, 41 figs. Examination of nickel-steel and carbon-steel transverse test bars showed that abnormalities in fractures were associated with impaired physical qualities and exhibited more or less minute slag inclusions.

Observations on Flaky and Woody Steel. Federico Giolitti Chem. & Metallurgical Eng., vol. 20, no. 6, March 15, 1919, pp. 271-273, 2 figs. Discussion of causes of this defect in high-grade alloy steels.

India

The Heavy Steel Industry in India. Andrew McWilliam. Indian & Eastern Engr., vol. 44, no. 1, Jan. 1919, pp. 14a-14b. Account of historical and technical side. (To be continued.)

Molybdenum Steel

Molybdenum Steel versus Gun-Erosion. Masatosi Okôchi, Masaichi Majima and Naoshi Sato. Jl. Soc. Mech. Engrs., Tokyo, vol. 22, no. 54, Nov. 1918, pp. 1-44, 50 figs. Experimental work to determine the resisting power of molybdenum steel against erosion. Investigation was conducted because of a report in which it was stated that steel containing three to four per cent. molybdenum was employed as gun material in the German artillery. Writers found no trace in chemical analyses of specimens taken from captured German guns.

Open Hearth

Water Cooled Equipment for Open Hearths. William C. Coffin. Blast Furnace & Steel Plant, vol. 7, no. 4, Apr. 1919, pp. 188-192 and 197, 6 figs. Equipment for preventing distortion of framework and maintaining economy of refractories. Paper read before Am. Inst. Min. Engrs.

Refractories

See Refractories, under MECHANICAL ENGINEERING.

Rolling Mills

See Mechanical Processes (Rolling Mills), under MECHANICAL ENGINEERING.

Smelting

A New Method for the Smelting of Iron Ores. Jas. W. Moffat. Canadian Min. Jl., vol. 40, no. 13, Apr. 2, 1919, pp. 207-210. Process designed for treatment of Canadian ores.

Tool Steel

The Evolution of a High Speed Tool Steel—II. T. L. Thorne. Am. Drop Forger, vol. 5, no. 3, Mar. 1919, pp. 146-149. Discussion on effects of various elements; methods of handling material when received in during production outlined; selection of furnaces important when treating finished tools.

Trumbull Steel Co. Plant

Valley Plant Produces Own Steel. Iron Trade Rev., vol. 64, no. 10, Mar. 6, 1919, pp. 641-645, 8 figs. General layout of Trumbull Steel Co.'s steel plant which includes seven 100-ton stationary open-hearth furnaces, a 36-in. blooming mill and an 18- and 21-in. bar mill.

Turbine Furnace

The "Turbine" Furnace. Iron & Coal Trades Rev., vol. 48, no. 2658, Feb. 7, 1919, p. 164, 1 fig. Aim is to insure a passage of air which shall be equal over every portion of the grate area. Air enters through five troughs which extend over whole length.

Zirconium Steels

Zirconium Steels (Les aciers au zirconium). Bulletin de la Société d' Encouragement pour l'Industrie Nationale, vol. 131, no. 1, Jan-Feb. 1919, pp. 149-155. English patent in regard to uses of zirconium in metallurgy; other practices in various metallurgical works.

VARIA

Bureau of Standards

Metallurgical Work of Bureau of Standards—II. G. K. Burgess. Blast Furnace & Steel Plant, vol. 7, no. 4, Apr. 1919, pp. 195-197. Review of research work concerning welding, tin conservation, bearing metals, protective metallic coatings, sand investigations, etc.

Diseases of Metals

Decomposition of Metals—I. A. I. Krynitzky. Chem. & Metallurgical Eng., vol. 20, no. 6, March 15, 1919, pp. 277-282, 11 figs. Review of various theories which have been advanced to explain so-called "disease of metal."

FERROALLOYS

Manufacture

The Manufacture of Ferro-Alloys—II. Robert M. Keeney. Automotive Eng., vol. 4, no. 3, Mar. 1919, pp. 121-124. Ores and furnaces used and methods followed to produce ferrochrome, ferromanganese, ferromolybdenum, ferrotungsten, ferrovanadium and ferrouranium.

Testing

Metallurgy and Motor Engineering. J. B. Hoblyn. Auto, vol. 24, no. 949, Mar. 13, 1919, pp. 256-257, 9 figs. Notes on the metallurgical examination and treatment to which materials are submitted in the technical laboratory of Vauxhall Motors, Ltd.

NON-FERROUS ALLOYS

Aluminum and Copper Alloys

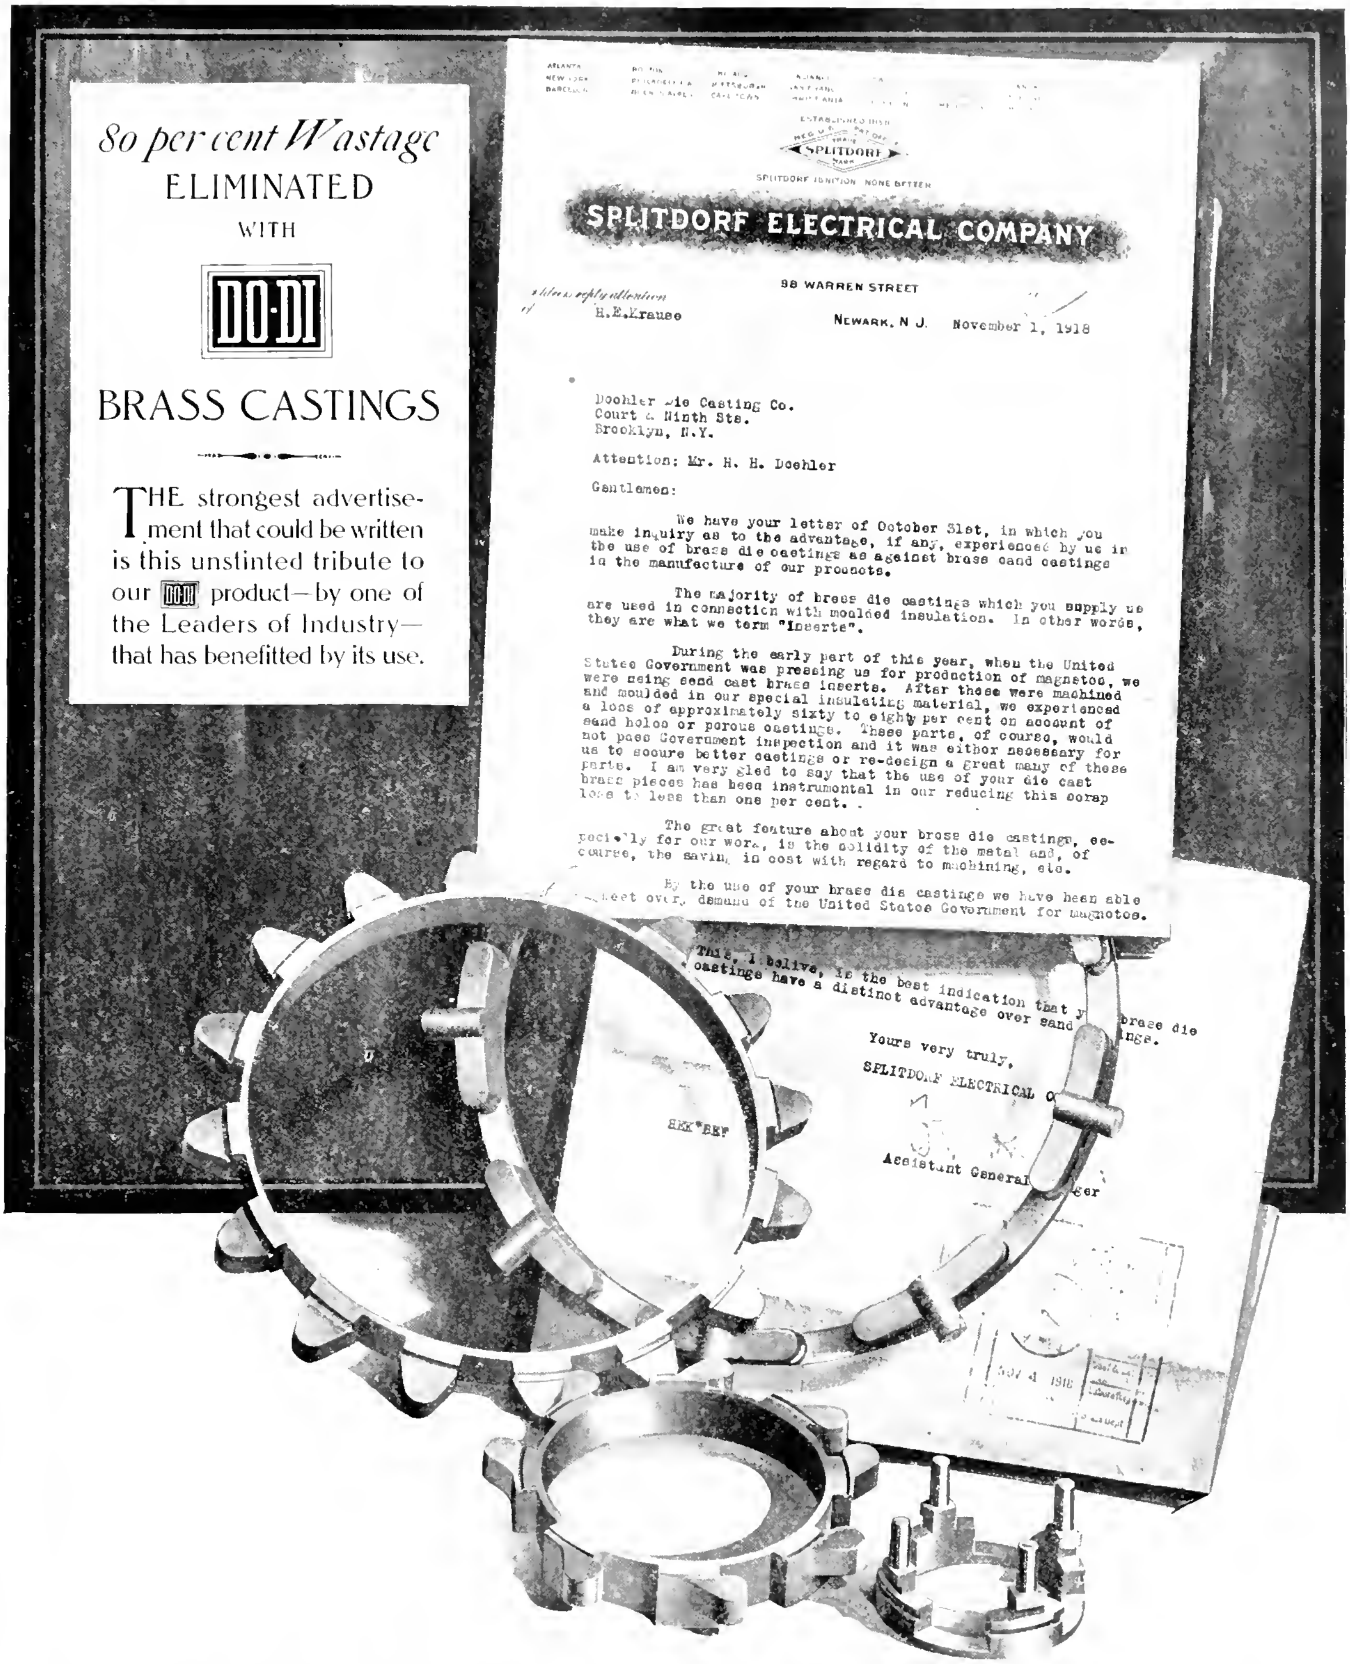
Aluminum and Copper Alloys. Machinery, vol. 13, no. 337, Mar. 13, 1919, pp. 656-659, 2 figs. Field for these alloys and difficulties met with in their manufacture.

Copper Alloys of High Tenacity

Copper Alloys of High Tenacity. O. F. Hudson. Metal Industry, vol. 14, no. 9, Feb. 28, 1919, pp. 163-166. Notes on strength of brasses and methods used to obtain brasses having high tensile strength. Paper before Birmingham Metallurgical Soc.

80 per cent Wastage
ELIMINATED
WITH
DO-DI
BRASS CASTINGS

THE strongest advertisement that could be written is this unstinted tribute to our DO-DI product—by one of the Leaders of Industry—that has benefitted by its use.



DOEHLER DIE-CASTING CO.

MAIN OFFICE AND EASTERN PLANT
BROOKLYN, N.Y.

WESTERN PLANT
TOLEDO, OHIO.

NEW JERSEY PLANT
NEWARK, N.J.

Aeronautics

AEROPLANE PARTS

Starters

The Liberty Starter for Aircraft Engines. Aviation, vol. 6, no. 4, Mar. 15, 1919, pp. 221-222, 3 figs. and Automotive Industries, vol. 40, no. 14, Apr. 3, 1919, p. 739, 3 figs. Combines gear reduction for hand cranking with an electric starter with high reduction ratio. Principal features and details of parts.

The Bijur Electric Starter for Aero Engines. Aerial Age, vol. 8, no. 22, Feb. 10, 1919, p. 10, 6 figs. Its application to Liberty motor.

Struts

Dimensions of Steel Tube Struts, E. S. Bradfield. Aerial Age, vol. 9, no. 2, Mar. 24, 1919, p. 112, 3 figs. Charts for computing dimensions.

AEROSTATICS

Dirigibles

Airships for Commercial Purpose. Aeronautics, vol. 16, no. 277, Feb. 5, 1919, pp. 152-154. A comparison of heavier- and lighter-than-air machines, and how each type may be utilized.

England's Aerial Effort (L'effort aérien de l'Angleterre). Aérophile, vol. 27, nos. 1-2, Jan. 1-15, 1919, pp. 14-15, 3 figs. Dirigibles developed during war.

Mooring Gear

The Possibilities of Airship Transport Services. Flight, vol. 11, no. 9, Feb. 27, 1919, pp. 263-267, 2 figs. Vickers patent mooring gear for rigid airships. Concluded from p. 232.

Schilling Apparatus for Measuring Hydrogen

Utilization of Schilling Apparatus in Control of Industrial Hydrogen (Sur les conditions d'utilisation de l'appareil de Schilling, pour le contrôle de l'hydrogène industriele), F. Bourion and Ch. Courtois. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 4, Jan. 27, 1919, pp. 232-235. Reasons for preference given to Schilling apparatus over hydrogen balance, in the measure of hydrogen destined for airship service.

AIRCRAFT PRODUCTION

Liberty Engine Parts, Manufacture of

Making Liberty Airplane Motor Parts. Machy., vol 25, no. 7, Mar. 1919, pp. 636-641, 13 figs. Methods employed in machining cylinder inlet and exhaust elbows for the Liberty airplane motor at plant of Packard Motor Car Co.

Naval Aircraft Factory

The Naval Aircraft Factory, G. W. Smith. Jl. Worcester Polytechnic Inst., vol. 22, no. 2, Jan. 1919, pp. 91-103, 2 figs. Account of war studies which led to construction and organization of factory.

Trimming Aircraft Parts

Trimming Aircraft Parts, W. A. Ford. Machinery, vol. 13, no. 335, Feb. 27, 1919, pp. 597,598, 4 figs. Boring holes in metal to secure required degree of lightness.

APPLICATIONS

Aerial Photography

Broad Field for Commercial Aerial Photography, M. A. Kinney. Flying, vol. 8, no. 3, Apr. 1919, pp. 250-255, 7 figs. Outline of possibility in scientific research, commercial endeavor and police work.

Aerial Routes

First Steps in Organizing an Aerial Route, Holt Thomas. Aeronautics, vol. 16, no. 281, Mar. 5, 1919, pp. 248-249. Safety of Commercial Air Service.

Canada

The Development and Future of Aviation in Canada, M. R. Riddell. Jl. Eng. Inst. Can., vol. 2, no. 3, Mar. 1919, pp. 200-209, 9 figs. Aero 504-k; J N-4, C. 504-K. Visualization of peace development of aeroplane.

Commercial Possibilities of Lighter and Heavier Than Air Machines

Commercialization of Rigid Airplanes (L'utilisation commerciale des aéronefs rigides). Génie Civil, vol. 74, no. 9, Mar. 1, 1919, pp. 167-169. Comparison of services given by airplanes and zeppelins.

Forest-Patrol Work

Use of Aeroplanes for Forest Patrol Work. Aeronautics, vol. 16, no. 277, Feb. 5, 1919, p. 155. Outlines American scheme for using aeroplanes in forest patrol work.

Preparing for Commercial Flying

Preparing for Commercial and Pleasure Flying, Graham-White. Aeronautics, vol. 16, no. 280, Feb. 26, 1919, pp. 230-234, 2 figs. Forecast of developments and analysis of difficulties.

AUXILIARY SERVICE

Radio Surgical Service

Radio-Surgical Airplane (Avion radio-chirurgical), Foveau de Courmelles. Aérophile, vol. 27, nos. 1-2, Jan. 1-15, 1919, pp. 18-20, 3 figs. Fitted with radiographic and surgical laboratories and power plant which permits speed of 100 miles per hour. Named after designers "Aerochir Némirovski-Tilmant."

DESIGN

Ailerons

Some Points in Aeroplane Design, F. S. Barnwell. Flight, vol. 11, no. 533, Mar. 13, 1919, pp. 345-349, 2 figs. Investigation of controlling power of ailerons. (Concluded.)

Bristol Fighter Design

Some Points in Aeroplane Design, F. S. Barnwell. Aeronautics, vol. 16, no. 281, Mar. 5, 1919, pp. 260-261. Analysis of Bristol fighters. Paper before Royal Aeronautical Society.

Radiators

The Principles of Cooling of Airplane Engine Radiators, H. B. Irving. Automotive Industries, vol. 40, no. 14, Apr. 3, 1919, pp. 740-742. Law of heat transmission from a surface to a fluid flowing over the surface; hp. expended in overcoming head resistance of radiator.

Wing Spars and Stability

Some Points in Aeroplane Design, F. S. Barnwell. Flight, vol. 11, nos. 9 and 10, Feb. 27 and Mar. 6, 1919, pp. 275-280 and 310-313, 9 figs. Graphs and tables in reference to design of wing spars. Comparative data of tail plane required to give longitudinal stability to a monoplane, "square" biplane and "staggered" biplane. (To be concluded.)

DYNAMICS

Flattening Out from Glides

Flattening Out of Aeroplanes After Steep Glides, Genjiro Hamabe. Jl. Soc. Mech. Engrs., Tokyo, vol. 22, no. 54, Nov. 1918, pp. 45-96, 8 figs. Theoretical determination of time required to restore a machine from a steep glide and of the "wing loading" set up during this motion.

Torsional Loads in Fuselage

Torsional Loads in the Fuselage of an Aeroplane, A. J. Sutton Pippard. Engineering, vol. 107, no. 2772, Feb. 14, 1919, p. 195, 1 fig. Suggests method of calculation based on assumption that deformation of fuselage is due to stretch of panel bracing wires, bulkhead bracing wires being considered as inoperative.

ENGINES

Basse-Selve

The 200-hp. Basse-Selve Aero Engine. Flight, vol. 11, no. 10, Mar. 6, 1919, pp. 297-305, 25 figs. Report based on examination of engine taken from remains of a German Rumpler two-seater biplane. Issued by Technical Dept. (Aircraft Production) Ministry of Munitions.

Bugatti-King

The King-Bugatti Aviation Engine, G. Douglas Wardrop. Aerial Age, vol. 8, no. 22, Feb. 10, 1919, pp. 1074-1080, 32 figs. Engineering description. (To be continued.)

Design

The Design of Aeroplane Engines, John Wallace. Aeronautics, vol. 16, nos. 278, 280 and 281, Feb. 12, Feb. 26 and Mar. 5, 1919, pp. 174-177, 220-222, and 251-255, 25 figs. Piston design and construction; distribution of side thrust; piston lubrication; piston rings; gudgeon-pin bearing; connecting rods; big-end bolts; twin connecting rods; Anzani arrangement; Canton system. (Continuation of serial.)

Hall-Scott

A Marine "Liberty," George F. Crouch. Motor Boat, vol. 16, no. 5, March 10, 1919, pp. 17-20, 10 figs. Hall-Scott 4-cyl. and 6-cyl. airplane motors modified to suit marine conditions.

Mercedes

200 Hp. High Compression Mercedes Engine. Aeronautics, vol. 16, no. 279, Feb. 19, 1919, pp. 204-206, 7 figs. Report on running performance, based on examination and tests carried out at R. A. E. on engine taken from Fokker D7 biplane (G/2 B/14). Issued by Technical Dept. of Air Ministry.

German Machines

Thermal Machines. German Aviation Motors (Machines thermiques—les moteurs de l'aviation alemande), Ed. Marcotte. Technique Moderne, vol. 10, no. 12, Dec. 1918, pp. 544-553, 29 figs. The various types are examined in reference to weight per hp., compression space, service given, and details in which they differ from French motors. (Concluded.)

"Le Rhone"

The "Le Rhone" 110 H. P. Engine, G. Douglas Wadrop. Aerial Age, vol. 9, no. 3, Mar. 31, 1919, pp. 156-157 and 177, 6 figs. General data: diagrammatic sketches of oiling and ignition systems.

Liberty

Mechanical Details of the Liberty Engine—II. Automotive Eng., vol. 4, no. 3, Mar. 1919, pp. 117-120, 6 figs. Drawings and specifications of cast-iron cylinder forms for tank use and of steel cylinder type with sheet-metal water jackets for airplane power plants.

Thomas-Morse

The Thomas-Morse Model 8-90 Aero Engine. Aerial Age, vol. 8, no. 26, March 10, 1919, pp. 1348-1349, 2 figs. Characteristics of four-cycle eight-cylinder V-type engine.

Union

The 125 Hp. Union Aircraft Engine. Aviation, vol. 6, no. 4, Mar. 15, 1919, pp. 230-232, 3 figs. Engine is of vertical 6-cyl. water-cooled type with valves in head and develops its rated hp. at 1400 r.p.m. Total weight 485 lb.

INSTRUMENTS

Testing

Tests of Aeronautic Instruments, P. M. Heldt. Automotive Industries, vol. 11, no. 13, Mar. 27, 1919, pp. 691-692, 2 figs. Mercurial standards and vacuum control board used in aeronautic instrument test chamber of Bureau of Standards. (Sixth Article.)

MATERIALS OF CONSTRUCTION

Dope

Fabric and Dope, F. W. Aston. Aeronautics, vol. 16, no. 279, Feb. 19, 1919, pp. 208-209. Rapidity of deterioration at different times of the year; comparison of English and German dope; influence of atmosphere surrounding fibres; methods of protecting fabric from sunlight.

MILITARY AIRCRAFT

Aerial Tactics

Aerial Tactics and the Defense Against Airplanes (La tactique aérienne et la défense contre avions), Jean-Abel Lefranc. Aérophile, vol. 27, nos. 1-2, Jan. 1-15, 1919, pp. 6-9. Remarks on significance of air warfare, based on records of past war.

German War Aviation

Evolution of German Aviation During the War 1914-1918 (Evolution de l'aviation alemande pendant la guerre de 1914-1918). Aérophile, vol. 27, nos. 1-2, Jan. 1-15, 1919, pp. 12-13. Characteristics of reconnoitring planes, bombing and chasing machines, presented in chronological tables indicating time of their development.

Le Père Fighter

The American Built Le Père Fighter. Aeronautics, vol. 16, no. 278, Feb. 12, 1919, pp. 178-179, 4 figs. Dimensions and weights.

PLANES

Ansaldo

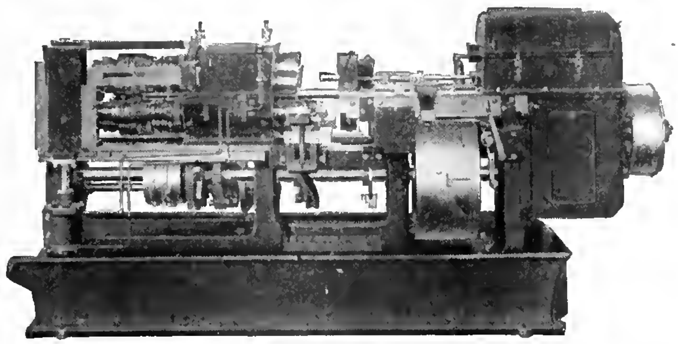
The Ansaldo Single and Two Seater Airplanes. Aviation, vol. 6, no. 4, Mar. 15, 1919, p. 223. Machine was designed with aim of including minimum head resistance and attaining maximum of efficiency. Italian type.

Bristol

Details of Bristol Aeroplane Types. Aeronautics, vol. 16, no. 280, Feb. 26, 1919, pp. 227-230, 6 figs. Fighter F.2B., with Rolls-Royce engine; triplane Braemer, with four Puma engines; fighter, single-seater scout, F, with Mercury engine; all-metal biplane, with Hispano-Suiza engine; and monoplane, M. 1. C., with Clerget engine.

Curtiss Triplane

The Curtiss Model 18-T Triplane. Aerial Age, vol. 9, no. 3, Mar. 31, 1919, pp. 154-155, 5 figs. General dimensions, areas, weights and performances.



F-W-L

F-W-L Navy Flying Boat—I, II, III. S. T. Williams. Automotive Industries, vol. 40, nos. 12, 13 & 14, Mar. 20 & 27, Apr. 3, 1919, pp. 634-637, 703-707 and 755-758, 25 figs. Twin-motored tractor biplane with total flying weight of 7 tons: cruising radius as a fighter, 10½ hours; normal crew four men. Details of hull construction; design and materials of various fittings; panel and strut layout. Details of engine mountings and fuel and oil tanks; gasoline supply system.

Handley-Page

The Handley-Page Type 0-400 Bomber. Aerial Age, vol. 8, no. 22, Feb. 10, 1919, pp. 1082-1083 and 1095, 4 figs. Dimensions, weights and equipment.

NC-1 Naval

The NC-1 Naval Flying Boat. Aerial Age, vol. 9, no. 2, Mar. 24, 1919, pp. 110-111, 5 figs. General dimensions, weights and performances; machine said to be one of largest ever built.

Packard

Packard's Commercial Sport-Type Plane. Motor Age, vol. 35, no. 10, Mar. 6, 1919, pp. 22-23, 4 figs., and Automotive Industries, vol. 40, no. 10, Mar. 6, 1919, pp. 531-534, 9 figs. Specifications of two-passenger biplane Packard company purposes to build and sell at $15,000. Line of three engines; plane designed to take eight-cylinder power plant. Calculated performance charts based on previous similar designs.

Pfalz

The Pfalz Single-Seater Fighting Aeroplane. Engineer, vol. 127, no. 3292, Jan. 31, 1919, pp. 95-97, 14 figs. Official record issued by the Aircraft Production (Technical) Department, Air Ministry.

Phoenix-Cork

Some Notes on the Phoenix-Cork Flying Boat. Aeronautics, vol. 16, no. 279, Feb. 19, 1919, p. 197, 1 fig., and Engineer, vol. 127, no. 3296, Feb. 28, 1919, pp. 194-196, 10 figs. Comparison with F3; performance during war; advantages claimed for this type are lesser weight and lower air resistance.

USD-9A

The USD-9A Airplane. Aviation, vol. 6, no. 4, Mar. 15, 1919, pp. 215-217, 6 figs. Data of machine, which is a two-seater tractor biplane.

Roland

Roland D VI Biplane (Le biplan Roland D VI). Aérophile, vol. 27, nos. 1-2, Jan. 1-15, 1919, pp. 10-11, 6 figs. Principal characteristics.

Siemens

The Siemens Type D IV Single-Seater Fighter. Flight, vol. 11, no. 53, Mar. 13, 1919, pp. 332-339, 14 figs. Elevations and plans; description of Siemens & Halske rotary engine in which cylinders and crankshaft rotate in opposite directions; record of climbing.

Touring

Peace Time Aeroplanes. Flight, vol. 11, no. 10, Mar. 6, 1919, pp. 323-324, 2 figs. Sketches of proposed side-by-side touring aeroplane.

RESEARCH

Altitude Engine Test Laboratory

The Altitude Engine Test Laboratory, P. M. Heldt. Automotive Industries, vol. 40, no. 10, Mar. 6, 1919, pp. 535-539, 8 figs. Installed for Advisory Committee of Bur. of Standards to make tests on aeroplane engines under conditions duplicating those met with when flying at high altitudes.

Atmospheric Conditions

Atmospheric Conditions affecting Power. A. Johnson. Aerial Age, vol. 9, no. 3, Mar. 31, 1919, pp. 166-167, 3 figs. Table showing density and pressure percentage at different heights and its use in calculation of engine power.

Tandem Planes

Experiments with Tandem Planes, Robert Gilbert Ecob. Sci. Am. Supp., vol. 87, no. 2256, Mar. 29, 1919, pp. 204-205, 3 figs. Langley tandem monoplane, Jeansen-Calliex tandem biplane, six-plane tandem models.

PROPELLERS

Graphs of Thrust and Horsepower

A Method of Approximating the Static Thrust and Brake Horse-Power of Air Propellers. W. Bernard Murphy. Aerial Age, vol. 9, no. 2, Mar. 24, 1919, pp. 114-115, 4 figs. Graphs of 2- and 4-bladed flat-faced sector screws.

TESTING

Radiators

Tests of Airplane Radiators, P. M. Heldt. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, pp. 479-483, 6 figs. Study by Bur. of Standards, bearing on head resistance, resistance to water flow and weight, all in relation to heat dissipated.

Rib Testing

Experimental Design and Testing of Airplane Ribs, George B. Fuller and Lessiter Milburn. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, pp. 456-460 and 489, 9 figs. Testing machine designed to distribute load as in flight.

Sand Testing

Sand Testing of Aeroplanes, Albert S. Heinrich. Aerial Age, vol. 9, no. 3, Mar. 31, 1919, pp. 158-160, 9 figs. Tests conducted at McCook Field on Victor advanced-training plane. (To be concluded.)

TRANSOCEANIC FLIGHT

Calculations

Civil Aerial Transport—Flying the Atlantic, G. Greenhill. Engineering, vol. 107, no. 2771, Feb. 7, 1919, p. 161. Calculations based on square sine law of Newton.

Transatlantic Route

A Proposed Aeroplane Route Across the Atlantic, William H. Hobbs. Flying, vol. 8, no. 3, Apr. 1919, p. 243, 1 fig. Via Newfoundland-Greenland-Iceland-Scotland.

Transoceanic Liners

Airships Practical for Commercial Use. Automotive Industries, vol. 40, no. 9, Feb. 27, 1919, pp. 461-463. Opinion is expressed that airships are valuable for transoceanic flight and that they can be supplemented by airplanes for short-haul work.

Possibilities of Airship Transport Services. Aeronautics, vol. 16, no. 279, Feb. 19, 1919, pp. 198-201, 5 figs. Scheme for service of transoceanic airship liners.

Marine Engineering

AUXILIARY MACHINERY

Compasses

The Navigational Magnetic Compass Considered as an Instrument of Precision, M. B. Field. Engineering, vol. 107, no. 2771, Feb. 7, 1919, pp. 187-192, 16 figs. Problem is studied from point of view of accepted theories concerning sources of error due to magnetic disturbances and the so-called permanent magnetism hammered into the ship in the course of building. Lecture before Inst. Elec. Engrs.

Evaporators

An Improved Method of Operating Evaporators, M. C. Stuart. Jl. Am. Sos. Naval Engrs., vol. 31, no. 1, Feb. 1919, pp. 63-96, 14 figs. Essential feature of method developed at U. S. Naval Eng. Experiment Station is production of fresh water at constant rate and in any desired amount within capacity of evaporator.

Luffing Cranes

4-Ton "Toplis" Luffing Cranes for Shipyards. Engineering, vol. 107, no 2772, Feb. 14, 1919, pp. 208-210, 4 figs. Example of application of this type of crane in a shipyard.

SHIPS

Boiler Mountings

Boiler Mountings, J. Purves. Mar. Engr. & Naval Architect, vol. 41, no. 498, Mar. 1919, pp. 193-195, 2 figs. Recent developments in marine-boiler-mounting design; suggestions for further safeguarding boiler. (To be continued.) Paper read before Liverpool Eng. Soc.

Cargo-Vessel Design

Speed, Dimensions and Form of Cargo Vessels, G. S. Baker and J. L. Kent. Engineering, vol. 107, no. 2775, Mar. 7, 1919, pp. 306-310, 4 figs. Economics of cargo ship propulsion so far as this is affected by speed and design of hull form; propulsive considerations in settling area of midship section; longitudinal distribution of displacement and type of level lines and body sections; notes on straight-frame ships, based upon test work carried out for British Government. Paper read before Instn. Engrs. & Shipbuilders in Scotland.

Cargo Vessels

Standard Sea-Going Cargo Vessel of 3,500-Tons Deadweight Built on the Lakes. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 206-207, 2 figs. Single-deck steamer of maximum Welland Canal size.

9,600-Ton Deadweight Cargo Vessel. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 200-203, 4 figs. Shelter-deck freighter designed by Federal Shipbuilding Co. for overseas trade; longitudinal framing adopted.

Specification for 4,300-Ton Steel, Screw, Cargo Steamships for Canadian Government Merchant Marine, Ltd. Can. Ry. & Mar. World, no. 253, March 1919, pp. 146-151, 5 figs. Dominion Government has ordered 45 steel screw cargo steamships aggregating 263,850 tons d. w. Of these 6 are to be according to specifications given in article.

"Robert Dollar" Type of Cargo Vessel. Int. Mar. Eng. vol. 24, no. 4, Apr. 1919, pp. 204-206, 2 figs. Designed by Skinner & Eddy Corporation, Seattle, Wash. to carry 8800 tons deadweight at sea speed of 11½ knots.

Concrete Ships

Economic Size of Concrete Ships, E. O. Williams. Engineering, vol. 107, no. 2772, Feb. 14, 1919, pp. 195-197, 1 fig. Writer discusses theory that disadvantage of weight of concrete ships compared with steel ships diminishes with increased size of vessels.

Stone Ships Cheaper than Steel. Mar. Rev., vol. 49, no. 4, Apr. 1919, pp. 190-191. Comparative costs of constructing and propelling concrete and steel tankers.

Diesel-Engined Motorships

American Diesel-Engined Motorship. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 208-211, 11 figs. Gear-reduction transmission applied to twin-screw wooden freighter equipped with high-speed Diesel engines.

Some Aspects of Large Diesel Cargo Ships, H. R. Setz. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 212-219, 6 figs. Steam and Diesel machinery installations compared.

Diesel Engines and the Merchant Marine. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 377-378. Review of developments on Pacific Coast.

Electric Propulsion

Marine Electric Propulsion. Mar. Engr. & Naval Architect, vol. 41, no. 498, Mar. 1919, pp. 182-184. Development of system and conclusions in regard to operation from records of practice. Paper before Students' Section Instn. Elec. Engrs.

U. S. S. "New Mexico," Henderson B. Gregory. Sci. Am., vol. 120, no. 14, Apr. 5, 1919 pp. 340-341, 4 figs. General arrangement of engines and motor rooms in electrically propelled battleship.

Fabricated Ship

"Fabricated" and "Standardized" Ships, N L. Van Tol. Am. Mar Engr., vol. 14, no. 3 Mar. 1919, pp. 5-6. Outstanding points o question.

Ferryboats

Military French-English Ferryboats (Le ferryboats militaires franco-anglais) P. (Génie Civil, vol. 74, no. 8, Feb. 22, 1919, p 141-146, 16 figs. Plans, dimensions and pa ticulars.

Geared Turbines, Double Reduction

Double-Reduction Geared Turbines for S. "Merida." Engineering, vol. 107, no. 277 Feb. 14, 1919, pp. 207-208, 2 figs. Vessel cargo steamer carrying 9100 tons on draft 25 ft.

Mark Boats

A Mark Boat That Will Mark, Frederi K. Lord. Motor Boating, vol. 23, no. 4, A 1919, pp. 17-19 and 68, 4 figs. How to bu a 10-ft. scow-type boat.

Norwegian Freighters

2400-Ton S. W. Norwegian Steamer. Shbuilding & Shipping Rec., vol. 13, no. 11, M 13, 1919, pp. 311-312, 6 figs. Details of S. Modemi, built and engined by Bergens Mek iske Vaerksted.

Oil Tankers

Oil Tank Steamer of 10,100 Tons D. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, 196-198, 2 figs. Type of vessel authorized Shipping Board: cargo space divided up i 18 main and 8 summer oil tanks.

Standard 7,500-Ton Oil Tanker. Int. M Eng., vol. 24, no. 4, Apr. 1919, pp. 198-19 2 figs. Single-screw vessel designed for 11 k sea speed.

Parallel Middle Body

Effect of Position of Parallel Middle B Shipbuilding & Shipping Rec., vol. 13, no. 11, Mar. 13, 1919, pp. 317-319, 4 figs. Variation of shaft horsepower, propeller revolutions and

propulsive coefficient with longitudinal position of parallel middle body in a single-screw cargo ship. Abstract of paper before Am. Soc. Naval Architects and Mar. Engrs.

Shaft Alignment

Optical Method of Shaft Alignment. William Norris. Jl. Am. Soc. Naval Engrs., vol. 31, no. 1, Feb. 1919, pp. 56-62, 7 figs. Report of realignment of inboard propeller shaft U. S. S. Mississippi.

Stresses in Ships

Stresses in Ships, Sydney V. James. Jl. Western Soc. Engrs., vol. 23, no. 5, May 1918, pp. 356-376, 8 figs. Discussion of methods for determining principal longitudinal stresses and statement of results of application of such methods to study of ships of well-known type.

Submarines

On the Equilibrium of a Submerged Submarine (Note sull' equilibrio dei sommergibili in immersione), C. de Feo V. Rivista Maritima, vol. 52, no. 1, Jan. 1919, pp. 63-92, 7 figs. Mechanical laws involved in process of submerging and diagrammatic study of systems of forces acting on submarine while submerging and when fuly submerged.

Troopship

Twin-Screw Troopship of 13,000 Tons D. W. Int. Mar. Eng., vol 24, no. 4, Apr. 1919, pp. 192-196, 5 figs. Three-deck combined passenger and cargo vessel of 20,900 tons displacement on draft of 31 ft. 9 in.

Vibrationless Boats

A Vibrationless Cruiser. Motor Boating, vol. 23, no. 4, Apr. 1919, p. 20, 3 figs. Designed to travel at 24 miles per hour with tremble eliminated at 20-mile speed, and to go 500 miles without replenishing fuel.

YARDS

Alabama Dry Dock Co.

A Southern Shipbuilding and Repair Plant. G. F. S. Mann. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 251-255, 11 figs. Methods employed in yards of Alabama Dry Dock & Shipbuilding Co.

Australia

Australian Shipbuilding. Commonwealth Engr., vol. 6, no. 6, Jan. 1, 1919, pp. 187-190, 5 figs. Shipbuilding at Government dockyards, Walsh Island, N. S. W.

Carolina Shipbuilding Corporation

Carolina Shipbuilding Corporation. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 240-245, 7 figs. Yard erected for building Emergency Fleet vessels. Contract calls for twelve 9,600-ton cargo ships.

Concrete Shipbuilidng in England

Concrete Shipbuilding Work in England. Concrete Age, vol. 29, no. 4, Jan 1919, pp. 12-15. Account of shipyards on South Coast, where eighteen concrete vessels are in course of construction. From Times Eng. Supp.

Concrete-Vessel Building

Shipping and Shipbuilding. Indus. Australian & Min. Standard, vol. 61, no. 1580, Feb. 20, 1919, p. 323. Construction of concrete vessels. Developments in the United Kingdom.

Delaware Wooden Shipyard

Large Wooden Shipyard on the Delaware. R. R. Shafter. Int. Mar. Eng., vol. 24, no. 4. Apr. 1919. pp. 256-259, 7 figs. Shipbuilding corporation organized to build wooden ships for Emergency Fleet.

Federal Shipbuilding Co.

Yard of the Federal Shipbuilding Company. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 266-270, 10 figs. Steel shipyard with twelve launching ways built by subsidiary of U. S. Steel Corporation.

Ford Methods

Ford Methods in Ship Manufacture, Fred E. Rogers. Indus. Management, vol. 57, no. 4, Apr. 1919, pp. 289-295, 12 figs. Subassembling and unit erecting. (Continuation of serial.)

Foundation Co., New Orleans

Foundation Company's New Orleans Yard. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 237-239, 2 figs. General arrangement of yard.

Great Lakes Shipyards

The Great Lakes Engineering Works. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 281-288, 14 figs. Details of shipyards and engine-building plant.

Groton Iron Works

Groton Iron Works Shipbuilding Plant. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 247-250, 10 figs. Layout, construction of shipyard and methods for handling material.

Launching

Tides, Terrain and Temper Play Important Parts in Launcaing. Motor Boating, vol. 23, no. 4, Apr. 1919, pp. 28-29, 4 figs. How a small crew can easily and safely launch a heavy cruiser of moderate size.

Manitowoc Shipbuilding Co.

Manitowoc Shipbuilding Company. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 271-280, 19 figs. Increase of steel shipyards on Great Lakes to meet demands of sea-going tonnage.

Merchant Shipbuilding Corporation, Bristol

Fabricated Ship Construction at Bristol Yard. Eng. News Rec., vol. 82, no. 12, Mar. 20, 1919, pp. 557-561, 8 figs. General plan and layout of plate-and-angle shop of Merchant Shipbuilding Corp.

Milwaukee

New Shipbuilding Enterprise in Milwaukee, Arthur F. Johnson. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 262-265, 6 figs. Yard for construction of steel and concrete vessels.

Naval Engineering

The Achievements of Naval Engineering in this War. William L. Cathcart. Jl. Am. Soc. Naval Engrs., vol. 31, no. 1, Feb. 1919, pp. 1-45, 19 figs. Achievements of Bur. Steam Eng. during the war. Address at Annual Meeting of Am. Soc. Mech. Engrs., Dec. 1918.

New Orleans Canal

Shipyard on New Orleans Canal for Building "Unsinkables." Eng. News Rec., vol. 82, no. 9, Feb. 27, 1919, pp. 434-438, 6 figs. Plan and details. The unsinkable ships being built are of the Le Parmentier (French) type.

Newburgh Shipyard

Construction of the Newburgh Shipyard. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 231-236, 7 figs. Description of shipyards and of accomplishments during past year.

See also MECHANICAL ENGINEERING, Heat-Treating (Engine Parts).

TERMINALS

French Ports

French Ports and the War (Les ports francais et la guerre). Génie Civil, vol. 74, nos. 4 & 9, Jan. 25 and Mar. 1, 1919, pp. 73-74 and pp. 161-167, 6 figs. Organization of transport of coal across France to Italy. Description of Calais and Boulogne and notes on the traffic of these ports before and during the war.

New York-New Jersey Port

United Port of New York and New Jersey, Hjalmar E. Skougor. Freight Handling & Terminal Eng., vol. 5, no. 3, Mar. 1919, pp. 89-92. Recommends that States of New York and New Jersey be consolidated to form one state or that all such parts of these states as are immediately affected by comprehensive plan for port development be joined together to form either a separate state or a federalized district similar to the District of Columbia. Paper presented before Soc. Terminal Engrs.

Industrial Technology

Abrasives

Electrothermic Abrasives (Les abrasifs electrothermiques), Jean Escard. Revue Générale de l'Electricité, vol. 5, no. 5, Feb. 1, 1919, pp. 180-190, 5 figs. Origin, manufacture; properties, and uses.

Acetylene

Acetylene and Its Generation. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, p. 75. Risk of explosion; effect of impurities in carbide.

Ammonia

The Synthesis of Ammonia at High Temperatures—III, Edward Bradford Maxted. Jl. Chem. Soc., vols. 115 and 116, no. 676, Feb. 1919, pp. 113-119, 1 fig. Formation of ammonia in single-phase, 50 cycle, 375-volt arc.

Ammonium Nitrate

The United States Ammonium Nitrate Plant, Perryville, Md. Chem. & Metallurgical Eng., vol. 20, no. 7, Apr. 1, 1919, pp. 320-326, 8 figs. Description of manufacture of ammonium nitrate by the double decomposition of Chilean saltpeter and ammonium sulphate; phases, their control and application; plant operations.

Antimony Salts

Antimony in the Textile Industry, E. R. Darling. Textile World Jl., vol. 55, no. 13, Mar. 29, 1919, pp. 31, 33 and 35. Values of the various salts in printing and dyeing.

Benzol

Benzol Recovery. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, p. 72. Problem of distribution form gas works; cost of recovery.

Benzol and Phenols

Separation of Benzol and Extraction of Phenols in Gas Works of Paris and Suburbs (Le débenzolage et l'extraction des phénols dans les usines à gaz de Paris et de la banlieue parisienne), L. Lindet. Bulletin de la Société d'Encouragement pour l'Industrie Nationale, vol. 131, no. 1, Jan.-Feb. 1919, pp. 133-137. Principle of Paul Mallet apparatus consists in washing gas in a liquid less volatile than the one it holds in suspension and distilling resulting mixture.

Carbides, Silicides and Borides

Metallic Carbides, Silicides and Borides (Les carbures, borures et siliciures métalliques), Jean Escard. Revue Générale de l'Electricité, vol. 5, no. 9, Mar. 1, 1919, pp. 339-351. Concerning their industrial utilization, notably in metallurgical and chemical arts.

Charcoal

Manufacture of Charcoal as an Economic Measure, Helge Sylven. Sci. Am. Supp., vol. 87, no. 2251, Feb. 22, 1919, pp. 124-126, 5 figs. Utilization of lumber-mill waste. From West Coast Lumberman.

Chlorine

Commercial Uses of Chlorine, V. B. Kokatnur. Gen. Meeting Am. Electrochem. Soc., Apr. 3-5, 1919, paper 10, pp. 141-155. Classification of direct and indirect ways of possible utilization of chlorine.

Electroplating

Lay-out and Cost of Electro-Plating Plant and Equipment. Metal Industry, vol. 14, no. 10, Mar. 7, 1919, pp. 186-187, 1 fig. Tentative plans prepared for electro-plating and metal-finishing companies.

Enamels

Enamels for Cast Iron, Homer F. Staley. Jl. Am. Ceramic Soc., vol. 1, no. 10, Oct. 1918, pp. 703-709. Tin enamel and antimony enamel compositions.

The Relative Action of Acids on Enamels—III, E. P. Poste. Jl. Am. Ceramic Soc., vol. 2, no. 1, Jan. 1919, pp. 32-43, 9 figs. Tests of acid resistance undertaken by Sub-Committee on Enamels of Committee on Standards of Am. Ceramic Soc. Reference is made to previous investigation.

Fertilizers

Fertilizers, B. de C. Marchand. South African Jl. Industries, vol. 1, no. 16, Dec. 1918, pp. 1521-1529, 1 fig. Attempt to ascertain quantity of fertilizer of all kinds manufactured in the Union of South Africa. Seventh and concluding article.

Galvanizing

The Electro-Galvanising of Booster Cases, Adapters and Detonator Fuse Components, T. C. Eichstaedt. Metal Industry, vol. 14, no. 10, Mar. 7, 1919, pp. 181-182. Method developed by writer.

Modern Processes of Galvanizing Sheet Steel (Procédés modernes de galvanisation des tôles d'acier), Métallurgie, vol. 51, nos. 4, 5, 6, 8, 10 and 11, Jan. 22 and 29, Feb. 5 and 19, Mar. 5 and 12, 1919, pp. 173-174, 224-225, 279-280, 396, 520, 582-583; 1 fig. Tanks, baths, and manipulation: cleaning and scraping; losses; scheme showing arrangement of apparatus; relative cost of various processes; galvanizing tanks; operation of tanks. (Concluded.) From Iron Age.

Gas Industry

Medium Pressure, A. C. Howard. Gas Indus., vol. 19, no. 2, Feb. 1919, pp. 46-48. Distribution of booster system of Citizens Gas & Fuel Co. of Terre Haute.

Springfield Tests Indicate That Retort Life Is Increased by Steaming. Am. Gas Eng. Jl., vol. 110, no. 10, Mar. 8, 1919, pp. 211-213. Tests were made in connection with investigation by Mass. Board of Gas & Elec. Commission relative to adoption of calorific standard for gas.

Standard Gas. Engineering, vol. 107, no. 2775, Mar. 7, 1919, pp. 304-306, 3 figs. Tests performed and conclusions arrived at by Research Sub-Committee of Instn. Gas. Engrs.

Unusual Carbonizing Methods, James A. Brown. Gs. Jl., vol. 145, no. 2904, Jan. 7, 1919, p. 28. Difficulties encountered in operation of inclined ovens at Flint and Evansville, Mich. Paper before Mich. Gas Assn.

A ROW OF MOULDING MACHINES
If you could go through our plant and see the character and completeness of our facilities, you would instantly recognize why we can undersell and outpoint any of the ordinary methods of producing bronze bushings.

The reason we are large producers of bushings

In ever increasing numbers, manufacturers are coming to us for bushings because our selling prices are less than their cost of manufacture.

Because, through specializing, we have succeeded in producing longer wearing and more accurate bushings.

Because, by careful business management and volume operations, we meet any reasonable production time requirement. Practically every bushing user, to the extent of fifty bushings of a kind and over, benefits by our service.

We want you to test that last statement. Ask for quotations

The Bunting Brass & Bronze Co.
729 Spencer Street, Toledo, Ohio

BUNTING
BRONZE BUSHINGS AND BEARINGS
PATENTED

Principles of Gas Purification and Purifier Design, F. W. Steere. Gas Age, vol. 43, no. 6, Mar. 15, 1919, pp. 285-290, 8 figs. Regarding improvements in apparatus employed in removing sulphur from gas. (Continuation of serial.)

Gasoline

Gasoline from Natural Gas, G. A. Burrell. Petroleum Age, vol. 6, no. 3, March 1919, pp. 101-104. Types of plants; points concerning operation.

Greenstreet Cracking Plant, R. H. Kinnear. Petroleum Age, vol. 6, no. 3, March 1919, pp. 76-78, 5 figs. Details of method for making gasoline by cracking petroleum fractions.

Status of Refinery Practice with Regard to Gasoline Production, E. W. Dean. Automotive Eng., vol. 4, no. 3, Mar. 1919, pp. 114-115. Bureau of Mines suggestions in regard to increasing output of gasoline from a given quantity of crude oil.

Properties of Motor Gasoline—II, E. W. Dean. Automotive Eng., vol. 4, no. 3, Mar. 1919, pp. 132-134 and 147. Laboratory methods of testing gasoline and suggested specifications for motor gasoline.

Glass

Welding Glass (Notes sur le soudage des verres), Léon Appert. Bulletin de la Société d'Encouragement pour l'Industrie Nationale, vol. 131, no. 1, Jan.-Feb. 1919, pp. 67-91, 4 figs. History of operation; study of physical characteristics required and of phenomena taking place; classification and description of processes.

The Detection of "Ghosts" in Prisms, T. Smith. Sci. Am. Supp., vol. 87, nos. 2249 and 2245, Feb. 8 and 15, 1919, pp. 92-94 and 108-109, 20 figs. Method for developing optical prisms free from undesirable reflections. From Tran. Optical Soc. Lond.

Glues

Properties and Preparation of Glues. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 382-386. Data on properties, preparation, classification, grading and testing of glues, strength of glued joints, etc., based on experimental work of Bureau of Aircraft Production.

Helium

Helium in Natural Gas, G. A. Burrell. Natural Gas & Gasoline Jl., vol. 13, no. 3, Mar. 1919, pp. 97-98. How helium is extracted for use in balloons and dirigibles.

Hydrogen

Hydrogen from Ferrosilicon. Iron Age, vol. 103, no. 10, Mar. 6, 1919, p. 608. French process for filling British dirigible balloons.

Lead Salts

The Sub-Acetate and Sub-Sulphate of Lead, Henry George Denham. Jl. Chem. Soc., vols. 115 and 116, no. 676, Feb. 1919, pp. 109-113. Lead sub-acetate obtained by action of acetic anhydride on lead sub-oxide at 195 deg. cent.; physical and chemical properties of substance.

Linoleum

History and Manufacture of Floor-Cloth and Linoleum, M. W. Jones. Jl. Soc. Chem. Indus., vol. 38, no. 3, Feb. 15, 1919, pp. 26T-31T. Account of development of industry in British Empire.

Mustard Gas

Continuous Vacuum Still for "Mustard Gas," Elford D. Streeter. Jl. Indus. & Eng. Chemistry, vol. 11, no. 4, Apr. 1, 1919, pp. 292-294, 1 fig. Apparatus constructed for continuous distillation of "mustard gas."

Development of Mustard Gas. Jl. Indus. & Eng. Chemistry, vol. 11, no. 4, Apr. 1, 1919, pp. 287-291, 3 figs. Commercial production of ethylene apparatus and plant procedure for absorption of ethylene gas and monochloride. Purification of product.

Nitric Acid

Concentration of Nitric Acid (La concentration de l'acide nitrique), M. Kaltenbach. Chimie & Industrie, vol. 2, no. 2, Feb. 1, 1919, pp. 142-152, 6 figs. Theoretical conditions; scheme of apparatus.

Nitrogen Fixation

The Present Status of Nitrogen Fixation, Alfred H. White. Jl. Indus. & Eng. Chem., vol. 11, no. 3, Mar. 1, 1919, pp. 231-237, 3 figs. Summary of processes.

Odors

An Investigation of Stenches and Odors for Industrial Purposes, V. C. Allison and S. H. Katz. Jl. Indus. & Eng. Chemistry, vol. 11, no. 4, Apr. 1, 1919, pp. 336-339, 3 figs. Apparatus and procedure. Paper read before Am. Chem. Soc.

Organic Chemistry

Future of Industrial Organic Chemistry, Harold Hibbert. Chem. & Metallurgical Eng., vol. 20, no. 7, Apr. 1, 1919, pp. 335-341, 2 figs. Review of industries depending on organic chemical development, such as food, clothing, fuel, drugs and arts.

Photography

A Wax Medium and Process for the Permanent Coloring of Photographs, A. Vernon Godbold. Sci. Am. Supp., vol. 87, no. 2248, Feb. 1, 1919, pp. 74-75. From British Jl. Photography.

The Yellowing of Paper, Alfred B. Hitchins. Sci. Am. Supp., vol. 87, no. 2257, Apr. 5, 1919, p. 222, 3 figs. Study of causes of principal factors producing deterioration. Contribution to Paper from Ansco Research Laboratory.

Pickling

Some experiments with Substitutes for Sulphuric Acid for Pickling, E. S. Thompson. Brass World, vol. 15, no. 3, Mar. 1919, pp. 79-80. Comparative tests on niter cake and sulphuric acid to determine their relative values as pickling agents on hot-rolled flange steel.

Porcelain

Note on Certain Characteristics of Porcelain, A. V. Bleininger. Jl. Am. Ceramic Soc., vol. 1, no. 10, Oct. 1918, pp. 697-702, 1 fig. Tests at Pittsburgh laboratory of Bur. of Standards.

Soap and Candles

The Manufacture of Soap and Candles, M. Rindl. South African Jl. Industries, vol. 1, no. 16, Dec. 1918, pp. 1487-1495. Raw materials and by-products of industry; development and present condition in South Africa.

Sulphuric Acid

Manufacture of Sulphuric Acid by the Chamber Process, George Crisp. Gas. Jl., vol. 145, no. 2907, Jan. 28, 1919, pp. 173-175. Outline of various operations in plant and chemical reactions in chambers. Paper before Midland Section of Coke Oven Managers' Assn.

Tar, Dehydration of

Dehydration of Various Tars, W. A. Twine. Gas Jl., vol. 145, no. 2912, Mar. 4, 1919, pp. 462-464, 2 figs. Operation of Mond gas-pitch plant and of dehydrating plant for carbureted water-gas emulsion. Paper read before Midland Junior Gas Assn.

Trinitrotoluene Residues

Trinitrotoluene Residues and Their Utilisation, Maurice Copisarow. Chem. News, vol. 118, no. 3065, Jan. 10, 1919, pp. 13-14. Derivation of iso-trolyte, liquid T.N.T., chloropicrin and sulphide dyes.

Water Gas

Operation and Chemical Control of Water Gas Sets in Small Plants, H. Vittinghoff. Am. Gas Eng. Jl., vol. 110, no. 8, Feb. 22, 1919, pp. 163-164. Concerning economical operation.

Operating a Water Gas Set Without a Relief Holder in Parallel with By-Product Coke Ovens, A. H. Harris. Am. Gas Eng. Jl., vol. 110, no. 9, Mar. 1, 1919, pp. 185-188, 5 figs. General layout of plant.

All-New Water Gas Plant Results at Providence, Wm. Russell. Gas Age, vol. 43, nos. 6 and 7, Mar. 15 and Apr. 1, 1919, pp. 277-282 and 364-366, 8 figs. Buildings consist of generator house, engine and pump house, washer house and purifying house. (To be continued.) Before N. E. Assn. Gas Engrs.

Railroad Engineering

BRAKES

Brake Tests

Report on the Automatic Straight Air Brake. Ry. Age, vol. 66, no. 13, Mar. 28, 1919, pp. 840-842. Tests of air-brake system of Automatic Straight Air Brake Co. of N. Y., conducted by Bureau of Safety.

ELECTRIC RAILROADS

Financial Condition

Electric Railways and Investors, Francis H. Sisson. Elec. Ry. Jl., vol. 53, no. 11, Mar. 15, 1919, pp. 506-608. Discusses financial condition of electric railways, which in writer's opinion is serious and has been aggravated by large wage awards. Paper before Am. Elec. Ry. Assn.

Narrow-Gage Railways

The Electric Railway of 0.60 m. Gage (Le chemin de fer électrique à écartement de 0.60m.), L. Esbran. Bulletin de la Société Française des Electriciens, vol. 9, no. 76, Jan. 1919, pp. 53-71, 4 figs. Steam locomotives vs. electric locomotives for 24-in. gage roads; transmission of power; construction of track.

High Power Electric Locomotives for Narrow Gauge Goods Trains. Elecn., vol. 82, no. 2128, Feb. 28, 1919, pp. 250-252, 5 figs. Comparison of various electrical locomotives. (Concluded.)

Single-Phase Locomotive, Swiss

The Single-Phase Locomotives of the Swiss Federal Railways and the New Oerlikon Locomotives (Las locomotoras monofásicas de los ferrocarriles federales suizos y nuevos tipos de locomotoras de los talleres de construccion Oerlikon). Energia Eléctrica, vol. 21, no. 2, Jan. 25, 1919, pp. 21-23, 2 figs. General features and dimensions of types—I-C-I and I-BB-I. (To be continued.)

ELECTRIFICATION

American

Some Possibilities of Steam Railroad Electrification, Calvert Townley. Elec. Rev., vol. 74, no. 12, Mar. 21, 1919, pp. 452-454. Plea for greater coöperation between railroad and electrical interests.

French

Partial Electrification of a Great Railway System (L'électrification partielle d'un grand réseau de chemins de fer), Revue Générale de l'Electricité, vol. 5, no. 11, Mar. 15, 1919, pp. 422-427, 4 figs. Economic considerations involved in electrification project of Cie. d'Orleans. Supplements article in issue of Nov. 16, 1918, p. 730. Paper before Société d'Encouragement pour l'Industrie Nationale.

EQUIPMENT

Dynamometer Car

Old and New Dynamometer Cars, London & North-Western Railway. Ry. Gaz., vol. 30, no. 8, Feb. 21, 1919, pp. 304-305, 4 figs. Mechanism consists of laminated spring having 30 flat plates, each separated from next by rollers; a cast-iron bracket is bolted on the spring and moves with it, so actuating traction pen, which registers amount of pull in tons on paper record.

Motor Inspection Cars

A New Rail Motor Inspection Car. Railway Gaz., vol. 30, no. 11, Mar. 14, 1919, pp. 489-490, 1 fig. Report of tests of Midland Railway Co.

LABOR

British

The Personnel of the Railway Engineer's Department Under State Control. Ry. Gaz., vol. 30, no. 7, Feb. 14, 1919, pp. 249-250. Writer, who claims 20 years' railroad experience, takes gloomy view of British railway nationalization.

LOCOMOTIVES

Adhesion

Locomotive Adhesion, H. C. Webster. Ry. Gaz., vol. 30, no. 10, Mar. 7, 1919, pp. 447-449, 2 figs. Analysis of variation in pressure between tire and rail; graph showing resistance to slipping per wheel against coefficient of friction.

Australian Locomotives

Australian Railways. Indus. Australian & Min. Standard, vol. 61, no. 1581, Feb. 27, 1919, p. 375, 2 figs. Australian types of locomotives.

Balancing

Balancing of Locomotives, S. H. Jenkinson. New Zealand Jl. Sci. & Technology, vol. 2, no. 1, Jan. 1919, pp. 19-28, 2 figs. Equations for balancing for various defined positions of balance wheels.

Consolidation

Large Consolidation Type Locomotive for the P. & R. Ry. Age, no. 12, Mar. 21, 1919, pp. 760-762, 2 figs. With tractive effort of 61,260 lb. and small drivers, they are adapted to heavy drag service.

Electric Locomotives

See Electric Railroads, above.

Powdered Fuel

Powdered Fuel Burning Apparatus for an Australian Railway. Ry. Rev., vol. 64, no. 12, Mar. 22, 1919, pp. 457-459, 4 figs. Details of 50-ton, 6-wheel switching locomotive operating on powdered fuel with Fuller engineering equipment.

Standard Heavy 2-10-2

Standard Heavy 2-10-2 Locomotive. Ry. Mech. Engr., vol. 93, no. 3, March 1919, pp. 119-123, 14 figs. Plans, sections and dimensions of heaviest Administration single-unit type.

Heavy Type Locomotive for Rock Island. Ry. Jl., vol. 25, no. 4, Apr. 1919, pp. 17-18, 2 figs. Details of 2-10-2 type, designed for load of 60,000 lb. on each pair of drivers and said to be capable of traversing 16-deg. curves.

MAINTENANCE

Car Inspection

Unified Inspection and Maintenance of Car Equipment, J. J. Tatum. Ry. Rev., vol. 64, no. 13, Mar. 29, 1919, pp. 473-474. Explanation of purposes of railroad administration in its efforts to standardize railway rolling stock and in establishment of uniform rules for maintenance of already existing equipment. Also in Ry. Age, no. 12, Mar. 21, 1919, pp. 773-775.

Labor-Saving Devices

30 Labor-Saving Devices or "Kinks" for Railway Maintenance of Way Work. Eng. & Contracting, vol. 51, no. 12, Mar. 19, 1919, pp. 288-290. Report of Committee on Labor-Saving Devices at convention of Am. Ry. Eng. Assn.

OPERATION AND MANAGEMENT

Freight Handling

Reducing the Cost of Handling Freight. Ry. Rev., vol. 64, no. 12, Mar. 22, 1919, pp. 453-454. 4 figs. Operation of N. Y. Central freight terminal in Cleveland.

Loading, Train and Engine

Train and Engine Loading, T. H. Williams. Proc. Pacific Ry. Club, vol. 2, no. 11, Feb. 1919, pp. 3-15 and (discussion) pp. 16-23. Definition and explanation of terms used in connection with train and engine loading.

Maximum Car Loading, Wm. H. McClymonds. Ry. Rev., vol. 64, no. 13, Mar. 29, 1919, pp. 474-475. Discusses advisability of keeping freight-car loads up to the maximum possible and consistent in the circumstances. Paper read before Pacific Ry. Club.

Railroad Problem

Compensation of Railroads Under Federal Control, J. M. Souby. Ry. Age, no. 12, Mar. 21, 1919, pp. 751-754. Writer believes that less than justice has been done by Administration in its interpretation of the law taking over the roads.

A Possible Solution of the Railroad Problem—II, F. J. Lisman. Ry. Age, vol. 64, no. 14, Apr. 4, 1919, pp. 883-889, 3 figs. Maps showing tentative combination of railway systems, indicating possibilities of combining strong and weak systems so that strong will easily be able to carry weak.

San Francisco

New Facilities to Eliminate Congestion in San Francisco, C. W. Geiger. Elec. Traction, vol. 15, no. 3, Mar. 15, 1919, pp. 177-180, 4 figs. Construction of extra tracks for relieving congestion at terminals of United RR. of San Francisco.

PERMANENT WAY AND BUILDINGS

Pearson's Permanent Way

Pearson's Patent Permanent Way, J. D. Pearson. Indian Eng., vol. 65, no. 7, Feb. 15, 1919, pp. 96-97, 7 figs. In principle it resembles longitudinal rail formerly used in 7-ft. gage. It provides continuous support for rail without use of transverse ties.

Rail Bonds

Conditions Govern the Choice of Rail Bonds, G. H. McKelway. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 591-592, 5 figs. Discussion of common types of rail bonds and their adaptation to conditions.

Surveys

Railway Right-of-Way Surveys and Descriptions, Ed. Thompson Wilkie. Can. Engr., vol. 26, no. 10, March 6, 1919, pp. 277-279, 1 fig. Suggests method of making right-of-way surveys. Presented at the Meeting of Assn. Ontario Land Surveyors.

Ties, Waterproofing

Waterproofing Railway Ties to Preserve Them, H. K. Wicksteed. Ry. Age, vol. 66, no. 13, Mar. 28, 1919, pp. 849-850. Method of treatment involves thorough drying and then sealing against moisture. Paper read before Can. Ry. Club.

RAILS

Conservation

Some Results of Rail Conservation, W. R. Dunham, Jr. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 562-565, 7 figs. Aligning of old rails and elimination of low joints.

Creep

Rail Creep and Expansion, E. Capone. Tramway & Ry. World, vol. 45, no. 13, Mar. 13, 1919, pp. 115-117, 8 figs. Anchors for conductor rails. Method for anchoring sleepers.

Specifications

Change in Rail Specifications Proposed. Iron Age, vol. 103, no. 13, Mar. 27, 1919, p. 819. Results of experiments on gagging and testing rails. Presented at Convention Am. Ry. Eng. Assn.

See also MECHANICAL ENGINEERING, Welding (Rail Joints, Thermic Welding).

ROLLING STOCK

Automobile Cars

Automobile Cars for the I. C. Ry. Mech. Engr., vol. 93, no. 3, March 1919, pp. 141-145, 12 figs. Design features of single-sheathed type of 80,000 lb. capacity.

Concrete Cars

Concrete Freight Car. Ry. Jl., vol. 25, no. 4, Apr. 1919, p. 25. Gondola type built for Illinois Central R.R. Claimed that tests of completed cars, both empty and loaded, demonstrated its practicability for rough service.

Gondola Car of Reinforced-Concrete Construction. Ry. Age, no. 12, Mar. 21, 1919, pp. 776-778, 3 figs. Design incorporating steel center sills with concrete floor, sides and ends.

Concrete Freight Car. Ry. Rev., vol. 64, no. 13, Mar. 29, 1919, pp. 475-476, 3 figs. Description of gondola-type car in which the body structure has been made of reinforced concrete resting upon and amalgamated with a steel center sill and body bolster assembly of usual form.

Freight Equipment

Freight Equipment as Handled Under Present-Day Interchange, T. J. O'Donnell. Official Proc. Car Foremen's Assn. Chicago, vol. 14, no. 5, Feb. 1919, pp. 78-87. Conditions, from mechanical standpoint, which determine selection and movement of freight cars.

Lighting, Electric

Electric Lighting of Railway Cars, B. H. Ehringer. Official Proc. Car Foremen's Assn., Chicago, vol. 14, no. 5, Feb. 1919, pp. 29-33 and (discussion) pp. 33-35. Ball bearings vs. brass bearings in lighting equipment, from point of view of maintenance.

Workshop Trains

60. Cm. Workshop Trains for France. Ry. Gaz., vol. 30, no. 4, Jan. 24, 1919, pp. 135-137, 8 figs. Each train (narrow-gage road) comprises generating car, two machinery cars, tool van, stores van and officers' car. Generating car is fitted with gasoline-electric generator sets in duplicate.

SAFETY AND SIGNALING SYSTEMS

Tunnel Signals

An Automatic Audible Warning for Tunnels. Ry. Gaz., vol. 30, no. 4, Jan. 24, 1919, pp. 141-142, 1 fig. Tube slung throughout length of Metropolitan Ry. 2200-ft. tunnel is struck by hammers actuated by electro magnets which train sets in operation on entering.

SHOPS

Forge Work

Buckles for Laminated Springs and Other Forge Work. Ry. Gaz., vol. 30, no. 4, Jan. 24, 1919, pp. 142-144, 5 figs. Manufacturing operation in forge department of a railway shop.

Locomotive Driving Boxes

Machining Locomotive Driving Boxes, M. H. Williams. Ry. Mech. Engr., vol. 93, no. 3, March 1919, pp. 155-159, 8 figs. Appliances designed to obtain accuracy and reduce time.

Superheater Locomotives

Shop Treatment of Superheater Locomotives, A. D. Williams. Railroad Herald, vol. 23, no. 3, Feb. 1919, pp. 67-69. Practice of Southern Pacific in converting saturated locomotives to superheated. From paper before Pacific Coast Ry. Club.

Welding

Spot Welding Railroad Tinware. Ry. Mech. Engr., vol. 93, no. 3, March 1919, pp. 151-153, 3 figs. Equipment used by I. C.

See also MECHANICAL ENGINEERING, Welding (Frog Shop; Tires, Welded).

TERMINALS

Akron

Modern Terminal in Akron. Elec. Traction, vol. 15, no. 3, Mar. 15, 1919, pp. 167-169, 4 figs. Prominent feature in arrangement of train shed with separate subway entrances to boarding platforms located between each pair of tracks.

Cleveland

New Plan for a Union Station at Cleveland, Ohio. Ry. Age, no. 12, Mar. 21, 1919, pp. 755-758, 5 figs. Suggested design for passenger station with a two-level street entrance. Also in Ry. Rev., vol. 64, no. 13, Mar. 29, 1919, pp. 469-472, 6 figs.

Glasgow

North British Railway Improvements at Glasgow, Frederick C. Coleman. Ry. Age, vol. 66, no. 13, Mar. 28, 1919, pp. 843-846, 6 figs. Layout of freight yard and warehouses. Said to be largest terminal in Scotland.

STREET RAILWAYS

Fares

Rate of Return in Service-at-Cost Franchises, Edwin Gruhl. Elec. Ry. Jl., vol. 53, no. 11, Mar. 15, 1919, pp. 502-505. Remarks that while commissions and courts have not established basis for fixing rate of return necessary to attract capital, nevertheless position of company, basis of fair value and various safeguards, all influence investor's demand. Before Am. Elec. Ry. Assn.

How the Public Feels About It. Elec. Ry. Jl., vol. 53, no. 13, Mar. 29, 1919, pp. 639-643. Opinions of representative public leaders of various classes regarding guarantee of return, aid through taxation, municipal vs. state ownership, and indeterminate franchise.

Car Lighting

Urban Rapid Transit Car Lighting, Clifton W. Wilder and Albert E. Allen. Tran. Illum. Eng. Soc., vol. 14, no. 1, Feb. 10, 1919, pp. 24-35 and (discussion) pp. 36-44, 16 figs. Study of problem in New York City, undertaken by writers in behalf of Public Service Commission.

Freight Traffic

Development of Freight Traffic on Interurban Lines, A. B. Cole. Elec. News, vol. 28, no. 6, Mar. 15, 1919, pp. 29-30 and 40. Considered in its relations to the law, the public, shippers, electric-railway operators, the traffic bureau, service, rates and facilities.

Maintenance

Maintenance Problems, Arthur C. Carty. Elec. Traction, vol. 15, no. 3, Mar. 15, 1919, pp. 184-186, 4 figs. Account of endurance of tramway for traveling 750,000 miles in 22 years.

Maintenance Practice of the San Francisco Municipal Railway, N. A. Eckhart. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 559-561, 3 figs. Results of five years of operation with reference to relation of construction to upkeep.

Maintenance of Door Operators, George E. Oakley. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 588-589. Writer outlines methods used for operating and controlling movement of doors and describes general methods used in inspection and overhauling of door apparatus.

Traffic Check

The Traffic Check and What It Showed on the Public Service Railway. Elec. Ry. Jl., vol. 53, no. 13, Mar. 29, 1919, pp. 644-648, 2 figs. Origin to destination check of passenger traffic, conducted during latter part of last year, and study of location of various traffic centers. Third article.

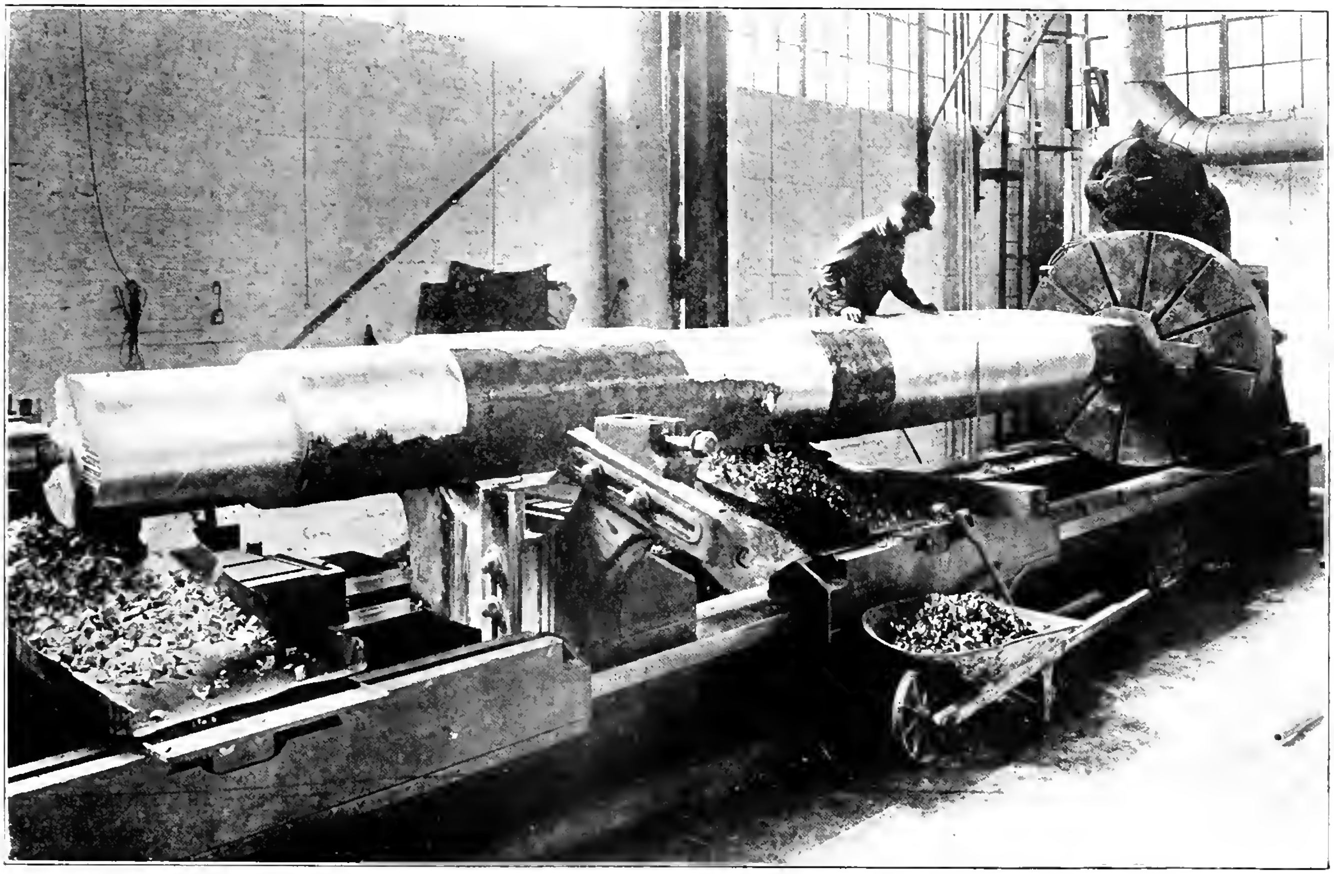
Troughwork

Troughwork and Other Protection, G. H. McKelway. Elec. Traction, vol. 15, no. 3, Mar. 15, 1919, pp. 172-176, 6 figs. Methods of installing various kinds of troughwork and protection for overhead structures and other construction above trolley wire.

Wartime, Europe

Continental Tramways in War-Time—II. Elec. Ry. & Tramway Jl., vol. 40, no. 961, Mar. 7, 1919, pp. 85-90, 2 figs. Repair shops of General Omnibus Co. and Metropolitan Railway.

CAMDEN



JUST AS

quick work is made of the ox going to the slaughter, so we secure speed in the machining of the

CAMDEN FORGINGS

made in our press and hammer shops.

We're well and largely equipped so that forgings ranging in weight from 100 to 60,000 pounds are all "Grist for our Mill."

Here are some of the things we make—

BUYERS' MEMO

High and Low Carbon Bars
Press Columns and Rams
Pull Back Cylinders
Water Cylinders
Valve Bodies
Plungers
Weldless Steel Rings
Lathe Spindles, solid and hollow bored
Long Feed Screws
Power Press Crank Shafts
Rudder Arms

Rudder Stocks
Cam Shafts
Eccentric Shafts
Crusher Shafts
Gear and Pinion Blanks
Locomotive: Side and Main Rods; Crank Pins; Axles; Rod Straps; Guides; Parts of frame both in iron and steel

Hammered Iron Bars for locomotive repairs
Marine Shaft
Marine Connecting and Eccentric, Rods
Rolls: Bending; Feed; Straightening; *Embossing*
Large Wrenches
Saw Arbors

Steam Engine Forgings
Pump Crank Shafts
Pump Connecting Rods
Large Nuts
Turbine Shafts
Mill Shafting
Trolley Car Axles
Electric Motor Axles
Any forging to your print, and specifications, in either iron or steel

CAMDEN FORGE CO.
CAMDEN, N.J., U.S.A.

Zone Systems

Zone System for New Jersey. Elec. Ry. Jl., vol. 53, no. 11, Mar. 15, 1919, pp. 523-528, 2 figs. Details of the petition of public service railways to Public Utility Commission.

How the Public Service Railway Established and Will Collect Its Zone Fare. Elec. Ry. Jl., vol. 53, no. 12, Mar. 22, 1919, pp. 598-604, 9 figs. Company proposes to put a ticket-issuing machine on front platform by which each passenger will receive a check indicating the zone in which he boards the car, then he pays the appropriate fare as he leaves by the rear platform.

The Zone Fare in Practice—Glasgow, Walter Jackson. Elec. Ry. Jl., vol. 53, nos. 10 and 13, Mar. 8 and 29, 1919, pp. 446-453, and 632-638, 15 figs. Layout of tramway system, service on different lines as regards speed and headways and application of graded fare. Second article. Mar. 29: Considers standard double-deck car, the make-up of schedules, the hours and rates of pay of transportation employees and the checking and auditing of the differential system of graded fares.

Munitions and Military Engineering

Aberdeen Ordnance Proving Ground

History of the Aberdeen Ordnance Proving Ground III, F. P. Lindh. Am. Mach., vol. 50, no. 13, Mar. 27, 1919, pp. 607-611, 4 figs. Development of railway artillery, meteorological work and airplane bombing. Concluding article.

Construction Division

The Construction Division of Our Army, George W. Fuller. Eng. News-Rec., vol. 82, no. 9 and 10, Feb. 27, and Mar. 20, 1919, pp. 416-419 and 562-564. Organization and work accomplished. Mar. 20: Details of organization; plea for continuance as independent unit of military establishment.

Trains, Armored

Armored Trains for Coast Defense. Engineer, vol. 127, no. 3294, Feb. 14, 1919, pp. 150-162, 6 figs. Engine is in middle of train, infantry vans on either side of engine, and gun carriage at ends.

Engineering Activities

Civil Engineering in the War, George K. Scott-Moncrieff. Times Eng. Supp., vol. 15, no. 532, Feb. 1919, pp. 65-66. Rapidity in erecting of construction work.

Engineering Achievements of the Army. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 372-374, 5 figs. Activities in railroading, bridges, searchlights, map production and forestry operations.

Fire Control

On a New Application of Viscosity (Sur une application nouvelle de la viscosité), Georges Claude. Comptes rendus des séances de l'Académie des Sciences, vol. 168, no. 5, Feb. 3, 1919, pp. 274-276, 2 figs. Apparatus utilizing viscous liquid for regulating firing of projectiles.

Gas Water

The Development Division, Chemical Warfare Service, U.S.A., F. M. Dorsey. Jl. Indus. & Eng. Chemistry, vol. 11, no. 4, Apr. 1, 1919, pp. 281-287, 8 figs. How development division developed gas masks for protection of American soldiers.

Production of Gas Defense Equipment for the Army, Bradley Dewey. Jl. Indus. & Eng. Chem., vol. 11, no. 3, Mar. 1, 1919, pp. 185-197, 20 figs. Plant, organization, divisions and operations involved in manufacture of gas masks.

Gun Manufacture

How the 155-Mm. Howitzer Is Made—VII, J. V. Hunter. Am. Mach., vol. 50, no. 13, Mar. 27, 1919, pp. 587-593, 23 figs. Methods used in producing breech mechanism, with reference to tolerances permitted.

Making the U. S. 75-Millimeter Field Gun, Erik Oberg. Machy., vol. 25, no. 7, Mar. 1919, pp. 624-630, 27 figs. Methods developed by Wisconsin Gun Co. in producing light field artillery. First article.

Manufacturing the 4.5-Inch British Howitzer III, J. H. Garrett. Machinery, vol. 13, no. 335, Feb. 27, 1919, pp. 589-596, 22 figs. Austin Motor Company's methods of production.

Gunnery

Notes on Gunnery, O. A. Randolph. Univ. Colo. Jl. Eng., vol. 15, no. 2, Jan. 1919, pp. 20-28, 6 figs. Classification of guns and projectiles; interior ballistics; factors which influence the trajectory.

Guns, Long-Range

A 121-Mile Gun, J. Bernard Walker. Sci. Am., vol. 120, no. 13, Mar. 29, 1919, pp. 312-313, 4 figs. Theoretical study of a 10-in. gun with a range of 121.3 miles.

Guns, Naval

Heavy Naval Gun is Given Field Mounting, C. M. McCrea. Iron Trade Rev., Vol. 64, no. 11, Mar. 13, 1919, pp. 707-709, 3 figs. Caterpillar mounting of 7-in. naval gun.

Illuminating Engineering

The Illuminating Engineer at War, George H. Stickney. Tran. Illum. Eng. Soc., vol. 13, no. 9, Dec. 30, 1918, pp. 439-447. Reviews work of society during war.

Monitors

The British Monitors, Engineer, Vol. 127, no. 3294, Feb. 14, 1919, pp. 143-145, 7 figs. Purpose and details of ships.

Mounts for Large Guns

Heavy Field Pieces with Mobile Mount, C. L. McCrea. Mech. Eng., vol. 41, no. 4, Apr. 1919, pp. 375-376, 1 fig. On design and construction of caterpillar mount of high-power 7-in. gun by Navy Bureau of Ordnance.

Railway Mounts for Large Naval Guns. Ry. Rev., vol. 64, no. 13, Mar. 29, 1919, pp. 477-480, 5 figs. History of organization, construction details and work of naval batteries in France.

Making Naval Gun Mounts, Franklin D. Jones. Machy., vol. 25, no. 7, Mar. 1919, pp. 600-605, 12 figs. Special tools, gages and fixtures used at the plant of the Mead-Morrison Mfg. Co. for construction of 1000 complete mounts for 4-in. guns for U. S. Navy. Second installment.

Munition Plants

How a Munitions Plant Was Built and Operated in Canada, Using Tons of Copper and Zinc Each Day. Brass World, vol. 15, no. 3, Mar. 1919, pp. 71-73, 3 figs. Organization work of Imperial Munitions Board.

Paravane

The Protection of Ships Against Mines. Engineer, vol. 127, no. 3297, Mar. 7, 1919, pp. 222-224, 5 figs. Arrangement of paravanes, or towed devices for cutting mine mooring wires, on a merchant ship. First article.

The Mysterious Paravane, William Washburn Nutting. Int. Mar. Eng., vol. 24, no. 4, Apr. 1919, pp. 289-293, 7 figs. How machine countered German mines.

Central-Station Heating in Detroit

By J. H. Walker,[1] Detroit, Mich.

This paper discusses the general problem of the utilization of the heat ordinarily discharged to the condensing water in a central electric generating station. The impossibility of its complete utilization for the purpose of heating buildings and the difficulties in the way of even its partial utilization are pointed out, with particular reference to conditions existing in Detroit.

The development of the central heating system of the Detroit Edison Company is traced, showing how the use of exhaust steam for heating was abandoned in favor of live steam. The reasons why it is more commercially expedient under the existing local conditions to supply live steam to the heating system and to generate all electric current in the condensing stations, are also fully brought out.

The latter part of the paper describes some interesting features of the central heating system in Detroit, such as the boiler plants, distributing system, underground construction of pipes and tunnels, consumers' installations and meters. Special mention is also made of the method of transmitting steam through feeders at high velocities and with large pressure drops.

The complete paper concludes with a discussion of the advantages of central heating service and of the obstacles to its wider use. It also points out the possibility of operating individual plants in combination with the central plant.

ONE of the natural results of the grouping together of human beings, in civilized communities is the existence, in our cities, of central plants for the generation and distribution of heat to surrounding buildings. The advantages of central heating service to the user, over the alternative of operating a heating plant in his own building are comparable to those accompanying any other public service. To the community, also, a properly operated central heating plant is a distinct asset, commercially and economically.

Started in a limited way about forty years ago, the central heating industry has grown steadily, though not with the rapidity of some other utilities, until at the present time there are between two and three hundred enterprises operating as public utilities in cities of all sizes in most of the northern states and doing an annual gross business estimated at from ten to fifteen million dollars. The capital invested is perhaps thirty to forty million dollars. As media for distributing the heat both hot water and steam are used, but because of the impracticability of metering hot water and because of the greater adaptability of steam to the requirements of the average building the trend of progress is toward the later. Further development of the business now hinges mainly upon the possibility of the establishment of the proper relationship between rates and the cost of service so as to insure adequate return upon invested capital. In many instances this relationship is not satisfactory at present, chiefly because the actual cost and the value of the service are not known. The engineering practicability has been amply demonstrated; and that there is a pronounced economic demand for the service is beyond question.

The central heating business is closely allied with the electricity supply business and in most cities is carried on directly or indirectly by the electricity supply companies. The task of supplying the demand for heating service falls quite naturally to the electric company because of the partial similarity in the methods of production and distribution of the two commodities; and because the ability to offer to its prospective customers both electric and heating service, with the consequent entire elimination of any sort of power plant from the customer's building, is of great advantage to an electric company doing business in a large city.

Other reasons for the combining of the two utilities are the economies in the consumption of fuel, and to some extent in the investment costs, which are sometimes made possible by the physical combination of the electric and heating plants.

The heat carried away by the condensing water in the central electric stations of the United States, equivalent to about 60 per cent of the total fuel burned by them, is one of the more obvious, although not by any means the greatest, wastes of the country's resources. Like many other similar losses this one exists, not because its reduction is theoretically impossible but because it is seldom commercially practicable. But although commercial considerations have always dictated certain practices in the utilization of fuel and will continue to do so in the future, the increasing cost

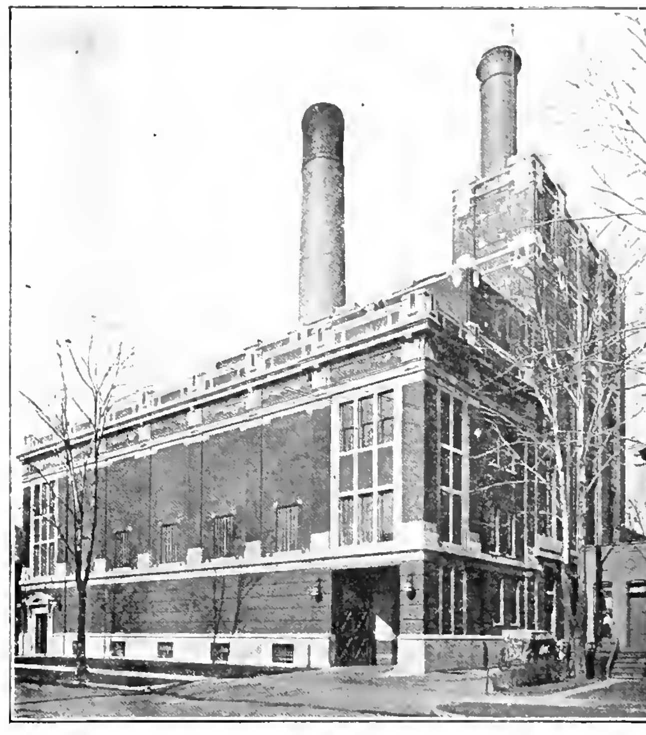

Fig. 1 Willis Avenue Central Heating Plant

of coal and the present impulse toward its conservation now direct attention to some of the fundamental problems involved.

This great quantity of heat, rejected at low temperature from the generating units, may be considered as a by-product of electricity supply and as such its rate of production will depend upon the rate of production of electricity, the primary product. The complete utilization of any by-product becomes possible only when an outlet for it exists or can be created. Moreover, since neither electrical energy nor heat can be stored to any great extent, it is necessary for the complete recovery of this by-product that the demand for it be equivalent, hour by hour, and day by day, to the rate of electricity supply. The warming of the interior of buildings is of course a natural means of utilizing this heat, but the great diversity in the rate of use of the two commodities renders impossible even an approximately complete realization of the theoretical economy. The lack of agreement in their use from week to week throughout the year is illustrated in Fig. 2, in which the 1918 load curves for electrical and heating service in Detroit are plotted to a percentage scale with the maximum point on each curve taken as 100 per cent.

The possibility of establishing a better relation between the rates of use is rather slight. The rate of heat supply is largely

[1] With Detroit Edison Company, Detroit, Mich.

For presentation at the Spring Meeting, Detroit, Mich., June 16 to 19, 1919, of The American Society of Mechanical Engineers. Contributed by the Detroit Section. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

fixed by unalterable climatic conditions. The use of electricity for lighting is also governed by natural elements. The demand for electricity for industrial use, which now constitutes a major fraction of the output of most central stations is not governed by these factors, and is the only kind of load whose characteristics could conceivably be adjusted to suit the requirements for exhaust heat and even this could probably not be done to any practicable extent.

Another important obstacle to the full use of this by-product heat through the warming of buildings is due to the great development of the central electric stations which in many industrial centers in the United States have so increased in size that the amount of exhaust heat which would be available as a by-product is greatly in excess of that which it would be commercially feasible to distribute

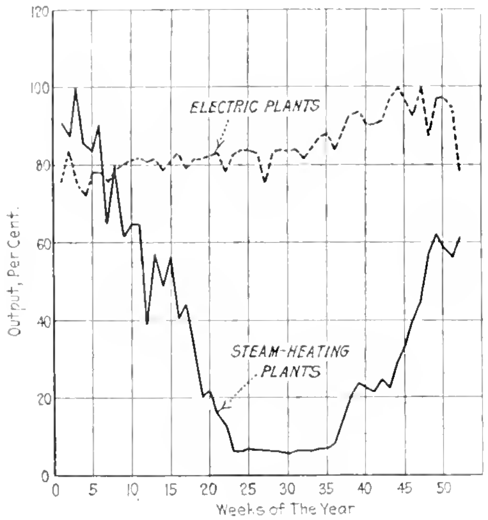

Fig. 2 Load Curves of Electric and Steam-Heating Plants

for the heating of buildings. For example, in 1918, the central electric-generating stations in Detroit produced approximately 774,000,000 kw.-hr. of electricity. The exhaust steam which would have been available if discharged at pressures above atmosphere and which could have been utilized for heating, considering the winter months only, would have amounted to over 9,000,000,000 lb. This is five times the quantity actually distributed in the existing central heating system of the city, which entirely covers the only portion of the city in which the heating load is sufficiently dense to render the laying of distribution mains commercially justifiable. For because of the great investment costs the distribution of heat by the medium of steam is feasible only in the districts of relatively great density of load, which, in most of our cities, comprise only the business district and the very best residence districts. Nor are the economies to be gained by using by-product heat sufficient to enlarge this area appreciably. The central heating business in the average American city could keep pace with the electricity supply business only if the density of population were far greater than is compatible with present standards of living.

Thus it is apparent that the exhaust heat from central electric stations can at best be utilized for heating only during the times when heat is required and then only in so far as it can be commercially distributed. But there are certain obstacles which stand in the way of its utilization even to this extent—obstacles which arise primarily from the difficulty of transmitting steam over long distances.

Systems of Central Heating

Assuming that a central heating load exists and is to be supplied by the electric company, there are in general three methods by which this can be done:

1 The heating load can be served from a condensing generating station so designed that steam is available for heating at pressures above atmosphere after partial expansion in the electric-generating units, the remainder of the steam used for current generation being fully expanded and condensed at high vacuum.

2 Separate heating plants may be built in locations near the heating load and equipped with non-condensing generating units which will generate current only to the extent of the requirements for exhaust steam for heating, the remainder of the electricity being produced in a condensing station.

3 The heating system may be supplied entirely with live steam from boiler plants located near the center of the heating load.

It may so happen that the natural location for the main generating station serving a city is near the heating load, and if this is the case, the first method is preferable. Often, however, a consideration of land values or of railroad connections requires that the main condensing station be located at such a distance from the heating load as to preclude the possibility of transmitting steam from it. This is the case in Detroit. The Delray plant and the Connors Creek plant, the two main generating stations operated by The Detroit Edison Company, are respectively $3\frac{1}{2}$ and $4\frac{1}{2}$ miles from the heating district. A condensing plant, located on high-priced land near the heating district and with inconvenient railroad connections, or none, would be necessary if this first method were to be used. To such a plant, built for electricity supply and consequently, for reasons previously stated, burning more coal than a plant built solely for heating, this matter of proper railroad facilities is particularly important. Here again enters the matter of the transmission of steam, for the size of the pipes required to transmit a given quantity of steam over a given distance decreases as the density of the steam and the amount of pressure drop along the pipe increase. The most economical method from the standpoint of investment costs would

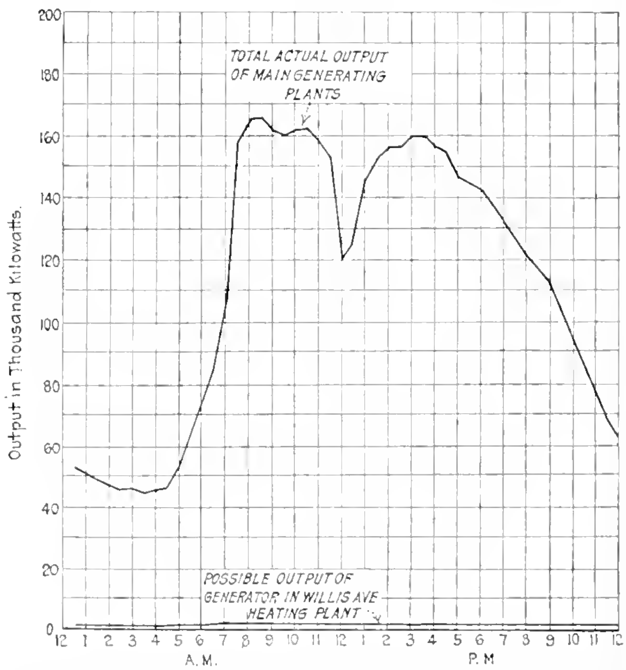

Fig. 3 Load Curves Showing Possible Electric Output of Heating Plant as Compared with Output of Main Station

be to extract steam from the high-pressure stages of the turbine; but the amount of electricity which could be generated per pound of steam would then be reduced.

In Detroit many of these conditions conspire to make the use of exhaust steam for heating unattractive. Generating units exhausting into the heating mains were operated in one of the heating plants for several years, but this practice has since been definitely abandoned and the heating system is now being supplied with live steam. Current generation is limited to the output of small house-service turbo-generators whose exhaust is utilized to heat the feedwater. The history of the central heating industry in Detroit is one of steady progress toward this method of live-steam operation.

Development of Central Heating in Detroit

The immediate motive which, in 1903, led to the establishment of the central heating industry in Detroit was the possibility of obtaining a high thermal efficiency in the generation of electricity through the utilization of the exhaust steam. The generating plant from which steam was first supplied for heating had previously discharged its exhaust to the atmosphere. Owing to the building, at this time, by The Detroit Edison Company, of a large condensing plant, the smaller plant, with several others, would have been shut down, but the possibility of selling the exhaust steam made it appear desirable to continue the generation of current there to the extent of the exhaust-steam requirements. Also, since the plant was located in a district served with direct current the loss involved in converting an equivalent amount of alternating current received from the main plant to direct current would be saved for such current as might be generated there. The plant was in a high-class residence district and the heating service proved very popular, but the actual overall economy of the plant was not as great as had been anticipated.

A year later the construction of a central heating plant was begun in the business district of the city. This second project was undertaken, not as a means of disposing of exhaust steam, but for the express purpose of supplying the demand for central heating service among the owners of downtown buildings who were considering shutting down their plants and purchasing electric service. The downtown plant was built primarily as a heating plant and though provision was made for electric generating units they were never installed and the heating mains were supplied with steam from the boilers through reducing valves.

With the development of the large condensing generating stations the generation of current in the heating plants grew less and less attractive and when a third heating plant became necessary because of increasing demand for steam heat no provision was made for electric generators. The same practice was followed when, in 1916, the original exhaust-steam plant was rebuilt; and when the steam distribution system of another company which had been engaged in the generation of electricity and the distribution of exhaust steam in the business district was purchased by The Detroit Edison Company the new plant which was built to supply this district was also designed as a heating plant only. The entire combined distribution system is now being supplied with live steam from the boilers through reducing valves.

Since there are no generating units exhausting into the heating system the pressure carried on it is not limited by considerations of back pressure. On those sections of the system formerly supplied with exhaust steam at from 2 to 5 lb. pressure, the pressure now maintained ranges from 5 to 15 lb. and is being increased from year to year, toward the upper limit permitted by the strength of the pipes. The pressure on the section originally designed as a live-steam system is about 30 lb. Because of the increased capacity of the distribution system at higher pressures, due to the greater density of the steam and the greater allowable pressure drop, these higher distribution pressures are desirable.

The steam is delivered to the network of mains through connections made at the plants and also through feeders, from the plants which deliver steam to certain feeding points in the distribution network, the method being similar to the feeder and main method employed in electric distribution systems.

Reasons for Using Live Steam in Detroit

The supplying of live steam to the heating system and the abandonment of the generation of current in the heating plants is commercially justifiable, even though such current would be generated at a high thermal efficiency. The underlying reason for this is that there exist certain unfavorable conditions which outweigh the thermal advantage and make the total cost of such current higher than the generating cost at the large and efficient main generating stations.

In considering the cost of generating current, when the heat in the exhaust is recovered, it should be borne in mind at the outset that the amount of coal consumed, though small, is not by any means negligible as compared to that consumed in a condensing station. For each kw-hr. so generated, there would be extracted from the steam, if the conversion were 100 per cent efficient, its heat equivalent 3415 B.t.u. Taking into account mechanical and electrical losses in the generating unit and the losses involved in generating steam from the coal, the actual number of heat units devoted to the generation of electricity is not less than 5700 B.t.u. per kw-hr. This is 27 per cent of the corresponding figure for the Connors Creek plant (a condensing station) which in 1918 generated its total output at an average of 20,900 B.t.u. in the coal per kw-hr. of output. So that at the outset, the additional fuel which would have to be burned in the heating plants if current were generated, would be over one-quarter of the amount required to produce the equivalent amount of current at the Connors Creek plant.

One of the principal elements of cost which militates against current generation in the heating plants is the attendant labor, which, because of the low load factor and small size of any generating units which might be installed there, makes the cost of this item per kw-hr. generated much higher than in the large stations where the size of the units and the load factor are much greater.

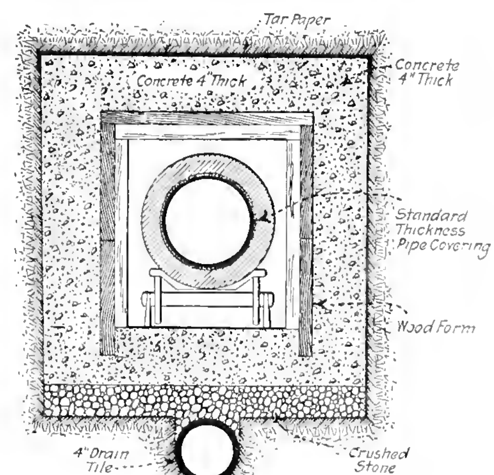

Fig. 4 Underground Steam-Line Construction

But the deciding factors are the investment charges. The change of policy involving the final abandonment of exhaust steam heating was made in 1916, with the rebuilding of the Willis Avenue heating plant, the original exhaust-steam plant. At this time the electrical load in Detroit was increasing rapidly and several new turbine-generator units were being purchased. At the Willis Avenue heating plant the existing and future exhaust steam requirements would have called for a generating unit of about 2000 kw. capacity. The unit purchased at the time for the Connors Creek plant was the 45,000-kw. machine which has since been put into service. Would the existence of small generating units in the heating plants, aggregating altogether possibly 4000 kw., actually reduce the number of machines in the Connors Creek plant at that time or at any future time, if the latter were to increase in steps of this magnitude? Regardless of theoretical considerations, as a matter of fact it actually would not have done so and it became clearly evident, therefore, that any investment in generating units in the heating plants must be reckoned as *additional* investment and the cost of any electricity generated by them must include the fixed charges on that investment and could not be credited with having saved any investment elsewhere. The relatively insignificant proportion of the total system load which could be born by a unit in the Willis Avenue plant is strikingly illustrated in Fig. 3.

The small size of the unit and its low load factor would make

these investment charges relatively high per kw-hr. generated. Furthermore, while the chief advantage of the heating plant generating units would lie in their ability to avoid conversion losses by generating direct current required for the downtown district, this advantage could not be completely made use of because of the lack of coördination between the heating and electrical loads of that district, which would make it necessary to convert some of the direct current back to alternating current for transmission to some other district or else would reduce the load factor of the unit.

For a quantitative economic study of the subject the Willis Avenue heating plant offers a favorable example, for it had been operated as a generating plant and the distribution mains had been designed for exhaust-steam pressures. Based on the performance of the old engine-driven units there would have been generated about 6,000,000 kw-hr. per year.

In accordance with the considerations which have been mentioned, the proposed turbo-generator installation should be

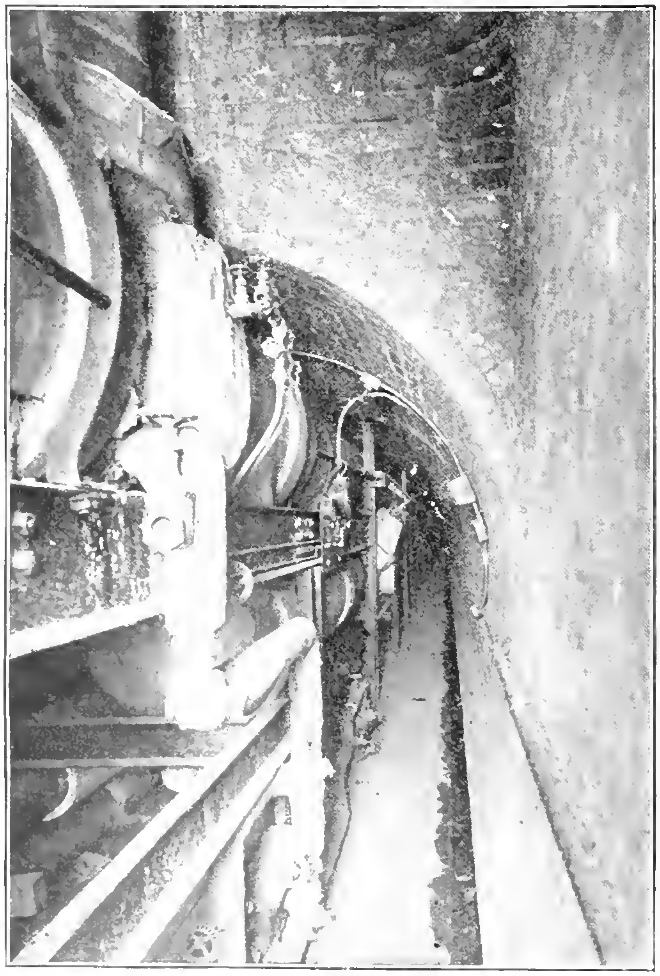

Fig. 5 Tunnel Construction for Steam Lines

charged with its operating and maintenance costs including, labor, supplies, and the fuel equivalent of the energy produced. It should also be charged with the fixed charges on the unit itself and on the building space occupied. Based on the fairly stable pre-war prices existing in 1916, these items might be conservatively estimated as follows, neglecting the disadvantage due to the lack of coördination between steam and electrical loads.

Charges Against Generating Unit (Operation and Maintenance):

Labor (3 oilers)	$3,360
Supplies, etc.	200
Fuel cost (1221 tons at $2.66)	3,247
Maintenance	200
	$7,007

Fixed Charges (Additional Items Only):

2000-kw. turbo-generator at $15 per kw.	$30,000	
Installation cost, wiring and piping	4,000	
Building and foundations	10,000	
	$44,000	
Depreciation at 4 per cent		1,760
Return on investment at 6½ per cent		2,860
Total charge against turbine		$11,627

The turbo-generator must of course be credited with the cost of generating an equivalent amount of energy at the main plant, of transmitting it to the heating plant district, and of converting it to direct current, since these costs would be incurred if the turbo-generator were not installed.

The production cost of electric current generated by a central station consists of two parts, the demand or "readiness to serve" component and the "energy" component. The former may be defined as that portion of the total production cost which would be incurred if no electricity were actually delivered, but if the plant were merely held in readiness to deliver the loads actually sustained, in other words, with steam pressure up, turbines and auxiliaries in motion, a sufficient number of boilers banked and the operating crew on duty. The energy component may be considered as that part of the total cost which is directly proportional to the amount of energy delivered. Although the exact separation of these components is impossible, the distinction between them is none the less real and is one that is generally recognized.

In the present case the heating-plant generating unit can be credited only with energy component, since it is not to be considered as having reduced the size or number of units in the main generating plant. The energy component may fairly be considered as including 75 per cent of the fuel cost, 50 per cent of the cost of maintenance of plant equipment and that part of the labor such as coal handling which may be considered as depending upon the amount of electricity generated, and amounting in this case to 9 per cent.

The actual combined efficiency of transmission to the heating plant district and of conversion to direct current is approximately 80 per cent, so that to deliver 6,000,000 kw-hr. of direct current to the heating plant district there would be generated at Connors Creek 7,500,000 kw-hr.

The credit which can be allowed to the heating plant for the current which it would generate would then be as follows:

Fuel—4112 tons at $2.38	$9,786
Wages	285
Maintenance	617
Total credit allowable	$10,688

This credit of $10,688 compared with the larger figure of $11,627 which is to be charged against the heating-plant unit, thus indicates that the generating of current in the heating plant would not be justified.

The foregoing study, however, is based only upon conditions in the plant itself and no mention has been made of the effect upon the distribution system when exhaust steam is distributed. It is common practice in exhaust-steam systems to carry a back pressure of from 2 to 15 lb. At these pressures the specific volume of the steam is high and the allowable pressure gradient throughout the system is very limited, making it necessary to install much larger pipes than is the case when live steam at higher pressures is used and consequently increasing the investment. While it is true that turbines have been built for exhaust pressures up to 30 lb., the electrical energy which can be extracted per pound of steam under such conditions is reduced and the cost per kilowatt of turbine capacity is increased; furthermore, in the method of feeder operation which is actually employed and which has proved of inestimable value, the pressure of delivery to the feeders is much higher than this.

The method of live-steam operation was adopted in Detroit before the recent great advance in the price of coal. The present high price of coal makes exhaust-steam operation appear somewhat more favorable and it is of course conceivable that at

some future date a very high coal price may compel a change of policy. But with the cost of underground lines also increasing, the saving in distribution investment will probably continue to be sufficient to justify a continuation of the present methods.

Most of the foregoing facts only apply in cases where the generating capacity in the heating plant is negligible in comparison with the main generating stations. If this is not the case, if the discrepancy in size is not great so that investment in the main plants is actually saved, or if the additional current required from the condensing station is actually not produced at a relatively low cost, then the situation may be entirely changed, and there are many instances of this in the United States. The consideration of the steam-transmission investment when low-pressure steam is used is usually controlling, however, and is being increasingly well recognized.

Boiler Plants

The four boiler plants in Detroit which supply steam to the heating system are equipped with water-tube boilers and underfeed stokers and are of modern design throughout. Their location in the central district of the city necessarily restricts the amount of land which they may occupy and demands a suitable type of architecture, absolutely smokeless operation, and extreme cleanliness in the handling of coal and ashes. Fig. 1 shows how these ideas have been carried out in the Willis Avenue plant.
